Alchemy was associated with many religious beliefs. It was believed that the techniques used to make gold were symbolically related to death, corruption, regeneration, and resurrection. Alchemy and astrology became closely related because of the belief that each heavenly body represented and controlled a certain metal. Some thought the sun represented gold; the moon, silver; Mars, iron; Venus, copper; Jupiter, tin; Saturn, lead; and Mercury, the metal mercury, also called *quicksilver.* Alchemists believed that the positions of these bodies influenced the success or failure of their work.

Alcibiades, *AL suh BY uh DEEZ* (450?-404 B.C.), was an Athenian general. He became a central figure in the Peloponnesian War, which was fought between Athens and Sparta from 431 to 404 B.C.

Alcibiades was the ward of the Athenian leader Pericles and a favorite pupil of Socrates, a famous Greek philosopher. He entered politics in 420 B.C. and soon became popular for his aggressive foreign policy.

Alcibiades's policy led Athens to a battle with Sparta in 418 B.C., which Athens lost. Later, he persuaded the Athenians to invade Sicily. In 415 B.C., just before the invasion began, citizens accused Alcibiades of defacing statues of the god Hermes and of mocking the religious rituals known as the Eleusinian Mysteries. The Athenians refused his request for an immediate trial, so he sailed on to Sicily. Shortly after arriving in Sicily, Alcibiades was called back to Athens for trial. But he escaped to Sparta. He advised the Spartans to aid the Sicilians, and the Athenians were defeated in Sicily.

Later, the Spartans grew suspicious of Alcibiades. Alcibiades then became an adviser to the Persian leader Tissaphernes. In 411 B.C., the Athenians asked Alcibiades to lead their fleet at Samos. With this navy, he defeated the Spartans in several battles and became a hero. In 406 B.C., however, the Spartan general Lysander defeated Alcibiades's fleet. After Athens's final defeat in the war, Alcibiades fled to Asia Minor (now Turkey). There, his enemies set fire to his house, and he died trying to escape. Peter Krentz

Alcoa Inc. is the world's leading producer of aluminum products. It maintains operating facilities in more than 100 locations worldwide. Alcoa is engaged in all steps of aluminum production, from the mining of the aluminum ore *bauxite* to the fabrication of aluminum into finished products. Alcoa also has plants for recycling used aluminum. The company's wide range of products includes bars, building products, castings, electrical conductors, fasteners, foil, forgings, plates, rods, sheets, tubing, and wire.

Alcoa is also involved in the shipping industry and in the manufacture of chemicals and nonaluminum products. It licenses technology to other firms and sells engineering and construction services.

The company was organized in 1888 as the Pittsburgh Reduction Company. It was formed to produce aluminum by a process discovered by the American scientist Charles M. Hall in 1886. The company's name was changed to the Aluminum Company of America (Alcoa) in 1907. It adopted its present name in 1999. The company's headquarters are in Pittsburgh, Pennsylvania.

Critically reviewed by Alcoa Inc.

See also Alcan Aluminum Limited; Aluminum (The growth of the aluminum industry).

Alcock and Brown, *AWL kahk,* were pioneer British aviators who made the first nonstop flight across the Atlantic Ocean. Sir John William Alcock (1892-1919) was the pilot, and Sir Arthur Whitten Brown (1886-1948) was the navigator. On June 14, 1919, the two men took off from Lester's Field near St. John's, Newfoundland (now Newfoundland and Labrador), in a twin-engine Vickers *Vimy,* a converted bomber. They landed the plane in a bog near Clifden, Ireland, the next day. They traveled 1,950 miles (3,138 kilometers) in 16 hours 27 minutes at an average speed of 118 miles (190 kilometers) per hour.

Alcock and Brown were knighted for their effort by King George V. They also received a prize of 10,000 pounds ($46,200) that the *London Daily Mail* newspaper had offered to the crew of the first airplane to make a nonstop transatlantic crossing.

Alcock was born on Nov. 6, 1892, in Manchester, England. During World War I (1914-1918), he was considered one of the best pilots in the United Kingdom's Royal Naval Air Service. He died in an air crash on Dec. 18, 1919, six months after his transatlantic flight.

Brown was born of American parents in Glasgow, Scotland on July 23, 1886. He became a British citizen and served in the Royal Flying Corps. He died on Oct. 4, 1948. Paul R. Matt

Alcohol refers to a class of chemical compounds, all of which consist of chemically bonded atoms of carbon, hydrogen, and oxygen. All alcohol molecules contain at least one *hydroxyl group.* A hydroxyl group is a specific

arrangement of atoms in which a hydrogen atom is bonded to an oxygen atom. In alcohol molecules, the oxygen atom in the hydroxyl group is, in turn, bonded to a carbon atom.

People commonly use the word *alcohol* to refer to such beverages as beer, wine, and liquors. But there are many types of alcohols, and they have a variety of uses. This article discusses the chemical properties and commercial uses of several alcohols. For information on alcoholic beverages, see Alcoholic beverage.

Methanol, also called *methyl alcohol* or *wood alcohol,* is the simplest of the alcohols. It has one hydroxyl group, and its chemical formula is CH_3OH. Methanol is a highly toxic, colorless liquid. It boils at 149 °F (65 °C) and freezes at −137 °F (−94 °C).

Methanol originally was produced from wood, but it is now commercially produced primarily from *methane,* the chief component of natural gas. The majority of commercially produced methanol is converted to *formaldehyde,* a chemical used to make plastics. As an industrial *solvent* (substance that dissolves other substances), methanol is important in the manufacture of paints and varnishes. Methanol also functions as a fuel-line antifreeze for automobiles, and it serves as an ingredient in the production of other chemicals. Methanol can be used as a motor fuel, but it is more expensive than other fuels. See Methanol.

Ethanol, also called *ethyl alcohol,* is the alcohol found in alcoholic beverages. Ethanol is also used for a variety of other purposes. It serves as a solvent for chemical reactions and for lacquers, varnishes, and stains. It is also important in the preparation of chemicals used as detergents, flavorings, and fragrances. When ethanol is added to gasoline, it improves the octane rating of the gasoline.

Ethanol is produced by several methods. For example, ethanol used in beverages is produced by fermenting fruits, grains, or vegetables. However, most ethanol used for commercial purposes is made by heating ethylene and water under pressure in the presence of a phosphoric acid catalyst (see Catalysis). Ethylene is a gas that is a component of crude oil.

The United States government controls and taxes the production and distribution of ethanol in the United States and taxes ethyl alcohol used in alcoholic beverages. For this reason, ethanol manufacturers in the United States *denature* (make unfit to drink) most of the ethanol that will be used for purposes other than alcoholic drinks. Manufacturers denature ethanol by mixing it with methanol or other poisonous chemicals.

Ethanol boils at 172 °F (78 °C) and freezes at −173 °F (−114 °C). Its chemical formula is CH_3CH_2OH. It has one hydroxyl group.

Propanol, or *propyl alcohol,* has one hydroxyl group, and its chemical formula is $CH_3CH_2CH_2OH$. There are two forms of propanol, called *isomers.* Isomers have the same kind and number of atoms. However, they have different molecular structures and therefore different chemical and physical properties. For example, one of the isomers of propanol, called *normal propanol, 1-propanol,* or *n-propyl alcohol,* boils at 208 °F (98 °C) and freezes at −195 °F (−126 °C). But the other isomer, known as *isopropanol, 2-propanol,* or *isopropyl alcohol,* boils at 181 °F (83 °C) and freezes at −126 °F (−88 °C).

Normal propanol is made commercially from ethylene and synthesis gas, a mixture of hydrogen and carbon monoxide, in the presence of a rhodium or cobalt catalyst. Propyl alcohol is used to prepare other chemicals, and it is used as a solvent for sticky substances called *resins.*

Isopropanol is produced by reaction of the gas propylene, a component of crude oil, with water in the presence of an acid or metal catalyst. Isopropanol is mainly used to produce acetone, a common industrial solvent. It is also used as a rubbing alcohol, and in cosmetics and lotions.

Ethanediol, or *ethylene glycol,* is a highly toxic alcohol that is used mainly as an antifreeze in automobile radiators. It is produced by the reaction of ethylene with water and oxygen in the presence of a silver oxide catalyst. Ethanediol has a boiling point of 388 °F (198 °C) and a freezing point of −9 °F (−13 °C). It has two hydroxyl groups and a chemical formula of $HOCH_2CH_2OH$.

Other alcohols include *plasticizer alcohols,* which have 6 to 11 carbon atoms. Plasticizers are used in the manufacture of plastics, and they give these substances flexibility.

Alcohols that have more than 11 carbon atoms are called *detergent alcohols.* Manufacturers use these alcohols to make detergents, soaps, and shampoos. In combination with other chemicals, these alcohols have the ability to dissolve dirt and grease in water in a process called *emulsification.* Robert C. Gadwood

Alcohol Problems, American Council on. See American Council on Alcohol Problems.

Alcohol, Tobacco, and Firearms, Bureau of, is an agency in the United States Department of the Treasury. The bureau, which is often called the ATF, has responsibilities for regulation, law enforcement, and tax collection.

The ATF's regulatory mission is to administer federal regulations for the production and distribution of alcohol, explosives, and firearms. ATF regulators inspect factories and businesses and test products. The bureau issues licenses and permits to regulated businesses in the firearms, explosives, liquor, and tobacco industries. Each year, the ATF collects billions of dollars in taxes from manufacturers of alcohol and tobacco.

Most ATF criminal cases involve people suspected of the illegal possession and use of firearms and explosives. Targets of investigation include killers for hire, gun smugglers, bombers, and arsonists. ATF special agents go undercover to break up illegal commerce in firearms, drug smuggling rings, outlaw motorcycle gangs, and other criminal groups. The ATF works closely with other law enforcement agencies.

The ATF was chartered in 1972. Its headquarters are in Washington, D.C. Franklin E. Zimring

Alcoholic beverage is a drink that contains ethyl alcohol. Alcoholic beverages are made chiefly from such grains as barley, corn, and rye, or from grapes or other fruits.

There are two main groups of alcoholic beverages, *fermented drinks* and *distilled drinks.* Fermented drinks contain from 5 percent or less to 20 percent ethyl alcohol. The principal fermented beverages are beer and

wine. Distilled beverages, also called *spirits* or *liquor,* contain from 12 to 55 per cent or more ethyl alcohol. They include brandy, gin, rum, vodka, and whiskey. Americans drink about 5¾ billion gallons (21.8 billion liters) of beer, 570 million gallons (2.2 billion liters) of wine, and 416 million gallons (1.6 billion liters) of spirits annually. The United States ranks about 20th among nations in the *per capita* (per person) consumption of alcoholic beverages.

Taxes on alcoholic beverages provide a major source of revenue for the United States government and state and local governments. About 56 per cent of this revenue comes from the sale of spirits, which carry much higher taxes than do fermented beverages. Taxes and other fees make up approximately half the price of a bottle of spirits.

Ethyl alcohol slows the activity of the nervous system. Alcoholic beverages have a relaxing effect that many people find pleasurable. However, an excessive amount of alcohol can cause intoxication. Prolonged, excessive drinking of alcoholic beverages may lead to alcoholism and various other disorders.

Fermented beverages

Beer, wine, and other fermented alcoholic beverages are made by adding yeast to certain substances that contain sugar. The yeast begins the fermentation process, which converts the sugar into ethyl alcohol and carbon dioxide gas.

Beer is made chiefly from *barley malt.* To obtain the malt, brewers soak barley in water and make it sprout. Then they dry the barley and remove the sprouts, leaving only starch, or malt. The malt is ground and mixed with water to form a *mash.* It is then added to another mash, a preparation of cereal grain such as corn or rice that has been crushed and heated. This process converts the starch into sugar. Dried flowers from the hops plant are added for flavor, and then the mash is fermented. Finally, brewers age beer for several weeks to develop its taste.

Most beer contains from 2 to 6 per cent alcohol. *Lager beer,* the most popular type in the United States, has a golden color, but some beers are dark brown. Beer is a foaming, carbonated beverage and is generally served chilled.

Wine. Almost all wine is made from grapes, which consist largely of sugar. Wine can also be made from apples, cherries, or other fruits. Winemakers crush the fruit and then ferment the juice. Wine may be aged for four years or longer. Most wine has an alcohol content of 7 to 24 per cent. Wine may be red, white, or *rosé* (pink), and either sweet or *dry* (unsweet). Wine is served chilled or at room temperature.

Other fermented beverages include *ale, hard cider,* and *sake.* Ale is brewed in much the same way as beer. Hard cider is made from apples. Sake is a Japanese drink made from rice.

Distilled beverages

Distilled alcoholic beverages are made chiefly from fermented grain mash or fermented fruit juice. In the distillation process, the mash or juice is heated, giving off vapors of alcohol. Distillers collect the vapors and cool them to form a liquid. The flavor of spirits depends largely on the kind and amount of grain, fruit, and yeast used, plus variations in the fermentation, distillation, and aging processes.

The percentage of alcohol in distilled beverages is expressed as *proof.* In the United States, proof equals twice the amount of alcohol in the beverage. For example, a beverage that is 80 proof contains 40 per cent alcohol. In Canada and Great Britain, the amount of alcohol is about 57 per cent at 100 proof.

The leading distilled beverages in the United States include, in order of popularity: (1) whiskey, (2) vodka, (3) liqueurs, (4) gin, (5) rum, and (6) brandy.

Whiskey is made chiefly from barley, corn, or rye. Most whiskey is a blend of as many as 40 kinds of whiskeys made from different grains. Whiskey may be aged six years or more. Aging develops the flavor and gives the beverage an amber color. Whiskey from Scotland, called *Scotch whisky* or just *Scotch,* is known for its smoky flavor. It is made from a mash that consists primarily of barley. Whiskeys made in the United States include *bourbon* and *blended whiskey.* Bourbon is produced from a mash consisting chiefly of corn. American blended whiskey may contain many different types of whiskeys.

Most whiskey ranges from 80 to 100 proof. Whiskey served *straight* or *neat* is served unchilled. Whiskey may also be served *on the rocks* (with ice) or mixed with water, carbonated water, or other beverages. In addition, it is used in many kinds of cocktails.

Vodka is made from barley, corn, or rye, or sometimes from potatoes. It varies from 80 to 100 proof, is not aged, and has no color. Vodka also has no taste or odor, and so it is usually mixed with orange juice, tomato juice, tonic water, or some other beverage.

Liqueurs, also called *cordials,* are made by flavoring brandy, gin, or other spirits with various parts of plants, such as flowers, fruits, and leaves. Liqueurs contain at least 2½ per cent sugar. The most popular flavors include apricot, blackberry, cherry, chocolate, peach, and peppermint. Liqueurs range from 25 to 110 proof and have a variety of colors. They may be served neat, on the rocks, or as part of various cocktails.

Gin is a mixture of alcohol and water, flavored with juniper berries and other ingredients. Gin varies from 80 to 94 proof. It can be mixed with a wine called *vermouth* to make a martini, one of the most popular cocktails. Gin also may be mixed with lime juice, tonic water, or other beverages.

Rum is made from the juice or syrup of sugar cane, or from molasses. Rum is at least 80 proof and may be white or amber, depending largely on the aging process. It is usually mixed with coconut juice, lime juice, pineapple juice, cola, or some other beverage.

Brandy is distilled from grape wine or other fermented fruit juices. Brandy made from grape wine is at least 80 proof. A grape brandy called *cognac* is distilled in the area of Cognac, a town in France. Brandy is aged for two to eight years. Flavored brandies, made from such fruits as blackberries, cherries, or plums, are at least 70 proof. They are named for the fruit whose juice is used in making them. Brandy is usually served neat or mixed with another spirit, such as a liqueur.

Other distilled beverages include *aquavit* and *tequila.* Aquavit, also spelled *akvavit,* is a Scandinavian

beverage made from grains or potatoes and flavored with caraway seeds. Tequila, a Mexican drink, is distilled from the fermented juice of the maguey plant.

History

The first alcoholic beverages were fermented. Scenes showing fermentation appear on pottery made in Mesopotamia as early as 4200 B.C. Brandy is probably the oldest distilled beverage. It may have been made as early as A.D. 100. By the 1400's, whiskey had been distilled in Ireland and Scotland. Gin was first made by a Flemish physician in the 1600's. The first distillery in what is now the United States was established in 1640 in the area of present-day New York City. Rum was first distilled in Barbados about 1650. The first Canadian distillery was established in Quebec City in 1769 for the production of rum. In 1789, the first bourbon was made near Georgetown, Kentucky.

During the 1800's, a movement began in the United States to prohibit the manufacture and sale of alcoholic beverages. A constitutional amendment banning the beverages went into effect in 1920, but thousands of Americans defied the prohibition law. In 1930, the federal government estimated that about 800 million gallons (3 billion liters) of alcoholic beverages were being produced in the country annually. The prohibition amendment was repealed in 1933.

Throughout history, there have been attempts to prohibit or limit the drinking of alcoholic beverages. Countries have imposed various measures to limit alcohol use. These measures include rationing alcoholic beverages, imposing legal bans against drinking, and taxing alcoholic beverages heavily. Some religions prohibit the consumption of alcohol. Lisa M. Tate

Alcoholics Anonymous (A.A.) is a worldwide organization of men and women who help each other solve their common problem of alcoholism. They also offer to share their recovery experiences with others who have a drinking problem and want to do something about it. The fellowship of Alcoholics Anonymous was founded in 1935. It has about 85,000 local groups in the United States, Canada, and about 130 other countries. The people in each group meet to share their problems and experiences. A.A. is not a medical or religious organization. It is concerned only with the personal recovery and continued sobriety of individual alcoholics who turn to A.A. for help. The General Service Office is the center of A.A. activities. The organization's headquarters are in New York City. See also Al-Anon. Critically reviewed by Alcoholics Anonymous

Alcoholism is a serious disease in which people have an overwhelming desire for the mental and physical effects of drinking alcoholic beverages. The formal term for alcoholism is *alcohol dependence.* Alcohol is one of the most widely used drugs in the history of the world. Many adults drink alcoholic beverages on social or ceremonial occasions but have no wish to consume large amounts regularly. People with alcoholism, who are called *alcoholics,* feel a strong, continuing urge to drink.

Alcoholism has four main symptoms: (1) craving, (2) lack of control, (3) physical tolerance, and (4) physical dependence. Craving is a strong need to drink in spite of serious harmful consequences, such as drinking-related illnesses or job problems. Lack of control is the inability to stop drinking once a drinking episode starts. Physical tolerance is the need to consume increasing amounts of alcohol to feel its effects. Physical dependence occurs when people's bodies become so accustomed to alcohol that they have withdrawal symptoms after they stop drinking. Symptoms of withdrawal include shakiness, rapid heartbeat, nausea, sweating, and anxiety. Physical dependence does not occur in all alcoholics.

People who are not alcoholics may also have serious problems caused by excessive drinking. These problems include difficulties at work or school, neglect of family responsibilities, and strains in personal relationships. Drinking that causes problems but does not meet the formal definition for alcoholism is called *alcohol abuse.*

Causes of alcoholism. Scientists do not yet fully understand what causes alcoholism. Although many people use alcohol at times, only a small percentage develop drinking problems. Researchers are beginning to identify ways that the brains of alcoholics differ from the brains of nonalcoholics. For example, tests show that alcoholics and nonalcoholics have different patterns of brain electrical activity. Such differences may provide evidence that alcohol does not affect the brains of alcoholics in the same way it affects nonalcoholics. Because of the way their brains respond, problem drinkers may develop an unusually strong desire for alcohol's effects.

Research shows that heredity plays an important role in alcoholism. For example, the pattern of brain electrical activity associated with alcoholism appears to be inherited. Other studies show that people with an alcoholic parent have a greater risk of developing the disease than do children of nonalcoholics. Scientists are working to identify the particular *genes* (chemical units of heredity) that increase risk. Most experts think that many genes are involved and that environment also plays a key role in developing the disease. Environmental influences may include income level, family stability, and community acceptance of drinking. Experts think that the relative importance of various genes and environmental factors may differ among individuals.

Other research focuses on understanding how alcohol affects *neurotransmitters,* chemicals that carry messages among nerve cells. Studies show that alcohol affects many neurotransmitters in the brain, including *dopamine* and *serotonin.* Among other messages, these chemicals carry information about pleasure, sadness, and other moods. Prolonged drinking changes levels of neurotransmitter activity, and the levels do not immediately return to normal when drinking stops. As a result, problem drinkers may not "feel right" when they stop drinking because their neurotransmitters have adapted to alcohol.

Effects of alcoholism. Alcohol affects the entire body. Health problems caused by long-term drinking include damage to the brain, stomach, intestines, and heart. Liver problems, including a disorder called *cirrhosis,* are especially common in alcoholics. The liver plays a key role in breaking down alcohol, and excess drink-

ing puts abnormal demands on the organ. When alcoholics stop drinking, some experience a severe form of withdrawal called *delirium tremens.* Delirium tremens is a state of extreme confusion that is sometimes accompanied by *hallucinations* (seeing or hearing things that are not really present). Drinking is also a factor in many vehicle crashes, falls, and other accidents.

Treatment aims to help alcoholics stop drinking and remain sober. Behavioral treatments and medications are two important approaches that have succeeded with some alcoholics. Behavioral treatments include participation in Alcoholics Anonymous (A.A.) and various types of counseling. Medications include tranquilizers called *benzodiazepines,* sold under such trade names as Librium and Valium. Benzodiazepines are used in the first few days after a person stops drinking to help prevent symptoms of withdrawal. Another medication called *naltrexone* may be prescribed for longer periods in combination with counseling. For many people, naltrexone lessens the craving for alcohol. A medication called *disulfiram,* sold under the trade name Antabuse, discourages alcohol use by causing nausea, vomiting, and other unpleasant symptoms when people drink.

Alcott, *AWL kuht* or *AWL kaht,* **Bronson** (1799-1888), was an American social reformer and a leader of a philosophical movement called Transcendentalism. From 1834 to 1839, Alcott operated the experimental Temple School in Boston. He tried to develop the bodies and spiritual natures—as well as the minds—of his students.

Alcott was a leading abolitionist. He opposed the Mexican War (1846-1848) because he felt it resulted from a desire by the United States government to extend slavery into Texas. In the 1840's, Alcott helped found two cooperative experimental communities—the socialist Brook Farm and the vegetarian Fruitlands.

Amos Bronson Alcott was born near Wolcott, Connecticut. He was the father of Louisa May Alcott, who wrote the famous novel *Little Women.* John Clendenning

See also Brook Farm; Transcendentalism.

Alcott, *AWL kuht* or *AWL kaht,* **Louisa May** (1832-1888), was an American author. Her best-known book, *Little Women* (1868-1869), tells the story of four sisters growing up in a New England town during the mid-1800's. Alcott also worked to gain voting rights for women and was active in the *temperance* (antidrinking) movement.

Alcott was born in Germantown, Pennsylvania, but she grew up in Boston and Concord, Massachusetts. Her father, Bronson Alcott, was a philosopher and educational reformer. The family's friends and neighbors included the writers Ralph Waldo Emerson, Margaret Fuller, Nathaniel Hawthorne, and Henry David Thoreau. William Ellery Channing, a prominent Unitarian minister, was also a friend. All these people influenced Alcott and helped form her ideas about politics and social reform.

Chicago Historical Society

Louisa May Alcott

Alcott spent most of her childhood in poverty because her father invested in many idealistic projects that failed. At an early age, she began to help support the family by working as a seamstress, a household servant, and a teacher. Her first book, *Flower Fables* (1854), consisted of fairy stories she made up to tell one of her students.

Alcott's first novel, *Moods,* was published in 1864. She became editor of *Merry's Museum,* a magazine for girls, in 1867. That year, a publisher urged her to write a book for girls. She wrote *Little Women,* which became an immediate success. The income from sales of *Little Women* gave her financial security. In *Little Women,* Alcott gave American juvenile fiction an enduring family story, a new kind of girl character, and a less instructive narrative style. The March family in the book is largely the Alcott family. Jo March, the central character, is Louisa. The author continued the story of the March family in *Little Men* (1871) and *Jo's Boys* (1886).

Alcott's other books for young readers include *An Old-Fashioned Girl* (1870) and *Eight Cousins* (1875). She also wrote novels for adults, including *Work: A Story of Experience* (1873) and *A Modern Mephistopheles* (1877), but these were less successful. Alan Gribben

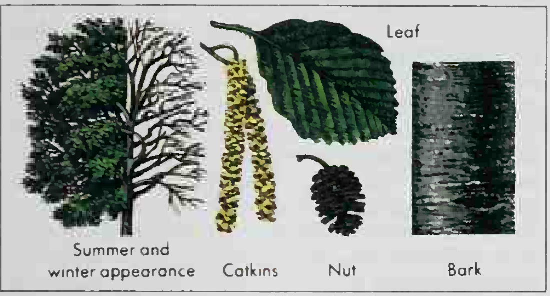
Ruth, Amy. *Louisa May Alcott.* Lerner, 1999. Younger readers.

Stern, Madeline B. *Louisa May Alcott.* 1950. Reprint. Northeastern Univ. Pr., 1999.

Alden, *AWL duhn,* **John and Priscilla,** came to America on the *Mayflower* in 1620. They became husband and wife, probably in 1622. They were among the first *Mayflower* passengers to be married in America. The Aldens had 11 children. Their descendants include President John Quincy Adams and American poets Henry Wadsworth Longfellow and William Cullen Bryant. Longfellow wrote about the couple's marriage in his fictional poem *The Courtship of Miles Standish.*



John Alden (1599-1687) was a *cooper* (barrelmaker) from Harwich, in the county of Essex, England. The Pilgrims hired him to accompany them on their voyage to America. When the *Mayflower* sailed from England, Alden had not yet decided whether he would stay in America. But he eventually became one of the leaders of the Plymouth Colony. Alden served as an assistant to the governor of the colony most of the time from about 1631 until he died. He served as treasurer from 1656 to 1658. In 1634, authorities held Alden on a technical charge of murder because he had favored defending a Plymouth outpost against attack, and in the resulting fight two men were killed. However, he was acquitted. Alden was a stern, unyielding man, and he led in the persecution of Quakers and Baptists.

Priscilla Mullens Alden (1602?-1685?) was the daughter of William Mullens, one of the Pilgrims. The Mullenses were from Dorking, in the county of Surrey, England.

James Axtell

Alder, *AWL duhr,* is the name of a group of about 30 shrubs and small trees that grow in moist ground. Alders are found in temperate regions of the Northern Hemisphere. They also grow at high elevations in parts of Central and South America, Asia, and North Africa.

Alders have oval leaves with toothed edges and produce separate male and female flowers. The female flowers grow in *catkins* (clusters of stalkless flowers) that harden into scaly, woody conelike structures. The structures have nuts and are later shed by the plant.

WORLD BOOK illustration by Chris Skilton

The speckled alder has stalkless flowers called *catkins.*

Ten species of alders grow in North America. Most are large shrubs that form dense thickets. The *speckled alder* grows throughout Canada, south to Virginia, and west to North Dakota. The *red alder* is the only alder large enough for commercial timber production. It is the most important hardwood tree in the Pacific Northwest, where it grows up to 100 feet (30 meters) high. The wood of the red alder is soft and light. It is whitish when first cut and light reddish-brown when dry. It is used mostly for inexpensive furniture. Michael J. Baranski

Scientific classification. Alders belong to the birch family, Betulaceae. The scientific name for the speckled alder is *Alnus rugosa.* The red alder is *A. rubra.*

Aldridge, Ira (1807?-1867), was the first African American actor to win fame in the Western world. He was best known for his roles in the tragedies of William Shakespeare, especially Othello. Unlike other tragic actors of his day, Aldridge was also a skilled comic actor.

Ira Frederick Aldridge was born either in New York City or Senegal and raised in New York City. In 1825, he left the United States because racial prejudice limited opportunities for black actors. He went to Britain in 1826 and made his debut as Othello in London. Aldridge also toured other European countries and achieved considerable success in Germany and Russia. Aldridge became a British citizen in 1863. Stanley L. Glenn

Museum of the City of New York

Ira Aldridge

Aldrin, *AWL drihn,* **Buzz** (1930-), a United States astronaut, was the second person to set foot on the moon. He and Neil A. Armstrong landed there in the Apollo 11 lunar module on July 20, 1969. Aldrin stepped onto the moon 19 minutes after Armstrong.

Aldrin was born in Montclair, New Jersey, on Jan. 20, 1930, and was named Edwin Eugene Aldrin, Jr. His family nicknamed him Buzz, short for Buzzer, his young sister's pronunciation of the word *brother.* He legally changed his name to Buzz Aldrin as an adult.

Aldrin graduated from the U.S. Military Academy in 1951 and became an Air Force officer. After completing pilot training in 1952, he flew 66 combat missions in the Korean War. In 1963, he received a doctor's degree in astronautics from the Massachusetts Institute of Technology. He became an astronaut later that year.

Aldrin piloted the Gemini 12 space flight in 1966. During this flight, he left the spacecraft and "walked" in space. He was partially or completely outside the spacecraft for $5\frac{1}{2}$ hours. This experience helped prove that people can work outside an orbiting vehicle.

In 1971, Aldrin resigned from the astronaut program and returned to active duty with the Air Force. He retired from the Air Force in 1972. Lillian D. Kozloski

Aleatory music, *AY lee uh TAWR ee,* is a type of music in which the composer does not determine the specific shape of a composition. The composer does not specify pitches, rhythms, and tone colors. He or she only gives ranges of these materials and relies on chance procedures or performers to select and shape them.

There are two basic types of aleatory music. In the first type, the composer uses chance procedures, such as the tossing of dice, to determine the order and quality of sounds. After the chance operations have established the musical details, the composer creates a fixed score using traditional musical notation. In the second type, the performer largely creates a composition. The composer might specify eight measures to be played with high notes, followed by six measures of low notes. The performers then create melodies, harmonies, and rhythms of their own design.

The most important composer of aleatory music is John Cage of the United States. Other important composers include Earle Brown, Morton Feldman, and Christian Wolff of the United States; Pierre Boulez of France; and Karlheinz Stockhausen of Germany.

Aleichem, Sholem. See Sholem Aleichem.

Aleixandre, *AH layks AHN dray,* **Vicente** (1898-1984), a Spanish poet, won the 1977 Nobel Prize for literature. He influenced other Spanish poets for much of the 1900's.

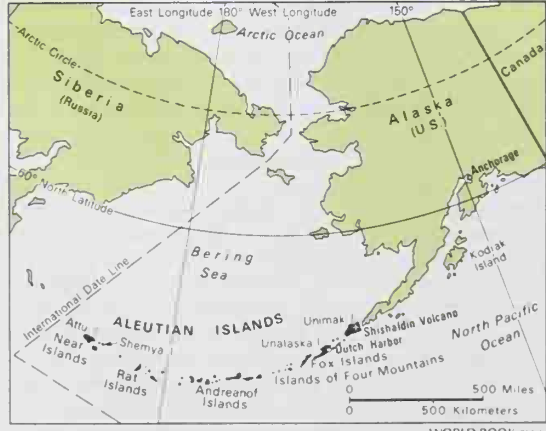
Aleixandre's early poetry, which he wrote chiefly in free verse, is highly surrealistic. It also praises the beauty of nature by using symbols that represent the earth and the sea. Many of Aleixandre's early poems are filled with sadness. These poems reflect his feeling that people have lost the passion and free spirit that he saw in nature. Aleixandre's early poetry collections include *Pas-*

sion of the Earth (1935) and *Destruction or Love* (1933).

In *Shadow of Paradise* (1944), Aleixandre began to concentrate on such themes as fellowship, friendliness, and spiritual unity. His later books of poetry include *History of the Heart* (1954) and *In a Vast Dominion* (1962).

Aleixandre was born on April 26, 1898, in Seville. He studied law at the University of Madrid. Selections of his work were translated into English in *Twenty Poems of Vicente Aleixandre* (1977). Dick Gerdes

Aleppo, *uh LEHP oh* (pop. 1,583,000), is one of the largest and most important cities in Syria. An industrial center, it lies nestled among the hills in northwestern Syria. For location, see **Syria** (map).



Aleppo is one of the oldest continuously inhabited cities in the world, dating to about 2000 B.C. The city's bazaar, narrow streets, and limestone buildings reflect its ancient past. A medieval *citadel* (fort) surrounds the city. Aleppo is one of Syria's most important agricultural and industrial centers. Its chief products include cotton, wool, and textiles. The city is home to the University of Aleppo.

In ancient times, Aleppo served as a gateway between Europe and the eastern Mediterranean to Asia. In the 1500's, the city flourished as a major trading center of the Ottoman Empire. Christine Moss Helms

Aleutian Islands, *uh LOO shuhn,* are a volcanic island chain that extends 1,100 miles (1,800 kilometers) west from the tip of the Alaska Peninsula. The Aleutians, part of Alaska, separate the Bering Sea from the Pacific Ocean. They include 14 large islands, about 55 smaller islands, and many islets. The mountains on the islands are part of the Alaska Range.

The Aleutians cover an area of 6,777 square miles (17,552 square kilometers). They lie 800 to 1,000 miles (1,300 to 1,600 kilometers) south of the Arctic Circle between the 51st and 55th parallels. This places the islands in the same latitude as England.

The Aleutians have many hot springs, as well as many cool springs and swift streams, on some of the islands. No trees grow there, but the islands have many varieties of small shrubs, flowers, grasses, and mosses. The climate is cool and foggy. The principal industry is fishing. A few sheep ranches are operated there. The population of the islands is about 8,200.

Location of the Aleutian Islands

The Aleutian Islands are divided into five main groups from east to west. These include the Fox Islands, Islands of Four Mountains, Andreanof Islands, the Rat Islands, and the Near Islands. Unimak, largest of the Aleutian Islands, has the highest mountain in the chain, Shishaldin Volcano (9,373 feet, or 2,857 meters). The village of Unalaska, on the island of the same name, is the trading center of the Aleutians and one of the leading fishing ports in the United States. Unalaska is the second largest island in the chain. It is the site of Dutch Harbor, which served as a United States naval air base during World War II (1939-1945). Claus-M. Naske

See also **Alaska** (physical map); **Aleuts**.

Aleuts, *AL ee ootz* or *uh LOOTZ,* are people who have traditionally lived on the harsh, windswept Aleutian Islands, which lie off the mainland of Alaska. The Aleuts call themselves *Unangan,* meaning *we the people.* They descended from Inuit (also called Eskimos) who settled on the islands thousands of years ago. But the Aleut language differs from that of the Inuit.

The early Aleuts lived off the rich sea environment. Aleut hunters harpooned whales, seals, and other sea mammals from seagoing kayaks. They caught fish with spears and on fishhooks and also hunted birds. The Aleuts wore parkas made of furs, bird skins, or other parts of animals. Several Aleut families lived together in large homes sunk 3 to 4 feet (91 to 122 centimeters) into the ground. The frames consisted of drift logs or whale bones. The homes were covered with a layer of dry grass or skins and a layer of sod.

Russian explorers discovered the Aleutian Islands in 1741. Russian traders and fur hunters later practically enslaved the Aleuts and killed many of them. Many other Aleuts died from diseases brought by the Russians. The Aleut population once numbered between 12,000 and 15,000 people. But by the mid-1800's less than 2,000 remained.

In 1867, the United States bought the islands, along with the rest of Alaska. Japanese forces attacked the islands during World War II (1939-1945). They captured the Aleut villagers of Attu and later sent them to a prison camp in Japan. There, about half the Aleuts died of tuberculosis and malnutrition. The United States government evacuated other Aleuts to Alaska. The Aleuts returned to the islands in 1945.

In 1971, the United States Congress passed the Alaska Native Claims Settlement Act, and the Aleuts regained control of much of their homeland. There are about 12,000 Aleuts living in Alaska. They follow a modern way of life, but many still hunt and fish for food.

Alewife is a fish that lives mainly in the Great Lakes and along the Atlantic coast of North America. It has large eyes, a forked tail, silvery sides, and a grayish-green back. Freshwater alewives grow 3 to 6 inches (8 to 15 centimeters) long. Saltwater alewives grow as long as 15 inches (38 centimeters). Saltwater species are caught commercially for human food. Freshwater species are used for animal feed and fertilizer. Saltwater alewives swim along the Atlantic coast from the Canadian province of Newfoundland and Labrador to South Carolina. They are *anadromous*—that is, they migrate to freshwa-

ter rivers to lay their eggs. Each female lays approximately 10,000 to 100,000 eggs in the spring. The adults then return immediately to the ocean. The young swim to the ocean a few months later, after they have grown.

Alewives probably are not native to any of the five Great Lakes other than Lake Ontario. They colonized the other four lakes after 1932. Sudden die-offs of alewives often occur during the spring in the Great Lakes. Scientists believe these die-offs may be due to sudden drops in water temperature.

Scientific classification. The alewife belongs to the herring family, Clupeidae. Its scientific name is *Alosa pseudoharengus.*

Henry W. Robison

Alexander I (1777-1825) was czar of Russia from 1801 to 1825. He became known for his stubborn struggle with Emperor Napoleon I of France. Russia finally defeated Napoleon after France invaded Russia in 1812. Alexander was influential at the Congress of Vienna, which in 1815 approved Russian territorial gains in Poland, Finland, and Bessarabia. The same year, he led the formation of the Holy Alliance (see **Holy Alliance**).

Alexander was kind and well-intentioned. At the beginning of his reign, he considered freeing Russia's serfs, introducing a constitution, and limiting the czars' powers. But Alexander was also weak, and nothing came of these projects. Disappointed liberal army officers tried unsuccessfully to overthrow the government soon after Alexander died. Joseph T. Fuhrmann

See also **Russia** (Alexander I); **Vienna, Congress of.**

Alexander I (1888-1934) became king in 1921 of the Kingdom of the Serbs, Croats, and Slovenes, later called Yugoslavia. This country had been created in 1918 as the homeland of several closely related peoples. From 1918 to 1921, Alexander ruled as regent for his father, King Peter I. Alexander, a Serb, believed the Serbs should rule the new country. But the other peoples opposed Serb domination. As a result, Alexander made himself dictator in 1929. That same year, he renamed the country Yugoslavia. In 1934, he was assassinated by a Macedonian from Bulgaria who was supported by Croatian revolutionaries. Alexander was born in Cetinje, Montenegro. See also **Peter II.** R. V. Burks

Alexander II (1818-1881) was czar of Russia from 1855 to 1881. He succeeded his father, Nicholas I. Alexander is called the "czar liberator" because he freed Russia's serfs in 1861. He also introduced local self-government and a court system based on French models. He modernized the Russian army and defeated the Turks in 1878 (see **Russo-Turkish wars**). He was assassinated in 1881 by revolutionaries who thought he was too conservative. See also **Russia** (Alexander II). Joseph T. Fuhrmann

Alexander III (1105-1181) was elected pope in 1159. The Holy Roman Emperor Frederick I supported an antipope, Victor IV, who had been elected by a minority of the cardinals. The split between the emperor and papacy caused a division within the papacy that resulted in the election of four antipopes during Alexander's reign. During the split, Alexander spent long periods away from Rome because the emperor made it impossible for him to reside there. Alexander allied himself with the city-states of northern Italy, which formed the Lombard League to resist imperial authority. After a long war, the league defeated Frederick at the Battle of Legnano in 1176. Frederick was forced to make peace with the papacy and finally recognized Alexander as pope in 1177.

In 1179, Alexander held a church council called the Third Lateran Council. He issued a number of important decrees, including a requirement that future popes be elected by two-thirds of the cardinals.

Alexander was born in Siena, Italy. His given and family name was Rolando Bandinelli. Kenneth Pennington

Alexander III (1845-1894) was czar of Russia from 1881 to 1894. He became czar after his father, Alexander II, was assassinated by revolutionaries. Alexander II had adopted a number of liberal reforms. Alexander III opposed further reform and energetically fought the revolutionaries. During his reign, Russian industry and science made impressive gains, and culture thrived. See also **Russia** (Alexander III). Joseph T. Fuhrmann

Alexander VI (1431-1503) was the most worldly of the Renaissance popes. He was elected pope in 1492 and displayed the character and ambition more typical of a *secular* (nonreligious) ruler.

Alexander was born in Játiva, Spain. His given and family name was Rodrigo Borja (Borgia in Italian). For many years, he held the profitable position of vice chancellor of the Roman Curia, accumulating vast wealth and influence. He fathered many children, whose fortunes he worked to advance even before becoming pope.

The first years of Alexander's reign were dominated by Italian wars, which broke out when King Charles VIII of France invaded Italy in 1494. The pope managed to survive the dangers of the conflict, largely through skillful diplomatic maneuvers. After Alexander's son Juan was murdered in Rome in 1497, the grief-stricken pope decided to launch a program of church reform. But he never carried it out. For the rest of his reign, Alexander devoted much of the papacy's resources to furthering the ruthless ambitions of his son Cesare to control central Italy for the Borgias. Charles L. Stinger

See also **Borgia, Cesare; Borgia, Lucrezia; Savonarola, Girolamo.**

Alexander, Grover Cleveland (1887-1950), was one of baseball's greatest pitchers. He won 373 games and pitched 90 shutouts while playing for the Philadelphia Phillies, Chicago Cubs, and St. Louis Cardinals from 1911 through 1930. Alexander set a record in 1916 by pitching 16 shutouts for the Phillies. He won two games in the St. Louis Cardinals' 1926 World Series victory over the New York Yankees. Alexander was born in Elba, Nebr. He was elected to the National Baseball Hall of Fame in 1938.

Dave Nightingale

Alexander, Lloyd (1924-), an American author, won the 1969 Newbery Medal for his story *The High King* (1968). The book was the fifth in Alexander's series

of fantasies about Prydain, an imaginary kingdom in Wales. He became interested in Wales and its legends while stationed there in 1943 during World War II. His Westmark trilogy (1981-1984) and Vesper Holly books (beginning in 1986) are adventure-fantasy series for young adults. Alexander's interests in cats, music, and mythology often appear in the plots of his stories. He was born on Jan. 30, 1924, in Philadelphia.

Kathryn Pierson Jennings

Alexander of Battenberg. See Battenberg.

Alexander of Tunis, Earl (1891-1969), was a British military leader and statesman and the last British-born governor general of Canada. He was one of the main Allied battle commanders during World War II (1939-1945). Alexander served as governor general of Canada from 1946 to 1952. He traveled extensively in the country and was highly popular. During his term, in 1949, Newfoundland (now Newfoundland and Labrador) became Canada's 10th province.

Harold Rupert Leofric George Alexander was born on Dec. 10, 1891, in London. In 1911, he became an officer in the Irish Guards of the British Army and later commanded a battalion in France during World War I (1914-1918).

During World War II, Alexander organized the evacuation of Allied troops at Dunkerque, France, in 1940. Later, he served as British commander in Burma (now Myanmar), the Middle East, and North Africa. Alexander directed the Allied campaigns in Sicily and Italy in 1943 and 1944. In 1944, he was named supreme commander of the Allied forces in the Mediterranean area. The same year, Alexander became the youngest field marshal in the British Commonwealth. He was made a viscount in 1946 and an earl in 1952. Alexander was Britain's minister of defense from 1952 to 1954. Jacques Monet

Alexander the Great (356-323 B.C.) was king of the Macedonians and one of the greatest generals in history. He conquered the Persian Empire, which stretched from the Mediterranean Sea to India and formed much of what was then considered the civilized world. Alexander's conquests furthered the spread of Greek ideas and customs in western Asia and Egypt. He thus made possible the rich culture of the Hellenistic Age.

His youth. Alexander was born in Pella, the capital of the Macedonian kingdom. His father was Philip II, the shrewd king and general who conquered Greece. His mother was Olympias, a brilliant and hot-tempered princess from Epirus in western Greece. Olympias told Alexander that his ancestor was the hero Achilles. Throughout his life, Alexander carried with him a copy of the great poem the *Iliad,* which told of the deeds of Achilles (see **Iliad**). Philip taught Alexander that the Macedonian kings were descended from the hero Hercules (also called Heracles), who in Greek mythology was a son of the god Zeus.

Roman copy of marble sculpture after Lysippus, Capitolino Museum, Rome (Alinari from Art Reference Bureau)

Alexander the Great

There are many stories about Alexander's life. Some are true, but others are legends. According to one story, the boy Alexander tamed the great horse Bucephalus. This magnificent steed later carried Alexander as far as India, where it died. Alexander built a city there and named it Bucephala after the horse.

In 343 or 342 B.C., Philip hired the great philosopher Aristotle to tutor Alexander. Aristotle may have encouraged Alexander's interest in other countries and peoples, as well as his curiosity about plants and animals.

Alexander's education followed the Greek principle of "a sound mind in a sound body." He studied literature, philosophy, and politics, and he also received training in sports, physical fitness, and warfare. Alexander's official schooling ended abruptly at the age of 16, when his father called him away for duties in the government.

In 338 B.C., the 18-year-old Alexander commanded the cavalry in Philip's army in the Battle of Chaeronea. This battle brought Greece under Macedonian control. Philip next prepared to invade the Persian Empire in Asia. But before he could do so, Philip was murdered by one of his bodyguards. Thus, at the age of 20, Alexander became king of the Macedonians. After Philip's death, some Greek cities under Macedonian rule revolted. In 335 B.C., Alexander's army stormed the walls of the rebellious city of Thebes and demolished the city. About 30,000 inhabitants of the city were sold into slavery.

Invasion of Asia. With Greece under control, Alexander turned to his father's plan for attacking the Persian Empire. In 334 B.C., he led an army of about 35,000 infantry and cavalry across the Hellespont from Europe to Asia. The Persians sent out troops that met Alexander's forces at the Granicus River. Alexander and his cavalry charged across the river and won the battle. This victory opened Asia Minor to Alexander.

After marching along the southern coast of Asia Minor, Alexander and his army headed north to the city of Gordium. There, according to legend, Alexander found a wagon with an ox yoke tied by a tight, complex knot. An ancient prophecy said that whoever could untie this *Gordian knot* would become ruler of Asia. According to the most famous version of the story, Alexander first tried unsuccessfully to untie the knot and then drew his sword and cut it in a single stroke.

By 333 B.C., Alexander had reached the coast of Syria. There, in a fierce battle at Issus, he defeated the king of Persia, Darius III, but could not capture him. Alexander's army then marched south into Phoenicia to capture key naval bases at port cities. Part of one such city, Tyre, was on an island about $\frac{1}{2}$ mile (800 meters) offshore. Unable to capture the island from the sea, Alexander had his engineers build a causeway out to the island, converting it into a peninsula that remains even today. His troops used battering rams, catapults, and mobile towers in their attack. The Tyrians surrendered in 332 B.C., after seven months of fighting. Alexander's use of huge siege machines at Tyre led to a new age of warfare.

Alexander next entered Egypt. The Egyptians welcomed him as a liberator from Persian rule, and they crowned him pharaoh. On the western edge of the Nile Delta, Alexander founded a city in 331 B.C. and named it Alexandria after himself.

From Alexandria, the Macedonian king made a long, difficult trek through the Libyan Desert, a part of the

Alexander's empire extended from Greece to India, with Babylon as its capital. In 323 B.C., when Alexander died, his empire covered much of what was then considered the civilized world. Alexander's conquests helped Greek culture spread in Egypt and western Asia.

WORLD BOOK map

Sahara, to the oasis of Siwah. He consulted the oracle of the god Zeus-Ammon, and, according to legend, the oracle pronounced Alexander the son of the god.

Victory over Darius. Alexander left Egypt in 331 B.C., traveling eastward into the Persian Empire. King Darius had formed a huge army that met Alexander's forces on a vast plain between the villages of Gaugamela and Arbela, just east of the Tigris River. The Persians far outnumbered Alexander's army, but Alexander's tactics and the training of his troops proved superior in battle. Darius was forced to flee, and he escaped across the Zagros Mountains into Media. This clash of armies, known as the Battle of Gaugamela or the Battle of Arbela, ended more than two centuries of Persian rule in Asia.

Alexander easily captured the fabled city of Babylon and then the Persian capital at Susa. In the winter of 331-330 B.C., Alexander's army marched to Persepolis. There he seized the royal palaces and captured a vast storehouse of gold and silver. Before leaving Persepolis, Alexander had his soldiers burn down the palaces.

In the spring of 330 B.C., Alexander swung north toward the Caspian Sea to find Darius. The Persian king could not gather enough troops to fight Alexander, and he was killed by his own nobles. The death of Darius left Alexander king of Asia.

Central Asia and the Indus. Alexander moved his army into Bactria and then across the Hindu Kush mountains into Sogdiana, overcoming local military challenges as he went. In 327 B.C., Alexander married the Bactrian princess Roxane.

By 326 B.C., Alexander's forces had reached the upper Indus River Valley, in what is now Pakistan. Alexander wanted to continue east toward the Ganges River. But his homesick troops were tired of traveling and refused to follow him any farther eastward.

During his years in central Asia, Alexander began to adopt the customs of the Persian kings. Many of his troops resented this change. They considered their king a fellow warrior, not a godlike sovereign. Plots against Alexander's life appeared, and he executed several prominent Greeks and Macedonians who he believed had conspired against him. In a drunken brawl, Alexander killed his good friend Cleitus, who had saved his life at Granicus.

Return westward. In 325 B.C., Alexander had ships built, and part of his army sailed westward from the mouth of the Indus River. These troops explored the northern shore of the Arabian Sea and the Persian Gulf. Alexander led the rest of his troops west across the Desert of Gedrosia. As many as half of his forces died on the way—more soldiers than enemy armies had killed.

Upon his return to Babylon, Alexander became busy with the administration of his vast domain, which stretched from Greece to the Indus. He probably intended to make Babylon his capital. Alexander planned new expeditions to northern Africa and Arabia. He tried to encourage trade and commerce and to develop a greater spirit of cooperation between Macedonians and Persians. He married a Persian princess who was a daughter of Darius, and he performed a mass marriage ceremony joining thousands of his soldiers to Persian women. Alexander also tried to incorporate large numbers of Persians into his army. But he failed to establish a stable kingship to maintain what he had won.

His death. In the spring of 323 B.C., Alexander became seriously ill with a fever at Babylon. He also suffered from exhaustion and the effects of several battle wounds. He died at the age of 32 on June 10, 323 B.C. His body was placed in a glass coffin in a special tomb at Alexandria.

After Alexander died, his half-brother, Philip III Arrhidaeus, became king of Macedonia. At the time of Alexander's death, Roxane was pregnant with his son, Alexander IV, who later shared rule over the Macedonians with Philip. But Philip was murdered in 317 B.C., and young Alexander was killed about seven years later.

No one succeeded Alexander the Great in the rule of his vast empire. His leading generals became governors of various areas and fought among themselves for control of the empire. By 300 B.C., Alexander's empire had split into a number of independent states. The three most powerful states were led by Alexander's generals Antigonus, Ptolemy, and Seleucus. Eugene N. Borza

Alexandria (pop. 3,380,000) is Egypt's busiest seaport and second largest city. Only Cairo, Egypt's capital, has more people. Alexandria is also a major industrial center. The city lies on Egypt's Mediterranean coast in the northwest corner of the Nile Delta, a fertile agricultural area. For location, see Egypt (political map). In ancient times, Alexandria was one of the world's most important commercial and cultural centers.

The city is built on a long *isthmus* (strip of land) between Lake Maryut and the Mediterranean Sea. A hammer-shaped peninsula extends out from the isthmus and forms two large harbors, east and west. These magnificent harbors have made Alexandria one of the Mediterranean's leading ports for thousands of years.

Hotels and beaches line the Corniche, a broad, curving road along the city's shoreline. The city is the home of Alexandria University. The Bibliotheca Alexandrina, a large research library scheduled to open in 2002, is a revival of Alexandria's great ancient library.

People. Almost all of Alexandria's people are Egyptians. Most of the Egyptians are Muslims who speak Arabic. A small number of foreigners live in the city.

In general, Alexandria's upper- and middle-class residents live in the east part of the city. Most working-class people live on the west side close to industrial areas, and on the peninsula between the two harbors. Most residents live in large apartment complexes.

Economy. Manufacturing plants in or near the city produce petroleum products, plastics, processed foods, steel, textiles, and other goods. Tourism also contributes to the city's economy. Huge numbers of vacationers come to Alexandria each summer to take advantage of the city's beaches and resorts.

History. Alexandria is named after Alexander the Great, the king of Macedonia, who founded the city in 331 B.C. after conquering Egypt. After Alexander died in 323 B.C., one of his generals, Ptolemy, took over Egypt's government and founded the dynasty known as the Ptolemies. Ptolemy made Alexandria the capital of Egypt.

Under the reign of the Ptolemies, Alexandria thrived. It was one of the great centers of trade and culture, and its population was the largest of any Mediterranean city. Many of the leading thinkers of the Greek-speaking world worked in the city. The towering Lighthouse of Alexandria was one of the Seven Wonders of the Ancient World (see Seven Wonders of the Ancient World [with picture]). The city had a scientific institute called the Mouseion and a library with about 500,000 scrolls made of an early form of paper called *papyrus.* These institutions conserved and developed the science, literature, philosophy, and religious culture of the ancient world.

The Ptolemaic dynasty ended when its last ruler, Cleopatra, rebelled against the growing power of Rome. After her failure to defend Egypt's independence, she killed herself in 30 B.C. Egypt was then made part of the Roman Empire. Under the Romans, Alexandria remained an important trade center. It also was a major center for the processing of gold and silver and the production of glass, jewelry, linen, and papyrus.

According to tradition, Saint Mark, a Christian missionary, founded the Egyptian (Coptic) church in Alexandria around A.D. 40. The city, which already had a large community of Jews, soon also developed a thriving Christian community. Bishops of Alexandria exercised enormous influence in defining beliefs and practices of the new Christian faith.

During Roman rule, clashes often took place between rival ethnic and religious groups in the city. In the late 200's, the Mouseion and library were destroyed during a war over control of the Roman Empire. When the Roman Empire was divided in 395, Egypt became part of the Byzantine Empire.

In 642, Arab Muslims conquered Egypt. The Arabs moved the capital from Alexandria to what is now Cairo. Alexandria's population gradually declined, and the city ceased to be a cultural center. In 1517, Egypt became part of the Ottoman Empire. Under Ottoman rule, Alexandria's population fell sharply.

In 1805, an Ottoman army officer named Muhammad Ali was appointed governor of Egypt. Under Muhammad Ali and his successors, Alexandria again grew to be a center of business, banking, and trade. In 1820, a canal connecting Alexandria to the Nile River was completed. A railroad linking Alexandria to Cairo was built in the 1850's.

The city's population grew rapidly in the 1800's. Most of the new residents were Egyptian Muslims. But large numbers of immigrants from other countries also came to the city. Many of these foreigners became important business leaders. Tensions rose between the city's Egyptian and foreign communities, and bloody riots took place in 1882. Later that year, British warships bombarded the city, and British troops occupied Egypt. The British acted to crush a movement for Egyptian self-government, protect foreigners, and further British influence in the region. Foreign business interests strengthened their control of Alexandria in the late 1800's and early 1900's.

After Egypt gained independence from the United Kingdom in 1922, foreign control over the city weakened. By the 1950's, most foreigners had left Alexandria. During the 1950's and 1960's, rapid industrial development took place in the city.

In the 1990's, archaeologists working in waters near Alexandria found hundreds of granite blocks, huge statues, and other stonework belonging to the ancient lighthouse, which had collapsed during an earthquake in the 1300's. The archaeologists also found about 40 sunken ships, which showed the wide range of Alexandria's early commercial activity. Michael J. Reimer

Alexandria, Virginia (pop. 128,283), is a historic city on the west bank of the Potomac River, across from Washington, D.C. For the location, see Virginia (political map). During the 1730's, a warehouse was established on the site of Alexandria for the export of tobacco, Virginia's chief cash crop. The military leaders George Washington, Henry "Light-Horse Harry" Lee, and Robert E. Lee,

who was Henry Lee's son, had homes in Alexandria. Their homes are preserved in a historic district that has made Alexandria a major tourist center. At Gadsby's Tavern, Washington recruited his first command in 1754 and held his last military review in 1799. *The Alexandria Gazette Packet,* founded in 1784, is one of the oldest newspapers in the United States.

Alexandria was part of the District of Columbia from 1791 to 1846. Today, it is a suburb of Washington, D.C. Alexandria has more than 150 technology and research and development firms and a large freight yard that serves three railroads. It is also the home of more than 250 national trade and professional associations. It has a council-manager form of government.

Susan L. Woodward

Alexandrite, *AL ihg ZAN dryt,* is a rare gem that has a high luster. It is a variety of a mineral called chrysoberyl. Alexandrites are dark green in natural light but appear red in most kinds of artificial light. Jewelers cut and polish alexandrites so that they have numerous flat surfaces called *facets.* Faceted alexandrites are used to create earrings, necklaces, rings, and other forms of jewelry. The alexandrite is one of the birthstones for the month of June.

Alexandrites were first discovered in the Ural Mountains in Russia in 1833. The stone was named after Alexander II, who later became the czar of Russia. Today, alexandrites are still mined in Russia. Other countries that produce alexandrites include Brazil, Myanmar, Sri Lanka, Zambia, and Zimbabwe. Pansy D. Kraus

Alexia. See Aphasia.

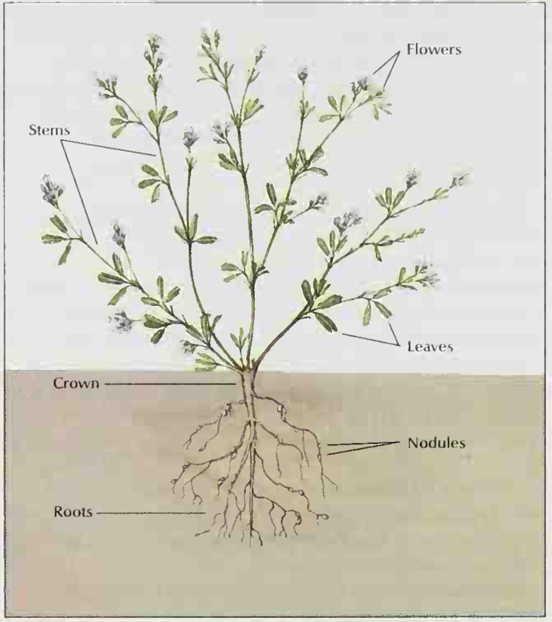
Alfalfa is a valuable crop that is grown mainly for *forage* (livestock feed). It is sometimes called the "queen of the forages." It promotes rapid growth and good health in the animals, especially cattle and sheep. The alfalfa plant contains large amounts of minerals, proteins, and vitamins, and farmers use it in order to make hay, meal, and silage. They also grow alfalfa for pasture, for its seeds, and to enrich the soil and protect it from erosion. Some people grow alfalfa indoors and eat the plant's sprouted seeds. These seeds are known as *alfalfa sprouts.* Alfalfa is also known as *lucerne* throughout most of the world.

The most important alfalfa-growing regions include North and South America, Australia, and parts of southern and eastern Europe. The United States raises about 80 million tons (73 million metric tons) of alfalfa annually. California, South Dakota, Wisconsin, and Minnesota are the leading alfalfa-growing states in the United States. In Canada, the leading alfalfa-growing province is Alberta. Other leading alfalfa-growing provinces are Ontario and Saskatchewan.

The alfalfa plant

Alfalfa is a *perennial*—that is, it grows from year to year without being replanted. In humid regions, alfalfa plants live from 5 to 7 years. In dry regions, they live 10 years and sometimes longer.

The alfalfa plant is a *legume,* a member of the pea family. It bears seed pods, in which four to eight seeds develop. The plant has many slender stems. They grow about 3 feet (0.9 meter) high and bear compound leaves, each consisting of three leaflets. New stems grow from buds on the plant's woody *crown* (base), which is between the stems and the roots. The stems mature in about six weeks. They grow straight up in some types of alfalfa and almost parallel to the ground in others. The leaves and stems of the alfalfa plant are used for livestock feed.



Flowers grow on the stems in clusters called *racemes.* Each raceme consists of 5 to 50 flowers. Most alfalfa

J. C. Allen and Son

Fields of alfalfa are harvested as the plants begin to flower. The leaves and stems of the alfalfa plant contain large amounts of minerals, proteins, and vitamins. Farmers grow alfalfa mainly for livestock feed.

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd.

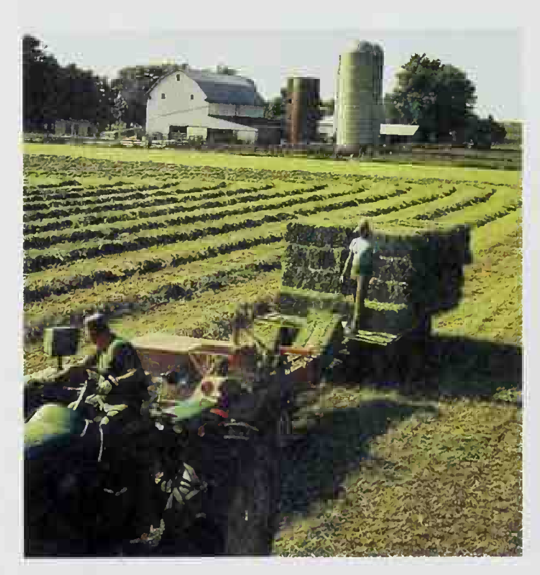
The alfalfa plant has many slender stems, which develop from buds on the *crown* (base). Swellings called *nodules* grow on the roots. Bacteria in the nodules take nitrogen from the air. Nitrogen is essential to the plant's health and growth.

flowers are purple, but some are green, white, yellow, or *variegated* (multicolored).

Most of the roots of the alfalfa plant grow in the upper foot (0.3 meter) of soil. But in fertile, well-drained soils, some alfalfa roots extend as deep as 15 feet (4.6 meters) or more. These deep roots can obtain water that lies far belowground. Because of their deep roots, alfalfa plants have a greater resistance to drought than do many other crops.

Uses of alfalfa

As livestock feed. Cattle graze on some alfalfa, but farmers process most of the crop into hay, silage, or meal. All these forms of the feed can be stored. Farmers often plant alfalfa mixed with a grass for grazing. They let their cattle graze for about a week. Then they keep the animals away for four weeks or longer until the alfalfa plants grow back. This method of feeding livestock is called *rotational grazing.*



In the United States, farmers harvest alfalfa mainly for use as hay. Some hay is stored in rectangular bales, usually weighing from 50 to 150 pounds (23 to 68 kilograms). Round bales, weighing as much as 2,000 pounds (910 kilograms), are also used to store hay.

To make hay, farmers cut the alfalfa and let the sun dry the plants in the field. At the time alfalfa is cut, it contains 70 to 80 percent moisture. Before being baled as hay, the plants should contain about 15 percent moisture. Hay that is too dry when it is baled will lose its leaves. If the leaves, which contain many nutrients, fall off, the hay loses much of its food value. If baled hay contains too much moisture, it spoils and cannot be fed to livestock.

Baled hay is widely used for cattle, sheep, and horses. Farmers prepare hay to feed their own animals or produce it as a cash crop for sale to other livestock raisers. See Hay.

Some alfalfa hay is stored in the form of thickly packed 1-inch (2.5-centimeter) cubes. Large cubing machines make these alfalfa cubes, and the process is expensive. However, cubed hay can be transported over long distances more economically than baled hay.

Some alfalfa plants are chopped and then stored as

J. C. Allen and Son

Dehydrating alfalfa. To dehydrate alfalfa for use as hay, farmers cut the alfalfa and let the sun dry it in the field. The hay is then pressed into bales, *left.* Most alfalfa meal is made by drying cut alfalfa at a high temperature in a dehydrator, *right,* and then pressing it into pellets.

silage. Silage is a higher-quality feed than hay, and it works better than baled or loose hay in automatic feeding systems. Hay must remain in the field to dry longer than silage and so may be exposed to damp or wet weather. Such weather may cause freshly cut alfalfa to mold and lose much of its food value. As a result, silage retains many nutrients that hay may lose. See **Silo**.

Most alfalfa meal is made by drying alfalfa at a high temperature in a dehydrator and then grinding it and pressing it into pellets. The pellets may be stored or sold. Farmers give alfalfa meal directly to their livestock or use it in preparing mixed feeds. Poultry farmers often add alfalfa meal to poultry feed because it helps produce high-quality eggs and chickens.

As a cover crop. Many farmers use alfalfa as a *cover crop*—that is, to enrich the soil and protect it from erosion. Alfalfa plants enrich the soil by adding more nitrogen to the soil than they use for growth (see Nitrogen [Nitrogen and life]). Bacteria that live in *nodules* (swellings) on alfalfa roots take nitrogen from the air for the plant's growth and health. Alfalfa uses the nitrogen, which later becomes part of the soil as the plants die and decay. Farmers often rotate alfalfa crops with small grain crops that use the nitrogen left in the soil by alfalfa. Alfalfa, especially when mixed with a grass, will hold the soil in place and thus help prevent soil erosion.

As a seed crop. Some farmers grow alfalfa chiefly to obtain large quantities of the seeds. They sell the seeds to other farmers who raise alfalfa for livestock feed.

Alfalfa plants cultivated for seed require sunny days and cool nights for successful growth, and dry weather for harvesting. Alfalfa seed producers must also keep bees to pollinate the plants' flowers, since the seeds develop only if the flowers have been pollinated. The leading alfalfa seed-producing states of the United States are California, Washington, and Idaho, in that order.

Kinds of alfalfa

Most types of alfalfa plants grown in the United States originated from seeds brought by European immigrants. Farmers created many new varieties by planting seeds from the alfalfa plants that grew in their fields. These plants, called *Common* alfalfas, were identified by the state where they were developed. For example, *Kansas Common* was an important early variety of alfalfa plant.

New varieties of alfalfa are continually being developed by plant breeders. Alfalfas are classified into three main groups—*hardy, medium hardy,* and *nonhardy*—according to how they withstand winter weather. Hardy alfalfas can survive severe winter weather and are grown chiefly in regions where such weather occurs. Medium hardy alfalfas are raised mainly in places that have less harsh winters. The nonhardy alfalfas come from regions with mild winters.

Hardy alfalfas grow primarily in the northern part of the United States and in Canada. These plants grow the most in spring and early summer. Little or no growth occurs in fall, even in mild climates. Some hardy alfalfas were developed from seeds brought from Russia, Turkey, and other countries that have regions with cold climates.

Medium hardy alfalfas are raised mainly in the central United States. Some hardy alfalfas are also grown in this region. The two types cannot be distinguished in spring and early summer, but medium hardy alfalfas grow more during the fall.

Nonhardy alfalfas thrive on irrigated land in the Southern and Southwestern United States, chiefly in Arizona, California, Nevada, and New Mexico. In colder climates, such alfalfas grow during the fall until frost kills the stems and leaves. They cannot survive cold winters. Many nonhardy alfalfas were developed from seeds brought from Peru and such northern African countries as Egypt, Libya, and Tunisia.

Growing alfalfa

Cultivating, planting, and harvesting. Alfalfa plants flourish in fertile, well-drained soil that is neutral or slightly alkaline (see **Soil** [Chemical conditions]). In arid areas, alfalfa needs irrigation for successful growth. Before planting alfalfa, many farmers enrich the soil with fertilizers and add *herbicides* (weed-killing chemicals). They plow the soil and then plant alfalfa seeds $\frac{1}{4}$ to $\frac{1}{2}$ inch (6 to 13 millimeters) or less below the surface.

Most farmers plant alfalfa in early spring or late summer. They harvest a new crop every four to six weeks. The harvests must be timed so that the alfalfa is cut after the plants begin to produce flower buds, but before the seed pods form. If alfalfa is cut before the bud stage, the next crop will be smaller than normal. Frequent cutting before the bud stage also kills the plants. Farmers harvest alfalfa before the seed pods form because the nutritional value of the plants begins to decline after they bear seeds.

Diseases and pests. A number of diseases and pests damage alfalfa crops. The diseases include *anthracnose, bacterial wilt, crown rot, root rot, leaf spot,* and *spring blackstem.* All of these diseases are caused by bacteria or fungi.

Anthracnose destroys the base of alfalfa stems, and bacterial wilt slows the growth of the plants (see **Wilt**). Both these diseases can kill alfalfa plants. Crown rot and root rot severely damage alfalfa that has been injured by cold weather, insects, or poor harvesting methods (see Rot). Leaf spot and spring blackstem reduce the quality and the quantity of alfalfa crops by causing the leaves of the plants to drop off.

Scientists have developed varieties of alfalfa that resist anthracnose, bacterial wilt, and leaf spot, but other diseases that attack the plant remain uncontrolled. Farmers often practice crop rotation to reduce losses of alfalfa plants to disease. In this method, a crop other than alfalfa is grown in a field for one to three years before alfalfa is planted. During the years that alfalfa is not grown in the field, pests that thrive on the plant are deprived of their primary food source. As a result, the pest populations decline and alfalfa can be safely planted in the field. See **Cropping system**.

Pests that attack alfalfa include such insects as alfalfa weevils, potato leafhoppers, and aphids. Some *nematodes* (roundworms) and weeds also damage alfalfa.

Young alfalfa weevils eat alfalfa leaves, reducing the yield and quality of the hay (see **Weevil**). Potato leafhoppers and aphids restrict the growth of the plants by sucking juices from alfalfa stems. Stem nematodes and root knot nematodes live as parasites in alfalfa stems and roots. They cause the plants to grow slowly, and, in some cases, to die. Weeds use up food and water that

alfalfa plants need, and so the alfalfa yield is reduced. Farmers use insecticides to control alfalfa weevils and potato leafhoppers, and researchers have developed alfalfas that resist aphids, root knot nematodes, and stem nematodes. Herbicides are used to control weeds.

History

Alfalfa is the only crop used for forage that has been cultivated since prehistoric times. It probably originated in the Middle East. Records on brick tablets found in Turkey indicate that alfalfa was an important cattle feed crop in that region about 1400 B.C. It was brought to Greece by 490 B.C. and later to northern Africa and the regions that include present-day Italy and Spain. Today, alfalfa grows wild in parts of Africa, Asia, and Europe.

During the A.D. 1500's, Portuguese and Spanish explorers brought alfalfa to Central and South America and to what is now the Southwest United States. Many settlers brought alfalfa from Europe to the American Colonies. However, they could not grow it in the New World because of the acidic soils along the Atlantic Coast. As a result, alfalfa did not become widely grown in the United States until after 1850. That year, an alfalfa called *Chilean clover* was brought to California from Chile. It was grown successfully in California, and farmers in other states began to raise it.

Various types of alfalfas were also brought to northern regions of the United States from cold climates in Europe and Asia. Plant breeders used seeds of these alfalfas to develop the many varieties now cultivated in the United States.

Scientific classification. Alfalfa belongs to the pea family, Fabaceae or Leguminosae. The scientific name for the varieties of alfalfa plants cultivated in the United States is *Medicago sativa.* Donald J. Reid

Alfalfa weevil. See Alfalfa (Diseases and pests); Weevil.

Alfieri, *ahl FYEH ree,* **Vittorio,** *veet TAWR yoh* (1749-1803), was an Italian playwright and poet. He was born into an aristocratic family in Asti, where French was the spoken language of the nobility. The experience of writing his first play in 1774 taught him how imperfectly he knew Italian. He studied Italian language and literature so he could write tragedy, a literary form long ignored by other Italians. From 1775 to 1787, Alfieri wrote 19 verse tragedies, most of which reflect his hatred of tyranny and his admiration of human dignity. These themes helped arouse a spirit of nationalism in Italy. All his plays have a mythical, Biblical, or historical plot. His best works include *Filippo* (1775), *Oreste* (1786), and *Mirra* (1786). Alfieri wrote many poems, a treatise in defense of liberty, and a lively two-part *Autobiography* (1790, 1803).
Richard H. Lansing

Alfonso XIII, *al FAHN soh* (1886-1941), served as king of Spain from 1902 until 1931, when Spain became a republic. Alfonso reigned at a time when Spaniards were dissatisfied with political *oligarchy* (rule by few), low wages, poor living conditions, and a war in Morocco. The parliamentary government was unable to solve these problems.

Alfonso XIII was born in Madrid, six months after the death of his father, King Alfonso XII. His mother, archduchess María Cristina of Austria, ruled until Alfonso came of age. In 1923, with Alfonso's approval, General Miguel Primo de Rivera led a bloodless overthrow of the constitutional government. Primo controlled the government until about 1930. By then support for the monarchy had collapsed, and a Republican government assumed power in 1931. Alfonso fled into exile, and the parliament declared him guilty of treason. The charge was dropped after a new government headed by Francisco Franco came to power in 1939. Alfonso died in Rome in 1941. In 1975, the monarchy was restored in Spain. Alfonso's grandson, Juan Carlos, became king. In 1980, Alfonso's remains were removed from Rome and reburied in the Escorial, a combination burial place, church, college, monastery, and palace near Madrid. See Juan Carlos I; Escorial. Stanley G. Payne

Alfred the Great (849-899) was king of the West Saxons in southwestern England. He saved his kingdom, Wessex, from the Danish Vikings and laid the basis for the unification of England under the West Saxon monarchy. He also led a revival of learning and literature. He was such an outstanding leader in war and peace that he is the only English king known as "the Great."

Alfred was born in Wantage, now in Oxfordshire, England. He was the youngest son of King Ethelwulf of Wessex. According to the Welsh writer Asser, who wrote a biography of Alfred shortly after his death, Alfred was always eager to learn. Asser says that Alfred's mother offered a book of Anglo-Saxon poems as a prize to the first of her sons who could read it. Alfred won. As a boy, Alfred twice went to Rome, where the pope acknowledged the status of the royal house of Wessex. The journeys also showed Alfred the contrast between England and the more advanced parts of Europe.

Alfred became king in 871 at the death of his brother Ethelred. The West Saxons had been at war with the Danes for many years. After several losing battles, Alfred made peace with the invaders. But the Danes renewed their attacks and defeated Alfred at the Battle of Chippenham in 877. Alfred then defeated the Danes at the Battle of Edington in 878. The Danish leader, Guthrum, agreed to be baptized a Christian. He also agreed to stay north and east of the River Thames, in an area called the Danelaw. However, the Danes broke the peace, and Alfred renewed the war. He won London in 886. All the English people not subject to the Danes recognized Alfred as their ruler and paid him homage. The old, independent Anglo-Saxon kingdoms began to merge under the rule of Wessex.

Alfred built forts and *boroughs* (fortified towns) at strategic points. He stationed his fleet along the coast as protection against further invasions. He also issued a code of laws to restore peaceful government.

Before Alfred, education had declined in England because the Danes had looted monasteries and churches, the centers of learning. Alfred revived learning by bringing teachers and writers from Wales and continental Europe. He encouraged the translation of famous Christian books from Latin into Old English. Under his influence, the *Anglo-Saxon Chronicle* began to be compiled. It is now the main source for Anglo-Saxon history up to 1154. Joel T. Rosenthal

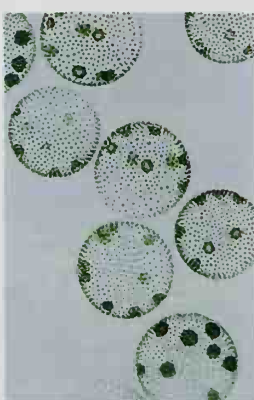
See also Anglo-Saxons; England (The Anglo-Saxon period).

Alfvén, Hannes Olof Gösta (1908-1995), a Swedish physicist, won a share of the Nobel Prize for physics in

1970 for his research in magnetohydrodynamics (MHD) and plasma physics. Magnetohydrodynamics is the study of the ways in which electric and magnetic fields interact with fluids that conduct electricity.

Alfvén developed MHD and applied it to the study of *plasma,* a gas composed chiefly of electrically charged particles. He showed that plasma passing through a magnetic field produces electromagnetic waves. These waves, called *Alfven waves,* help explain the behavior of plasma, which makes up more than 99 percent of all matter in the universe. The results of Alfvén's work have been used in astrophysics and space science and in designing *fusion reactors* (see **Nuclear energy**).

Alfvén was born in Norrköping, Sweden, and earned a Ph.D. degree in physics from the University of Uppsala. He joined the faculty of the Royal Institute of Technology in Stockholm in 1940. In 1967, Alfvén became a professor of applied physics at the University of California at San Diego. Richard L. Hilt



Algae, *AL jee,* are simple organisms that live in oceans, lakes, rivers, ponds, and moist soil. A single organism of this type is called an alga. Some algae are microscopic and consist of just one cell, and others are large and contain many cells. Some species drift or swim, and others are attached to stones or weeds in the water. Large marine algae are called seaweeds. A few algae live on land, growing on trees or other land plants, soil, and rocks. Others live on sloths or turtles. Still others grow within plants or animals.

All algae contain chlorophyll. They help purify the air and water by the process of photosynthesis. Algae also serve as food for fish and other animals that live in the water.

Some algae multiply rapidly in polluted lakes and rivers. Thick layers of algae, called *algal blooms,* may form when waste materials, such as sewage and fertilizers, are dumped in the water. The increased algal population sometimes upsets the natural balance of life in water. The water eventually may become extremely low in oxygen and unfit for use by people.

Most botanists classify the blue-green algae, also called *cyanobacteria,* with bacteria as members of the kingdom Prokaryotae. They classify all other algae in the kingdom Protista.

E. R. Degginger

Many microscopic varieties of algae grow in oceans, lakes, ponds, and streams. The blue-green alga *Anabaena, left,* consists of long strands of single cells. The spherical colonies of the green alga *Volvox, right,* consist of many cells.

Blue-green algae

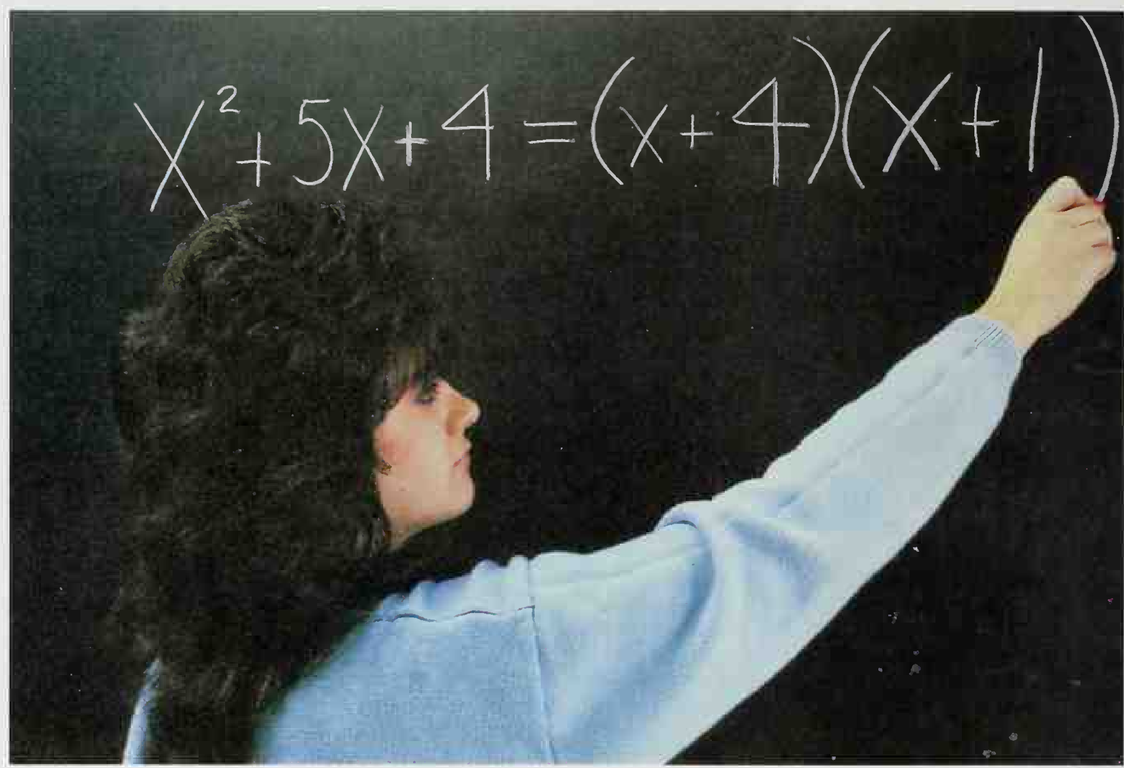
Some kinds of blue-green algae form slippery, dark coatings on rocks along the shores of rivers, lakes, and oceans. Others occur in soil, forming a slimy layer on wet ground. Lakes with large numbers of blue-green algae look greenish or bluish-green. A few species of blue-green algae may poison fish or cattle and other animals that drink water containing these organisms.

Most blue-green algae can be seen only with a microscope. Some species have only one cell. In others, the cells form strands. The cells of blue-green algae lack a distinct nucleus. Besides chlorophyll, they contain blue or red *pigments* (coloring matter). The combination of pigments causes some to appear pinkish, brownish, or black. Many species can take nitrogen from the air, convert it to compounds called *nitrates,* and so help to fertilize soil or water. Most blue-green algae reproduce only by cell division.

Other kinds of algae

All other algae have cells with at least one nucleus. The cells contain chlorophyll and other pigments in specialized cell parts called *chloroplasts.* These algae are generally grouped according to color—brown, green, or red. They grow and reproduce by cell division. Most kinds can also reproduce sexually.

This broad group of algae includes *diatoms* and *dinoflagellates,* most of which have only one cell. Many of these algae occur with marine animals in drifting masses called *plankton.* Dinoflagellate cells swim by means of two hairlike structures called *flagella.* Diatoms have cell walls made up of silica. These "skeletons" resist decay and may accumulate on the ocean floor. In some places, they form a whitish material called *diatomite,* which has many industrial uses. See **Diatom; Plankton.**



Brown algae are plentiful along many seashores of temperate zones. Some kinds, called *kelps,* grow as much as 200 feet (60 meters) long (see **Kelp**). *Algin,* a gummy substance obtained from kelp, is used to thicken cosmetics, ice cream, mayonnaise, and other products. Some brown algae are used as fertilizer.

Green algae occur in both fresh and salt water. Most species are microscopic and live in lakes, ponds, and streams. Large quantities of such algae may color an entire lake. Other species are larger and grow along seashores. Many coral beaches of the tropics consist of pieces of green seaweeds filled with lime. Some scientists are experimenting with growing green algae for food.

Red algae are found mostly in subtropical seas, where they sometimes grow with corals. A few species of red algae live in fresh water. Some red algae have blue as well as green and red pigments. Certain red algae are the source of agar, a gelatinlike substance used in laboratories to grow bacteria. In Japan, people eat a red alga that is called *nori.* It is usually sold dried as papery sheets. Russell G. Rhodes

Scientific classification. Blue-green algae belong to the kingdom Prokaryotae. All other algae belong to the kingdom Protista.

WORLD BOOK photo by Steinkamp/Ballogg

An algebra problem involves letters that stand for unknown numbers.

Algebra is one of the chief branches of mathematics. Mastery of mathematics depends on a sound understanding of algebra. Engineers and scientists use algebra every day. Business and industry rely on algebra to help solve many problems. Because of its importance in modern living, algebra is studied in schools and colleges in all parts of the world.

Unknown numbers in algebra are represented by letters, such as x or y. In some problems, the letter can be replaced by only one number. A simple example would be $x+3=8$. For this statement to be true, x must be 5, because $5+3=8$. In other problems, the letter may be replaced by one of many numbers. For example, for the algebraic statement $x+y=12$ to be true, x would be 6 if y is 6, or x would be 4 if y is 8. In such an algebraic statement, you can find many values for x that make true statements if you give different values to y.

People can use algebra to solve problems in ways that are beyond the range of arithmetic alone. For example:

An airplane travels 1,710 kilometers in 4 hours flying with the wind, but it travels only 1,370 kilometers in 5 hours flying against the wind. The speed of the airplane in relation to the air is the same in both directions, and the wind speed is constant. What is (1) the speed of the airplane in relation to the air and (2) the speed of the wind?

The key to solving this problem is to use letters to represent the two unknown numbers. For example, you might use x to represent the speed of the plane relative to the air, and y to represent wind speed. Using letters in this way is not part of arithmetic, but is an essential part of algebra.

Learning algebra

Sets and variables. Letters in algebra are related to sets of numbers. Everyone is familiar with sets of objects. There are sets of books, sets of stamps, and sets of dishes. Sets of numbers are much the same. In algebra, one way to describe a set of numbers is to use a capital letter, such as N, as a name for the set. Then you list the numbers of the set within braces { }. For example, here is the set of single-digit whole numbers:

$$W=\{0,1,2,3,4,5,6,7,8,9\}$$

Here is the set of odd numbers smaller than 20:

$$Y=\{1,3,5,7,9,11,13,15,17,19\}$$

These are the kinds of sets used in algebra.

Imagine a group of people whose ages are 12 years, 15 years, 20 years, and 24 years. You can write these ages as a set of numbers:

$$A=\{12,15,20,24\}$$

How old will these people be three years from now? One way of answering this question is to write out $12+3$, $15+3$, $20+3$, and $24+3$. However, the number 3 is the same in all four of these expressions. In algebra, you can write all four expressions as one general expression, $m+3$, in which m can be replaced with any number of the set A. For example, you can replace m with 12, 15, 20, or 24.

The letter m is called a *variable,* and the set A is the *domain of the variable.* The number 3 in the expression $m+3$ is called a *constant,* because 3 always has the same value. A variable in algebra is a letter that can be replaced by one or more numbers belonging to a set.

Statements and equations. In mathematics, a *statement* is a sentence that is either true or false. Mathematical statements can be illustrated in everyday language. For example, here is an incomplete statement:

"__________ was the inventor of the telephone."

As it stands, this statement is neither true nor false. Suppose you write a name in the blank:

"__Bell__ was the inventor of the telephone."

Now the statement is true.

You can write a statement with a variable:

"*y* is a state bordered by the Pacific Ocean."

You can replace a variable with the members of its domain. That is, you can replace the variable with names that will produce a true or false statement.

"*Ohio* is a state bordered by the Pacific Ocean."

This statement is false. It is true only when you use Alaska, California, Hawaii, Oregon, or Washington:

"*Oregon* is a state bordered by the Pacific Ocean."

The replacements that make true statements are called *roots.* The set that includes all the roots is called the *solution set.* As with other sets, braces are used to enclose the solution set. The solution set of this example is {Alaska, California, Hawaii, Oregon, Washington}. In algebra, you do not use names to replace a variable. Instead, you use numbers.

Equations are one kind of sentence in algebra. They are mathematical sentences that say two things are equal. Here is a simple equation:

$$7+x=12$$

Terms used in algebra

Binomial is an expression in algebra consisting of two terms connected by + or − symbols.
Coefficient is the multiplier of a variable or number, usually written next to the variable.
Constant is a number or a variable whose domain is a set of one number.
Equation is a mathematical sentence that says two expressions are equal.
Exponent is a number placed at the upper right of a number or variable to show how many times it is to be used as a factor.
Expression, in algebra, is a certain number or variable, or numbers and variables, combined by operations such as addition, subtraction, multiplication, or division.
Factors are two or more expressions that are multiplied.
Monomial is an expression in algebra consisting of a product of numbers and variables.
Polynomial is an expression consisting of two or more terms.
Quadratic refers to a variable that has been *squared* (used as a factor twice).
Roots of an equation are numbers that make a true statement when they are substituted for a variable in the equation.
Term is part of an expression connected to other terms by addition or subtraction symbols.
Variable is a symbol in algebra, usually a letter, that can be replaced by one or more numerical values.

This equation means that "the sum of 7 and a number equals 12." To solve the equation, you can replace x with different numbers until you find one that will make the equation a true statement. If you replace x in this equation with 5, the equation will be a true statement. If you replace x with any other number, the equation will be false. So the solution set to this equation is {5}. The solution set consists of only one root.

Equations can have more than one root:

$$x^2+18=9x$$

The little 2 above the first x means that the number x represents is *squared.* That is, the number is multiplied once by itself (see **Square**). Also, one quantity placed next to another quantity indicates that one quantity is to be multiplied by the other quantity. Therefore, the expression $9x$ means $9\times x$.

In the above equation, you can replace x with 3:

$$3\times3+18=9\times3$$
$$9+18=27$$
$$27=27$$

You can also replace x with 6:

$$6\times6+18=9\times6$$
$$36+18=54$$
$$54=54$$

Any other replacements of x make the equation a false statement. So 3 and 6 are roots of the equation, and its solution set is {3, 6}.

Some equations do not have roots:

$$x=x+3$$

This equation becomes a false statement for any number you use to replace x. Its solution set is called an *empty set.* An empty set is written { }.

Some equations have many roots. Some even have an *infinite* (unlimited) number of roots:

$$(x+1)^2=x^2+2x+1$$

This equation will be a true statement if you replace x with *any* number. Its solution set consists of all numbers.

Mathematicians use a number of terms to describe parts of an equation. They call the expression on each side of the equals sign a *member* of the equation. For example, in the equation $3x+2=11$, $3x+2$ is the left member and 11 is the right member. Each part of a member that is connected by addition or subtraction signs—or stands alone—is called a *term.* Therefore, $3x$ and 2 are the terms in the left member, and 11 is the term in the right member.

Solving equations. The goal in solving an equation with a variable is to isolate the variable on one side of the equation. It does not matter on which side of the equals sign the variable appears because $x=5$ means $5=x$. But most people prefer to have the variable on the left because they read from left to right.

A variable may be isolated by means of subtraction, division, addition, and multiplication. Sometimes, you must perform more than one operation to arrive at the final answer.

Subtraction. If the same number is subtracted from

each side of an equation, the new members remain equal. All roots of the original equation are also roots of the new equation. Thus, for example, you can subtract 2 from each member of the equation $3x+2=11$:

$$3x+2-2=11-2$$

to obtain the new equation

$$3x=9$$

The equation $3x=9$ is equivalent to $3x+2=11$. The roots of either of these equations will solve the other. To isolate the variable of the new equation, you must perform one more operation—the operation of division.

Division. If each side of an equation is divided by the same number, except zero, the new members will be equal. The roots of the original equation are the roots of the new equation. Using this rule you can divide each side of $3x=9$ by 3:

$$\frac{3x}{3}=\frac{9}{3}$$
$$x=3$$

So the solution set of the equation $3x+2=11$ is $\{3\}$. You can prove this by replacing x with 3 in the original equation: $3\times3+2=11$, or $11=11$.

You cannot divide members of an equation by zero. Division by zero is meaningless.

Addition. Another rule for solving algebraic equations is that if the same number is added to each member of an equation, the new members will be equal. The roots of the original equation are roots of the new equation. For example, in the equation $x-6=18$, you can add 6 to each member of the equation to isolate the x on the left side of the equation. That is, $x-6+6=18+6$, and $x=24$. The solution is the set $\{24\}$.

When adding terms with identical variables, the numbers before the variables are added. For example, $5a+2a=7a$. When subtracting terms with identical variables, the numbers are subtracted, so that $8y-3y=5y$.

Multiplication. The last rule for solving simple equations is that if each member of an equation is multiplied by the same number, the new members are equal. It would not be useful to multiply by zero, however, because any number multiplied by zero equals zero.

After multiplying both sides of an equation by the same number, the roots of the original equation equal the roots of the new equation. For example, you can multiply each member of the equation $\frac{1}{4}x = 5$ by 4:

$$4\times\tfrac{1}{4}x=4\times5$$

to obtain

$$x=20$$

Thus, the solution set of $\frac{1}{4}x=5$ is $\{20\}$.

You can use all four rules to find the solution set of the equation

$$\tfrac{2}{3}x-4=\tfrac{1}{4}x+6$$

First, use multiplication to produce an equation that has only whole numbers. Such an equation is easier to solve than one containing fractions. The numbers in the denominators, 3 and 4, have the *common factor* 12 (see Factor). Multiplying both sides of the equation by 12 therefore changes the fractions into whole numbers:

$$12(\tfrac{2}{3}x-4)=12(\tfrac{1}{4}x+6)$$
$$8x-48=3x+72$$

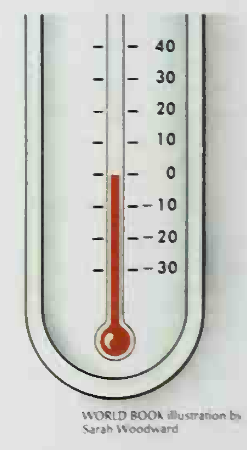
Second, add 48 to each member of the equation to eliminate the 48 from the left side of the equation:

$$8x-48+48=3x+72+48$$
$$8x=3x+120$$

Third, subtract $3x$ from each member to eliminate the $3x$ from the right side of the equation:

$$8x-3x=3x+120-3x$$
$$5x=120$$

Finally, divide each member by 5 to isolate the variable x on the left side of the equation:



$$\frac{5x}{5}=\frac{120}{5}$$
$$x=24$$

The solution set is therefore $\{24\}$. You can verify this by replacing x with 24 in the original equation:

$$\tfrac{2}{3}\times24-4=\tfrac{1}{4}\times24+6$$
$$16-4=6+6$$
$$12=12$$

Since the equation-solving techniques did not produce any other solutions, 24 is the only solution.

Positive and negative numbers. In arithmetic, you can always add, multiply, or divide numbers. But you cannot always subtract. For example, "$3-5$" is meaningless in ordinary arithmetic. Algebra has an extended number system that solves this problem.

WORLD BOOK illustration by Sarah Woodward

In ordinary arithmetic, numbers indicate only size. That is, they show how many or how much. But many everyday measurements indicate both size and direction. The temperature above or below zero is a good example of this. In algebra, we use numbers that show direction.

You can show these new numbers on a scale:

		Below zero				Above zero		
−4	−3	−2	−1	0	+1	+2	+3	+4

The origin or starting point is zero. To the right of zero, the points show positive distance or direction. These numbers are like temperatures above zero. To the left of zero, the points show negative distance or direction. These numbers are like temperatures below zero. Point *A* is not just 1, but +1 or positive one. The + sign shows its direction from zero. Point *B* is not just 1, but

-1 or negative one. The $-$ sign also shows direction. The numbers on this scale are called positive numbers and negative numbers. In everyday life, you can use these numbers to represent temperatures, distances above or below sea level, changes in stock-market prices, business earnings, and many other things. For every positive number, there is a negative number of the same arithmetical size. For example, the number 7 always means seven things, positive or negative. The arithmetical size of a number is called its *absolute value.*

You can add, subtract, multiply, and divide positive and negative numbers, but the rules of these operations are different from those in ordinary arithmetic.

Adding can be illustrated with the problem $(+5)+(-7)$, or the sum of positive five and negative seven. You can work out the solution on the following scale.

If you were adding $(+5)$ and $(+7)$ on a scale, you would count five points to the right from zero, and then count seven more to the right to $(+12)$. To add $(+5)+(-7)$, start at zero on the scale above and count off the first number to be added. This number is $+5$, so you count off 5 to the right. Next, count off in the direction indicated by the second number to be added. This number is -7, so you count off -7 to the left from $+5$. This takes you to the left of 0, to -2. You can read the sum of $(+5)+(-7)$ on the scale: -2. Therefore, $(+5)+(-7)=(-2)$. Numbers with positive or negative signs are often called *signed numbers.* One rule for adding signed numbers has two parts. First, *if the signs are the same, add the absolute values of the numbers and give the sum the common sign.* For example, $(+5)+(+8)=(+13)$ and $(-5)+(-8)=(-13)$. Second, *if the signs are different, subtract the smaller absolute value from the larger absolute value, and give the result the sign of the number with the larger absolute value.* For example, $(+5)+(-8)=(-3)$ and $(-5)+(+8)=(+3)$.

Subtracting. To subtract positive and negative numbers, remember the method of subtraction in arithmetic. The *minuend*$-$the *subtrahend*$=$the *difference:* $9-4=5$. The minuend is the number or quantity from which another is to be subtracted. The subtrahend is the number or quantity to be subtracted. The minuend is also the sum of the subtrahend and the difference: $9=4+5$. In subtracting positive and negative numbers, you must ask what you need to add to the subtrahend to make a sum equal to the minuend. In the problem $(+9)-(-4)$, what can be added to (-4) to make it equal to $(+9)$? One way to solve this subtraction problem is to change it into an addition problem. *Any subtraction problem can be changed into an addition problem by (1) changing the sign of the subtrahend, and (2) adding the minuend and the changed subtrahend.* Using this rule, $(+9)-(-4)$ becomes $(+9)+(+4)$, and $(+9)+(+4)=(+13)$. So $(+9)-(-4)=(+13)$. Using this example, you can see that the sum of the subtrahend and the difference is the minuend: $(-4)+(+13)=(+9)$. Here is another example of the use of this rule: $(-6)-(+8)$. First, change the sign of the $(+8)$. Then add the minuend and changed subtrahend: $(-6)+(-8)=(-14)$.

Multiplying. The rule for multiplying signed numbers is to *multiply the absolute values. If the signs are alike, the product is positive.*

$$(+3)\times(+8)=(+24) \qquad (-3)\times(-8)=(+24)$$

If the signs are not alike, the product is negative.

$$(+3)\times(-8)=(-24) \qquad (-3)\times(+8)=(-24)$$

Dividing. The rule for dividing signed numbers is similar. *Dividing numbers with the same sign gives a positive quotient.*

$$(+24)\div(+3)=(+8) \qquad (-24)\div(-8)=(+3)$$

Dividing numbers with signs that are not alike gives a negative quotient.

$$(+24)\div(-3)=(-8) \qquad (-24)\div(+8)=(-3)$$

When you use negative numbers in algebra, they can extend the domain of the variable. For example, the equation $x+4=1$ has no root with ordinary numbers. With the extended number system, its root is -3. Operations with negative numbers can be applied to variables that represent numbers. That is, you can deal with quantities such as $-x$ or $-y$.

Writing formulas. Algebra uses general formulas to help solve many practical problems in science, engineering, and everyday life. A wide variety of arithmetic situations can be expressed in general formulas.

One example of the use of general formulas involves room dimensions. Consider a room that is 5 meters long and 4 meters wide. Its *perimeter,* or outside measurement, is $5+4+5+4$ meters, or $2\times(5+4)$ meters. If the room is 5 meters long and the width is unknown, you can use w, a variable, to represent the width. The perimeter is then $5+w+5+w$, or $2\times(5+w)$. Going one step further, you can write a formula for the perimeter of *any* rectangular room by using l for the length and w for the width. The formula is $2\times(l+w)$. You can solve many problems with this kind of formula.

Some situations call for an equation. For example, a man collected a sum of money on August 1, and $\frac{1}{3}$ as much on August 2. He collected a total of $6,500. How much was each amount? If n is the amount collected on August 1, then $\frac{1}{3}n$ is the amount collected on August 2. The equation is $n+\frac{1}{3}n=6{,}500$. You can solve this equation to find n. First, multiply both members of the equation by 3 to change the fraction $\frac{1}{3}$ to a whole number:

$$3 \times (n + \tfrac{1}{3}n) = 3 \times 6{,}500$$
$$3n+n=19{,}500$$

Add the terms on the left side of the equation:

$$4n=19{,}500$$

Divide both members of the equation by 4 to find n:

$$n=4{,}875$$

And $\frac{1}{3}n=4{,}875\div3$, or 1,625. Therefore, the man collected $4,875 on August 1 and $1,625 on August 2. To

check this result, add the two amounts collected: \$4,875 + \$1,625 = \$6,500.

Basic algebra

After you learn to work with variables, equations, and signed numbers, you will find that the fundamental principles of algebra are not hard to understand.

Symbols in algebra. The symbol + indicates addition. But in algebra, it also signifies a positive number. The symbol − indicates subtraction and a negative number. You usually do not use × to indicate multiplication in algebra, because it might be confused with the letter *x*. Instead, you use a dot · or no symbol at all. You write *a* multiplied by *b* as $a \cdot b$, $(a)(b)$, or ab. (Note that $3 \cdot 6$ and (3)(6) both mean six multiplied by three, but that 36 still means 36, as in arithmetic.) The symbol ÷ for division is the same as it is in arithmetic.

Parentheses ( ), brackets [ ], and braces { } often enclose quantities or numbers. They are called *signs of aggregation* because everything within them must be treated as a single expression. You must often simplify the enclosed expression before it can be used in other parts of a problem. Here is an example using numbers:

$$\{12+[4+5-(5-3)+4]-4\}$$

First, simplify the group (5−3):

$$\{12+[4+5-2+4]-4\}$$

Second, simplify the group [4+5−2+4]:

$$\{12+11-4\}=19$$

You use the same method to simplify expressions with variables. Here is an example of simplifying groups of variables:

$$\{5a+6a+[5a-a+(3a+4a)]-a\}$$

First, simplify the group $(3a+4a)$:

$$\{5a+6a+[5a-a+7a]-a\}$$

Second, simplify the group $[5a-a+7a]$:

$$\{5a+6a+11a-a\}=21a$$

Sometimes it is useful to remove the parentheses from an expression without simplifying it. You can do this by using the rules for addition and subtraction of signed numbers. For example, the expression $a+(b+c)$ can be rewritten $a+b+c$. To illustrate this, the expression 40+(8−2) means that 8−2, or 6, must be added to 40, or 40+6. Removing the parentheses, 40+8−2, or 48−2, is the same as the simplified expression, 40+6. *If an expression within parentheses has an addition or positive sign before it, you can remove the parentheses without changing the signs of the quantities within the parentheses.* Thus, $a+(-b-c)$ becomes $a-b-c$.

But, *if an expression within parentheses has a subtraction or negative sign before it, you must change the subtraction or negative sign, and you must change the sign of the quantities within the parentheses. That is, you make an addition problem out of a subtraction problem.* Thus, 6−(−8) becomes 6+(+8). Here is another example: 6−(+8) becomes 6+(−8). If there is more than one quantity within the parentheses, you must change the sign of each quantity. For example, 6−(−3+2) becomes 6+3−2, or 7. For this general situation, you can rewrite $a-(b+c)$ as the formula $a-b-c$.

If you want to change the signs of expressions or numbers, you can reverse the process and put them within parentheses. For example, you can rewrite the expression 8+7 as −(−8−7). Or, you can rewrite 8+4−6 as 8−(−4+6).

Fundamental laws. There are five fundamental laws in algebra. These laws govern addition, subtraction, multiplication, and division. They are expressed in variables, and the variables can be replaced with any numbers. Here are the laws:

1. *The Commutative Law of Addition* is written $x+y=y+x$. This means that if you want to add two numbers, you can add them in either order, and the sum will be the same. For example, 2+3=3+2=5, and (−8)+(−36) = (−36)+(−8) = −44.

2. *The Associative Law of Addition* is written $x+(y+z)=(x+y)+z$. This means that if you want to add several numbers, you can add any combination first, and the final sum will be the same. For example, 2+(3+4)=(2+3)+4, or 2+7=5+4=9.

3. *The Commutative Law of Multiplication* is written $x \cdot y=y \cdot x$. This means that if you want to multiply two numbers, you can multiply them in either order, and the product will be the same. For example, (2)(3)=(3)(2)=6, and (−8)(−36)=(−36)(−8)=288.

4. *The Associative Law of Multiplication* is written $x \cdot (y \cdot z)=(x \cdot y) \cdot z$. This means that if you want to multiply several numbers, you can multiply any combination first, and the final product will be the same. For example, $2(3 \cdot 4)=(2 \cdot 3)4$, or 2(12)=(6)4=24.

5. *The Distributive Law of Multiplication over Addition* is written $x(y+z)=xy+xz$. This law can be illustrated with an example: $3 \cdot (4+5)=(3 \cdot 4)+(3 \cdot 5)$. If a number multiplies a sum, for example, 3(4+5), or $3 \cdot 9$, the result is the same as the sum of the separate products of the multiplier and each addend, $(3 \cdot 4)+(3 \cdot 5)$, or 12+15. In this example, you can see that $3 \cdot 9=12+15=27$.

Other definitions. It is important to define some other words used in algebra. An expression consisting of a product of numbers and variables is a *monomial.* For example, $5xy$ is a monomial. This particular monomial contains three elements (5, *x*, and *y*), called *factors,* that multiply each other. An expression with two or more terms connected by addition or subtraction symbols is called a *polynomial.* For example, $x-y+z$ is a polynomial. One kind of polynomial is a *binomial,* an expression with two terms connected by an addition or subtraction symbol. For example, $x+y$ and $3a^2-4b$ are binomials.

A number, variable, or expression that acts as a multiplier is called a *coefficient.* For example, in the expression $5a$, 5 is the coefficient of *a* and *a* is the coefficient of 5. In $a(x+y)$, *a* is the coefficient of $(x+y)$ and $(x+y)$ is the coefficient of *a*.

Addition in algebra is much like that in arithmetic. In algebra, *a* added to *a* is $2a$. The expressions *a* and $2a$ are said to be *like* or *similar* because they contain exactly the same variables. To add two or more like quantities in algebra, you use the Distributive Law. In this way, $2x+3x+4x$ is $(2+3+4)x$, or $9x$. But there is no single term for the sum of *unlike* quantities, such as *a* and *b*. This sum must be written $a+b$. To add $3a$, $4b$, $6a$, and *b*, you can use the Commutative and Associative laws of addition.

These laws permit you to add a series of numbers in any order. First, add the similar terms: $3a+6a=9a$ and $4b+b=5b$. Then, combine the sums. Thus, $3a+4b+6a+b=9a+5b$.

You can use the following form to work out the problem:

$$\begin{array}{r} 3a+4b \\ \underline{6a+\ \ b} \\ 9a+5b \end{array}$$

To add unlike quantities that are both positive and negative, you can use the Distributive Law of Multiplication over Addition. The use of this law can be shown by adding $(2a^3-b^2c+6bd^2+2d^3)$, $(4a^3+3b^2c-4bd^2-3d^3)$, $(3a^3+2b^2c+2bd^2-4d^3)$, and $(-2a^3-8b^2c+6bd^2+6d^3)$. The little 3 above such terms as $2a^3$ means that the number represented by the variable is *cubed.* That is, the number is used as a factor three times (see Cube). To add these terms, you should first arrange like terms in columns:

$$\begin{array}{r} 2a^3-\ \ b^2c+\ \ 6bd^2+2d^3 \\ 4a^3+3b^2c-\ \ 4bd^2-3d^3 \\ 3a^3+2b^2c+\ \ 2bd^2-4d^3 \\ \underline{-2a^3-8b^2c+\ \ 6bd^2+6d^3} \\ 7a^3-4b^2c+10bd^2+\ \ d^3 \end{array}$$

An explanation of the second column illustrates the method of addition. This column is $-b^2c+3b^2c+2b^2c-8b^2c$. Using the Distributive Law, you can see that these terms are the separate products of a multiplier, b^2c. The coefficients are the addends that make up a sum. These addends are -1, $+3$, $+2$, and -8. You can add them together to obtain $(-4)b^2c$, or $-4b^2c$. Use the same method to add the other columns.

Subtraction of products of numbers and variables follows the same rule as the subtraction of signed numbers. To subtract one quantity from another, you must change the sign of the subtrahend and add the two quantities together. In the example $8a-3a$, the sign of both the minuend and the subtrahend is positive. That is, $(+8)a-(+3)a$. Changing this from a subtraction problem to an addition problem converts it to $(+8)a+(-3)a$. The sum of $8a$ and $-3a$ is $5a$.

The subtraction $(2a^3-b^2c+6bd^2+2d^3)-(4a^3+3b^2c-4bd^2-3d^3)$ is more difficult. First, arrange like terms in columns:

$$\begin{array}{r} 2a^3-\ \ b^2c+\ \ 6bd^2+2d^3 \\ 4a^3+3b^2c-\ \ 4bd^2-3d^3 \end{array}$$

Next, subtract the coefficients of like terms by changing the signs in the subtrahend and adding:

$$\begin{array}{r} 2a^3-\ \ b^2c+\ \ 6bd^2+2d^3 \\ \underline{-4a^3-3b^2c+\ \ 4bd^2+3d^3} \\ -2a^3-4b^2c+10bd^2+5d^3 \end{array}$$

Multiplication in algebra is usually indicated by writing two or more expressions together without an operation symbol. For example, $a \cdot b$ is written ab.

When a variable or number is used as a factor more than one time, the multiplication is abbreviated. For example, abb is written ab^2 and $abbbb$ is written ab^4. The little number is called an *exponent.* It indicates the number of times a quantity is used as a factor. Thus, $a \cdot a$ or aa is written a^2. It is called the *square* of a. Next, $a \cdot a \cdot a$ or aaa is written a^3. It is called the *cube* of a. And $aaaa$ is written as a^4, and $aaaaa$ is written as a^5. A variable that occurs only one time as a factor has an exponent of 1. If you are adding or subtracting exponents, you can write a as a^1.

When you multiply like variables, you add their exponents. You can see that $b^2 \cdot b^3$ is $(b \cdot b)(b \cdot b \cdot b)$, or b^5. It is easier to add the exponents: $b^2 \cdot b^3=b^{2+3}$, and $b^{2+3}=b^5$. You cannot combine the exponents in $a^2 \cdot b^2$ because a and b could possibly represent different numbers.

To multiply $abcd$ by bc^2dy, you combine the factors that are alike. In $(abcd)(bc^2dy)$, there are one a, two b's or $b \cdot b$, three c's or $c \cdot c^2$, two d's or $d \cdot d$, and one y. So the product of $abcd$ and bc^2dy is $ab^2c^3d^2y$. The Commutative Law of Multiplication permits you to multiply variables and numbers in any order.

To multiply an expression consisting of two or more terms by a single term or expression, you can use the Distributive Law of Multiplication over Addition: $x(y+z)=xy+xz$. Multiplying $(3bd)(5b^2c+2d)$ shows the use of this law. You can modify the form used in arithmetic for multiplication:

$$\begin{array}{r} 5b^2c+\ \ 2d \\ \underline{3bd} \\ 15b^3cd+6bd^2 \end{array}$$

To find the product in this example, you multiply the terms of $(5b^2c+2d)$ one at a time. First, multiply $5b^2c$ by $3bd$. This product is $15b^3cd$. Write $15b^3cd$ as the first term in the answer. Next, multiply $2d$ by $3bd$. This product is $6bd^2$. Write $6bd^2$ as the second term in the answer. The total product is $15b^3cd+6bd^2$.

To multiply two expressions each consisting of two or more quantities is more difficult. Here is an example. The problem is $(a-b)(a^2-2ab+b^2)$.

$$\begin{array}{r} a^2-2ab+\ \ b^2 \\ \underline{a\ \ -\ \ b} \\ a^3-2a^2b+\ \ ab^2 \\ \underline{-\ \ a^2b+2ab^2-b^3} \\ a^3-3a^2b+3ab^2-b^3 \end{array}$$

First, multiply each term in the multiplicand by the first term of the multiplier. Write the product of this multiplication as part of the answer. Next, multiply each term in the multiplicand by the second term of the multiplier. You can arrange like terms in columns. Write this second product as part of the answer. Last, add the two products to obtain the total product. Notice that arranging like terms in columns helps you do the addition that gives the total product.

Division in algebra is the opposite of multiplication. Remember that to multiply like terms, you add their exponents. To divide like terms, you subtract the exponent of the divisor from the exponent of the dividend. For example, $b^5 \div b^2=b^{5-2}$ and $b^{5-2}=b^3$.

Here is a more difficult problem: $(3x^4y^2z-9x^3yz^2-6x^2y^3)\div(3x^2y)$. In this case, you must divide each part of the dividend in turn by the divisor $(3x^2y)$. For each part,

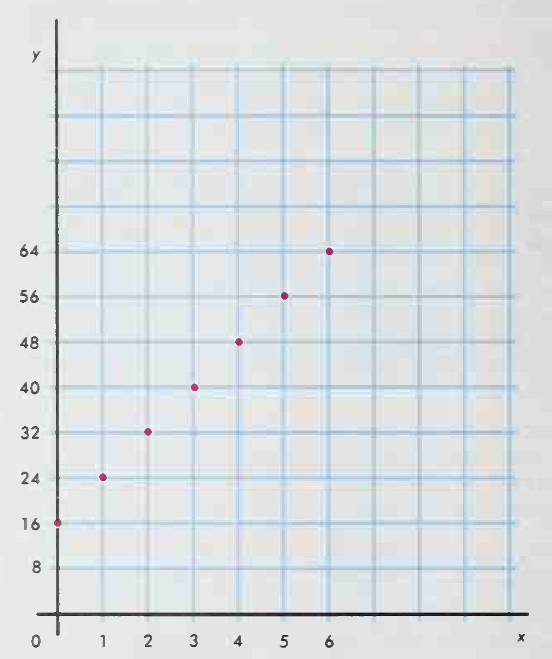
ask what multiplied by $(3x^2y)$ will give that part of the dividend. For example, what multiplied by $(3x^2y)$ will give $(-9x^3yz^2)$? The answer is $(-3xz^2)$. Using this method, $(3x^4y^2z - 9x^3yz^2 - 6x^2y^3) \div (3x^2y) = (x^2yz - 3xz^2 - 2y^2)$.

Here is another problem: $(12a^2 + 18ab + 6b^2) \div (4a + 2b)$. For a problem of this kind, you can use a form somewhat like the form used in arithmetic for long division:

$$\begin{array}{ll} 12a^2 + 18ab + 6b^2 & \\ \underline{12a^2 + \ 6ab\quad} & \\ \qquad 12ab + 6b^2 & \underline{|\,4a + 2b \text{ Divisor}} \\ \qquad 12ab + 6b^2 & \ \ 3a + 3b \text{ Quotient} \end{array}$$

First, divide the first term of the dividend by the first term of the divisor: $12a^2 \div 4a = 3a$. Write the result, $3a$, as the first term in the quotient to the right. Next, multiply both terms of the divisor by $3a$, the first term in the quotient: $(4a + 2b)(3a) = 12a^2 + 6ab$. Write this product below the dividend and subtract it from the dividend. You must account for the result of this subtraction, $12ab + 6b^2$, with a second term in the quotient. To do this, divide 12 ab by the first term of the divisor: $12ab \div 4a = 3b$. And $3b$ proves to be the second term of the quotient. Multiply the divisor by $3b$: $(4a + 2b)(3b) = 12ab + 6b^2$. You can see that there is no remainder.

Factoring means to find expressions that are factors of a given product. For example, $(4a + 2b)$ and $(3a + 3b)$ are factors of $12a^2 + 18ab + 6b^2$. If you multiply $(4a + 2b)(3a + 3b)$, the product is $12a^2 + 18ab + 6b^2$. An expression can have more than one set of factors. For example, 2×12, 3×8, and 4×6 are sets of factors of 24. Factoring is important in algebra because it is used to simplify complicated expressions (see **Factor**).



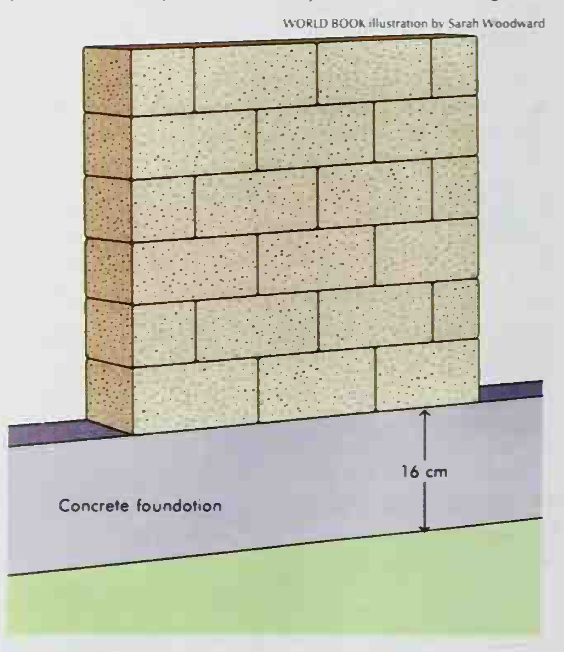
Working with equations

Functions. The amount of gasoline used by an airplane is related to its speed. The amount of postage required for a parcel depends on its weight. The idea of one thing depending on another is important in mathematics. It is called the *relation* of one thing to another. In algebra, a certain relation of two variables is called a *function.*

You can learn the idea of a function from familiar things. For example, imagine a concrete foundation that is 16 centimeters above the level of the ground. On this foundation, you build up 6 layers of stone blocks. Each layer is 8 centimeters thick. As you add each layer of blocks, the height of the pile becomes larger. Use x to represent the number of layers and y to represent the height of the pile. Here is a table showing the relation of the number of layers of stone blocks to the height of the pile.

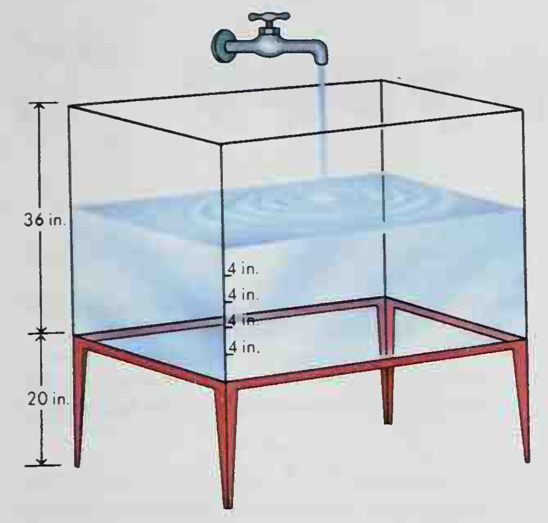
x	0	1	2	3	4	5	6
y	16	24	32	40	48	56	64

You can show the numbers in this table on a graph. Distances along two lines represent the values of x and y. One line is horizontal and shows values of x. The other line is vertical and shows values of y. These two lines



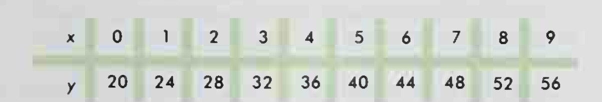
are called *coordinates.* You can plot the number pairs from the table on the graph with 7 dots.

There is an equation that describes this line of dots: $y = 8x + 16$. You can see how the equation fits the table of values. For example, if $x = 2$, then $y = 8(2) + 16$, or 32. If $x = 5$, then $y = 8(5) + 16$, or 56.



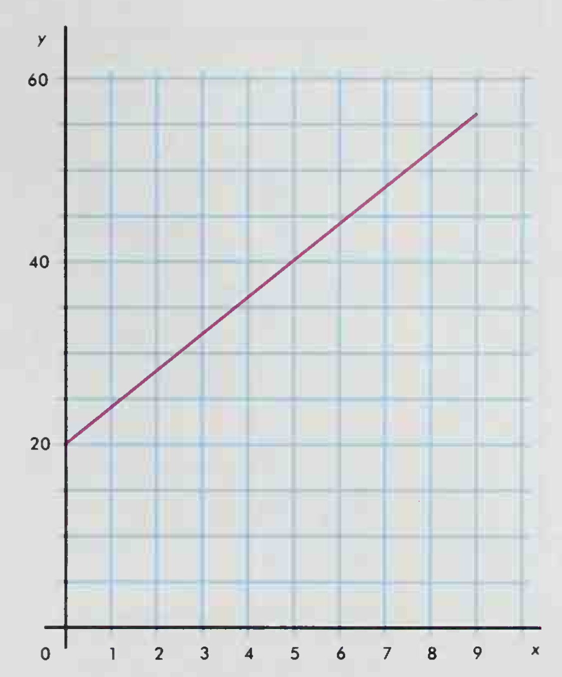
In the equation, the domain of x is the set of numbers $\{0, 1, 2, 3, 4, 5, 6\}$. The values of y are called the *range* of

WORLD BOOK illustration by Sarah Woodward



y. The range of y is the set of numbers {16, 24, 32, 40, 48, 56, 64}. Mathematicians call the relation between the two sets of numbers *a set of ordered pairs*. This set is written $\{(x,y)\} \rightarrow \{(0, 16), (1, 24), (2, 32) \ldots (6, 64)\}$. This set of pairs is a function. It is called a *discrete function* because it cannot be represented by a continuous line. On the graph that appears on page 356, the function is shown by the dots or points.

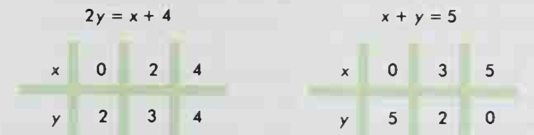
Now, imagine that the bottom of an aquarium is 20 inches above the floor. The aquarium is 36 inches high. Water flowing into the aquarium causes the level of the water in the aquarium to rise 4 inches every minute. This means that the height of the water above the floor is related to the time the water has been flowing. In this example, use x to represent the number of minutes the water has been flowing and y to represent the distance of the surface of the water from the floor. Here are some of the values of x and y:



WORLD BOOK illustration by Sarah Woodward

x	0	1	2	3	4	5	6	7	8	9
y	20	24	28	32	36	40	44	48	52	56

When this relation is shown on a graph, the line is solid because the height of y increases continuously. You can describe this line with an equation: $y=4x+20$. If $x=2$, then $y=4(2)+20$, or 28. You can see how this equation fits the table of values. The domain of x is all numbers between 0 and 9, and the range of y is all numbers between 20 and 56. This function is called a *linear function* because it is continuous and can be represented by a solid line. The equation $y=4x+20$ is called a *linear equation*. The study of linear equations is one of the most important topics in algebra.



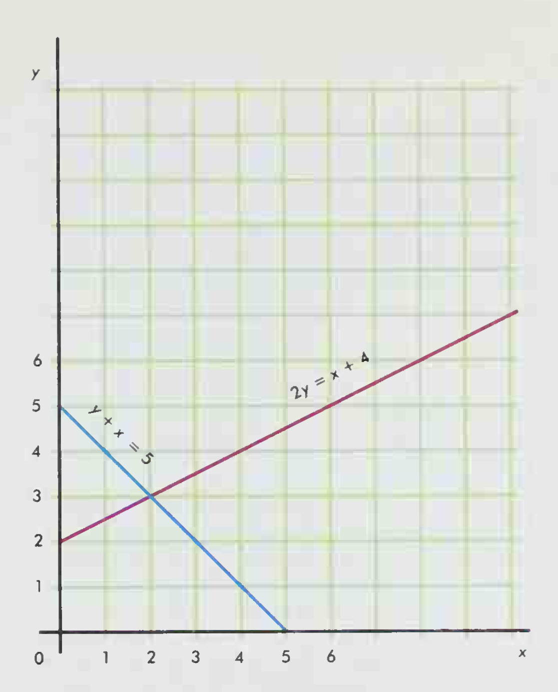
Solving linear equations in two variables. The equation $y=4x+20$ is linear. It has two variables, x and

y. Its continuous line on a graph shows that it has a number of solutions. That is, there are many pairs of numbers that will make $y=4x+20$ a true statement.

Because linear equations have many solutions, it is often useful to find some sort of restriction or limit for them. For example, you might want to use a linear equation to solve a practical problem. To do this, you must find some way to restrict the equation to one set of values. One method is to use a *pair of equations* that are true for only one pair of numbers.

The equations $2y=x+4$ and $y+x=5$ illustrate this method. To solve these equations, you can use a graph. First, make tables of a few of the values that solve each equation.

$2y = x + 4$



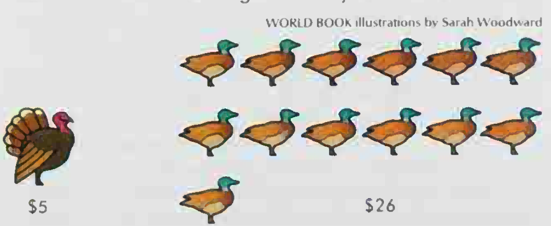
x	0	2	4
y	2	3	4

$x + y = 5$

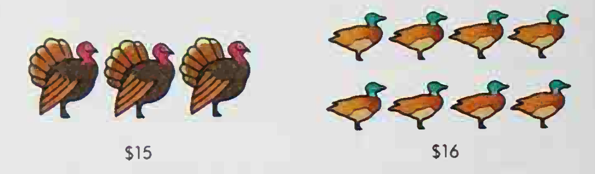
x	0	3	5
y	5	2	0

Plot these points on the graph (as shown on page 358) and draw a line for each equation. The two lines cross. The point where they cross represents the values that will solve both equations. This point is (2, 3). That is, x has the value 2, and y has the value 3. Only these values for x and y will solve the two equations.

You can also solve a pair of linear equations in two variables by eliminating one of the variables. This results in a single equation in one variable. You can use $2y=x+4$ and $y+x=5$ again as examples. There are various ways of eliminating a variable. The method that can be used here is called *substitution*. First, solve one of the equations for y. That is, find what y equals in one of the

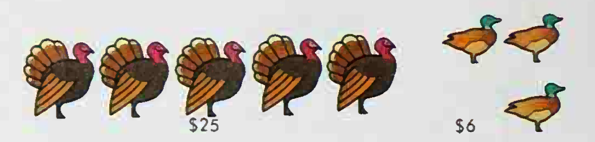


equations. Naturally, you will not know the value of x. Using the equation $y+x=5$, the solution for y is $5-x$. Substitute this for y in the other equation. The other equation is $2y=x+4$. Substituting the new value for y, you obtain $2(5-x)=x+4$. Simplified, this is $10-2x=x+4$. Subtracting 4 from both sides of this equation produces $6-2x=x$. Adding $2x$ to both sides of the new equation produces $6=3x$. Therefore, $x=2$. Now you can replace x with 2 in either of the two equations and find 3 as the value for y. $2y=2+4$ and $y+2=5$. So the solution of the two equations is $\{(2, 3)\}$.



An equation in two variables can also be solved by restricting the solution to positive whole numbers. You can see this in a problem involving a man who bought some prize turkeys and ducks. He spent $31. He paid $5 for each turkey and $2 for each duck. How many of each did he buy? Use x to represent the number of turkeys and $5x$ as their cost. Use y to represent the number of ducks and $2y$ as their cost. You can write this problem as an equation: $5x+2y=31$. You can substitute only whole numbers for x and y because, in this case, you cannot buy part of a bird.

To solve this problem, we use the fact that only an even and an odd number can have the sum 31. Any whole number multiplied by 2 is an even number, so $2y$ is even. This means that $5x$ must be an odd number. Any even number multiplied by 5 is an even number, so x cannot be even. Any odd number multiplied by 5 is an odd number, so x might be any odd number. Replacing x with odd numbers, you will find that the pairs of numbers that solve the equation are (1, 13), (3, 8), and (5, 3). The man could have bought 1 turkey and 13 ducks:



WORLD BOOK illustrations by Sarah Woodward

Or three turkeys and eight ducks:

Or five turkeys and three ducks:

You cannot use 7 for x because the pair would be (7, -2), and -2 ducks is not a solution.

For another method of solving equations in two variables, see Determinant.

Quadratic equations in one unknown. A quadratic equation is one in which the variable is squared. For example, $x^2-8x=-16$ is a quadratic equation in one unknown. By combining terms, you can put any quadratic equation with one unknown variable in the following form:

$$ax^2+bx+c=0$$

In this formula, a, b, and c represent the *known* numbers or coefficients. For example, b is the coefficient of x, and x is the unknown variable. In the simplest example of this kind of equation, the coefficient $a=1$ and the coefficient $b=0$. For instance, if $a=1$, $b=0$, and $c=-36$, then $x^2-36=0$. This means that $x^2=36$ and the solution set is $\{6, -6\}$. If b does *not* equal zero, there are three other methods for solving this type of equation.

The first method is to factor the equation after it has been put in the form $ax^2+bx+c=0$. You can use $x^2+8x+15=0$ as an example. You can factor the left-hand side of this equation: $x^2+8x+15=(x+3)(x+5)$. So $(x+3)(x+5)=0$. If the product of two numbers is zero, one of the numbers must be zero. If $x+5=0$, then $x=-5$. Similarly, if $x+3=0$, then $x=-3$. The solution set of $x^2+8x+15$ is $\{-3, -5\}$.

The second method is called *completing the square*. An expression such as $a^2+2ab+b^2$ is called a *perfect square* because it can be rewritten $(a+b)^2$. You can change an equation such as $x^2+8x+15=0$ so that the left-hand member is a perfect square. To do this, rewrite the equation $x^2+8x+15=0$ as $x^2+8x=-15$. You know that $x^2+8x+16$ is a perfect square because it can be rewritten $(x+4)^2$. You can add 16 to both sides of $x^2+8x=-15$. This gives you $x^2+8x+16=-15+16$. Factoring this, you find that $(x+4)2=1$. One of two equal factors of a number is called its *square root* (see Square root). In the equation $(x+4)2=1$, $x+4$ must equal the square root of 1. The square root of 1 is either 1 or -1. So $x+4=1$ or $x+4=-1$. Then $x=-3$ or $x=-5$. This means that the solution set to $x^2+8x+15=0$ is $\{-3, -5\}$.

The third method for solving a quadratic equation in

one unknown is to use the following formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

You can obtain the coefficients *a*, *b*, and *c* from any quadratic equation put in the form $ax^2 + bx + c = 0$. Substituting these numbers in the formula will give you the value of *x*. In the formula, the symbol ± means positive *or* negative. It also indicates that there will be two roots to the equation.

Here is how to apply the equation to the formula $x^2 + 8x + 15 = 0$:

$$x = \frac{-8 \pm \sqrt{(8)^2 - 4(1)(15)}}{2(1)}$$

$$x = \frac{-8 \pm \sqrt{-4}}{2}$$

$$x = \frac{-8 \pm 2}{2}$$

$$x = \frac{-6}{2}, \frac{-10}{2}$$

Therefore, the solution set to $x^2 + 8x + 15 = 0$ is $\{-3, -5\}$.

History

The ancient Egyptians and Babylonians used algebra. Evidence for its development appears in an Egyptian book that was copied by the scribe Ahmes about 1650 B.C. The Babylonians used more advanced algebra than did the Egyptians. Hundreds of years later, the Greeks, Chinese, and people of India contributed to the development of algebra. Diophantus, a mathematician who lived in the A.D. 200's, used quadratic equations and symbols for unknown quantities. Diophantus, who was probably Greek, has been called "the father of algebra."

The Arabs made many contributions to the study of algebra. They adopted the number system of India, including the zero, and developed fractions much as they are used today. They helped transmit earlier mathematical ideas to the West. Between 813 and 833, al-Khwarizmi, a teacher in the mathematical school in Baghdad, wrote an influential book on algebra that was used as a textbook. The English word *algebra* comes from an Arabic word meaning *restoration* or *completion* in the title of this work. The Persian astronomer and poet Omar Khayyam (c. 1048-1131) wrote a book on algebra.

There was little progress in the development of algebra during the Middle Ages. Europeans began to study the subject in the late 1400's and in the 1500's. Many mathematicians contributed to its later development.

The widespread use of computers has caused major changes in the study and use of algebra. Inexpensive software can perform most problem-solving steps studied in algebra. For example, the programs can quickly solve linear or quadratic equations. The emphasis in algebra classes has therefore begun to shift from learning basic symbol-manipulation skills to understanding algebra's underlying concepts. George W. Bright

Alger, *AL juhr,* **Horatio** (1832-1899), was an American author of novels for boys. He became famous for his stories about boys who rose from poverty to wealth and fame through hard work, virtuous living, and luck. Alger's works reinforced an image of the United States as a land where dreams of material prosperity, high social position, and power could come true. The name Horatio Alger is still used to describe fictional and real-life individuals who achieve "rags to riches" success through their own efforts.

Critics now consider Alger's novels poorly written and dull. But during the latter half of the 1800's, his stories made him one of the most influential writers in the United States. Alger wrote more than 130 books, which sold about 40 million copies. Many of his boy heroes appeared in series, notably *Ragged Dick* (begun in 1867), *Luck and Pluck* (begun in 1869), and *Tattered Tom* (begun in 1871).

Horatio Alger, Jr., was born in Revere, Mass. From 1866 to 1896, he devoted much of his time and money to helping a home for orphans and runaway boys in New York City. Alger used his experiences with the children as material for his novels. Ronald T. Curran

Shostal

Algiers, the capital and largest city of Algeria, is often called *Algiers the White* because of its many white buildings. The city has an excellent harbor on the Mediterranean Sea. Most Algerians live in cities in the country's narrow Mediterranean coastal region.

Algeria

Algeria, *al JEER ee uh,* is a large country in northern Africa. Among African countries, only Sudan is larger.

Northern Algeria stretches along the Mediterranean Sea. The country's narrow Mediterranean region has a warm climate and rich farmland. Almost all Algerians live in this region. Algiers, the country's capital and largest city, lies on the Mediterranean. To the south, the sun-scorched wastes of the Sahara cover more than four-fifths of Algeria. Beneath the surface of this desert area lie huge deposits of natural gas and petroleum.

Most Algerians are of mixed Arab and Berber descent. However, the people form two distinct cultural groups—Arab and Berber. Each group has its own customs and language. But nearly all Algerians are Muslims—that is, followers of Islam.

For about 130 years, Algeria belonged to France. In 1962, it gained independence following a bloody revolution. Algerians then formed a socialist government that began a program of rapid industrial development. The program has been financed chiefly by income from Algeria's government-owned natural gas and petroleum industries. But industry has not grown fast enough to eliminate poverty and widespread unemployment.

Government

National government. A president serves as Algeria's head of state. The president is elected by the people to a five-year term and may serve no more than two consecutive terms. The president appoints a prime minister to head the government. The prime minister in turn chooses a Council of Ministers to help in carrying out the day-to-day operations of the government.

Algeria has two houses in its national legislature, the National People's Assembly and the National Council. The National People's Assembly has 380 members who

Facts in brief

Capital: Algiers.
Official language: Arabic.
Official name: Al-Jumhuriyah al-Jaz'iriyah ad Dimuqratiyah wa ash-Sha'biyah (Democratic and Popular Republic of Algeria).
Area: 919,595 mi² (2,381,741 km²). *Greatest distances*—east-west, 1,500 mi (2,400 km); north-south, 1,300 mi (2,100 km). *Coastline*—750 mi (1,200 km).
Elevation: *Highest elevation*—Mount Tahat, 9,573 ft (2,918 m) above sea level. *Lowest elevation*—Chott Melrhir, 102 ft (31 m) below sea level.
Population: *Estimated 2002 population*—32,813,000; density, 36 per mi² (14 per km²); distribution, 51 percent urban, 49 percent rural. *1987 census*—23,033,942.
Chief products: *Agriculture*—barley, citrus fruits, cork, dates, grapes, meat, milk, olives, potatoes, wheat. *Manufacturing*—machinery, processed foods, textiles, transportation equipment. *Mining*—antimony, copper, iron ore, lead, manganese, mercury, natural gas, petroleum, phosphates, salt, tungsten.
National anthem: "Kassaman" ("We Pledge").
Money: *Basic unit*—dinar. One hundred centimes equal one dinar.

are elected by the people to five-year terms The National Council has 144 members who serve six-year terms. Ninety-six of the members of the council are elected from representatives of local assemblies. The president appoints the other 48.

Until 1989, the Front de Libération Nationale (FLN), or National Liberation Front, was Algeria's only legally permitted party. Today, Algeria is a multiparty state. However, the Constitution bans the formation of political parties based on religion, language, sex, or regional differences. Other important political parties in Algeria today besides the FLN include the Movement of Society for Peace and the National Democratic Rally.

Local government. Algeria has 48 provinces called *wilayas*. Each wilaya has an elected assembly and a *wali* (governor), who is appointed by the president.

Courts. The Supreme Court is Algeria's highest court. It reviews cases from 48 wilaya courts. Wilaya courts hear appeals from lower courts called *tribunals*.

Armed forces. About 120,000 men serve in Algeria's army, air force, and navy. About 85 percent of them serve in the army. Algerian men 19 years or older may be drafted for two years of military duty. Members of the armed forces also work on the construction of highways and other public works projects.

People

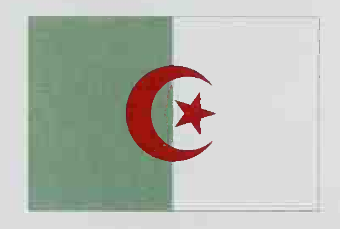
Ancestry. Most of Algeria's people are of mixed Arab and Berber ancestry. Berbers lived in what is now Algeria at least 5,000 years ago. Arabs began to arrive from the Arabian Peninsula during the A.D. 600's. Through the years, so many Arabs and Berbers intermarried that it is now difficult to separate the groups by ancestry. However, many Berbers in the country still maintain their own language and culture. Less than 1 percent of the people are of European descent.

Language. A large majority of Algerians speak Arabic, the country's official language. In addition to Arabic, many Algerians speak French. About a fifth of the people speak dialects of the Berber language.

Way of life. Since Algeria gained its independence from France in 1962, the government has worked to rid the country of French cultural influences. For example, it requires that legal proceedings be in Arabic rather than French. Arabic has also replaced French as the language used to teach the country's elementary and high school students. Many Algerians have called for stricter observance of Islamic teachings, which regulate family and community relationships and many other aspects of daily life.

Rural life. Rural Algerians typically live in large family groups made up of several generations. Most houses are built of stone or concrete or of sun-dried bricks made of mud and straw. Most also have flat tile or tin roofs. The majority of rural Algerians make a living raising livestock or farming small plots.

City life. The architecture of Algeria's larger cities reflects Islamic and European influences. *Mosques* (Islamic houses of worship) and open-air markets are common. Older sections of the cities are called *casbahs*. In these sections, shops and houses are crowded along narrow streets. Newer sections have broad boulevards and tall office and apartment buildings.



In Algeria's cities, many men work in factories or offices. The typical household consists of only a father and mother and their children. City people have much more contact with Western ideas than do rural Algerians. As a result, some city dwellers follow Western customs.

Since Algeria gained independence, many poor rural people have moved to cities to seek factory work. But many of them have not been able to find jobs. The migration and a severe housing shortage have resulted in the growth of large slums in many Algerian cities.

Clothing. Many Algerians, especially in rural areas, wear traditional clothing. A woman may wear a long, white cotton outer garment called a *haik*. It covers the head and the lower part of the face and extends down as far as the feet. Traditional clothing for men includes a long, hooded cloak called a *burnoose*. Many people in urban areas wear Western-style clothing.

Foods made from such grains as wheat and barley form the chief part of the diet of most Algerians. The national dish is *couscous*. It consists of steamed wheat served with meat, vegetables, and a souplike sauce. Many city dwellers eat Western-style dishes.

Recreation. Soccer is the most popular sport in Algeria. Many Algerians enjoy playing the game or watching soccer matches. A favorite pastime in cities is going

Algeria's flag and coat of arms display a star and crescent, symbols of Islam, partly against a background of green, a traditional Islamic color. The flag was officially adopted in 1962, when Algeria gained its independence from France. The Arabic letter *jim*, which appears twice at the top of the coat of arms, is an abbreviation for the Arabic form of *Republic of Algeria*.

WORLD BOOK map

Algeria is a large country in northern Africa. Nearly all its people live in an area that borders the Mediterranean Sea.

to motion pictures. Algerians celebrate several national holidays, including their country's independence day on July 5. They also enjoy a number of religious festivals.

Religion. The Constitution of Algeria declares Islam to be the country's official religion. About 99 percent of the people are Muslims, but they do not all agree about the role that Islam should play in the country's political and social life.

Education. More than half of all Algerians aged 15 or older can read and write. For Algeria's literacy rate, see **Literacy** (table: Literacy rates for selected countries). Algerian law requires all children from 6 to 15 years old to attend school. More than 90 percent of all children attend elementary school. However, only about a third of them go on to high school. The University of Algiers is the country's largest university.

The arts. A large number of Algeria's finest works of art reflect the influence of Islam. Outstanding examples include the beautiful domed mosques found throughout the country. Algerians are also known for their superb jewelry, pottery, rugs, and other handicrafts in which they use distinct Islamic designs and traditional techniques.

Algerian painters and writers were strongly influenced by French culture during the period when Algeria belonged to France. Since then, they have increasingly drawn upon their Arabic, Berber, and Islamic cultural roots. Today, many Algerian painters use traditional

WORLD BOOK map

Sarah Emington, Camerapix Hutchison Library

Algerian townspeople in Timimoun, in the country's Sahara region, wear either traditional or Western-style clothing. The group at the right includes schoolchildren.

Arabic or Berber designs. Numerous Algerian authors now write novels and plays in Arabic instead of in French.

The land and climate

Algeria has three major land regions. They are, from north to south: (1) the Tell, (2) the High Plateaus, and (3) the Sahara.

The Tell stretches about 750 miles (1,200 kilometers) along the Mediterranean coast. The region is from about 80 to 200 miles (130 to 320 kilometers) wide. It consists chiefly of coastal plains and gently rolling hills. The word *Tell* is an Arabic term meaning *hill.* Much of Algeria's best farmland lies in the western and central parts of the region. Rugged mountains cover most of the eastern Tell. Many Aleppo pine, juniper, and cork oak trees grow on the mountain slopes. The Tell Atlas Mountains rise along the region's southern edge. Over 90 percent of Algeria's people live in the Tell.

Near the sea, temperatures in the Tell average 77 °F (25 °C) in summer and 52 °F (11 °C) in winter. Annual rainfall averages 16 inches (41 centimeters) in the west and 27 inches (69 centimeters) in the east.

The High Plateaus lie south of the Tell Atlas Mountains and range from about 1,300 to 4,300 feet (400 to 1,300 meters) above sea level. Herders graze cattle, sheep, and goats on the grasses and shrubs that cover much of the region. During rainy periods, shallow salt lakes called *chotts* form on the plateaus. About 7 percent of the Algerian people live in the region.

Average temperatures on the High Plateaus range from 81 °F (27 °C) in summer to 41 °F (5 °C) in winter. The region receives less than 16 inches (41 centimeters) of rain a year.

The Sahara. The Saharan Atlas Mountains form the northern border of the Algerian Sahara. This vast desert region occupies more than 80 percent of the country. Sand dunes cover much of the northern Sahara. Other parts of the region consist of bare rock, boulders, and stones. A wealth of natural gas and oil lies under the eastern part of the wasteland. In the southeast, the Ahaggar Mountains tower above the desert floor. The range includes Algeria's highest peak, Mount Tahat, which rises 9,573 feet (2,918 meters) above sea level.

Daytime temperatures in the Algerian Sahara sometimes soar above 120 °F (49 °C). During the summer, a very hot, dusty wind called the *sirocco* blows northward across the region. The sirocco parches the High Plateaus about 40 days each summer and the Tell about 20 days.

Less than 3 percent of all Algerians live in the Sahara. Many of the region's people live in oases and rely on underground springs to water such crops as dates and grains. Nomads travel between grazing areas with their camels, sheep, and other livestock.

Economy

Algeria has a developing economy based largely on income from natural gas and petroleum production. The government controls the nation's key industries, including the production of natural gas and petroleum and the manufacture of construction materials, textiles, and iron and steel. However, most farms and small factories and service industries are privately owned.

Service industries account for about 44 percent of the total value of Algeria's economic production and employ about 45 percent of the nation's workers. These industries—which include banks, government agencies, hospitals, insurance companies, and schools—provide business, community, or personal services.

Mining accounts for about 18 percent of the value of Algeria's economic production and employs about 2 percent of the nation's workers. Algeria produces large quantities of natural gas and petroleum, chiefly from fields in the northeastern part of the Sahara region.

Shostal

The High Plateaus region stretches across northern Algeria. The region's grasses and shrubs provide feed for herds of livestock. This shepherd is grazing a flock of sheep near Tiaret.

H. Kanus, Shostal

The Sahara, a hot desert region, covers over four-fifths of Algeria. Date palm trees, such as the ones shown here, grow in oases, where they are watered by underground springs.

Other important minerals produced in Algeria include iron ore, lead, mercury, phosphate rock, and zinc.

Manufacturing and construction account for about 26 percent of the value of Algeria's economic production and employ about 30 percent of all workers. The nation's chief manufactured products include construction materials, iron and steel, refined petroleum products, liquid natural gas, and textiles. Almost all Algerian factories are on or near the coast in such cities as Algiers, Annaba, Arzew, Constantine, and Skikda.

The government has poured much money into the construction of factories. But the industries have not grown fast enough to provide jobs for all workers. Thus, hundreds of thousands of Algerians work in foreign countries, especially France.

Agriculture provides a living for about 22 percent of Algeria's workers and generates about 11 percent of the value of the country's economic production. Most farmers own small plots on which they produce enough to feed their families. Other farmers work on large government farms. Grains, especially wheat and barley, are the chief crops. Other crops include dates, grapes, olives, potatoes, and citrus fruits. Dairy products and meat come from cattle, goats, and sheep.

Trade. Natural gas, petroleum, and refined petroleum products account for about 90 percent of the total value of Algeria's exports. Algeria belongs to the Organization of Petroleum Exporting Countries (OPEC), an association of countries whose economies depend heavily on oil exports. Other Algerian exports include citrus fruits, dates, iron ore, mercury and phosphate rock. Algeria imports large amounts of machinery, raw materials, and food. Its main trading partners include France, Germany, Italy, and the United States.

Transportation and communication. Algeria has about 50,000 miles (80,000 kilometers) of roads and about 2,500 miles (4,000 kilometers) of railroad track.

© Daniel Simon, Gamma/Liaison

A gas-processing plant in Arzew changes natural gas into a liquid so that it can be shipped overseas. Natural gas is one of Algeria's most valuable exports.

Nearly all the roads and railroad track lie north of the Sahara. Camel caravans still cross the Algerian Sahara, as they have for hundreds of years. However, aircraft, jeeps, and trucks are also used to move goods and people across the desert. Algeria's chief international airports are in Algiers, Constantine, and Oran. Algiers and Oran are the main seaports. The government controls the country's four daily newspapers. It also operates all radio and television stations.

History

People have lived in what is now Algeria for at least 40,000 years. By about 3000 B.C., nomadic Berbers had begun migrating to the region. They probably came from Europe or Asia. In the 1100's B.C., the Phoenicians, who lived on the eastern shore of the Mediterranean Sea, established trading posts on the Algerian coast.

About 200 B.C., the Romans helped a Berber chieftain named Massinissa form and become ruler of the Kingdom of Numidia in northern Algeria. From 46 B.C. to the A.D. 600's, the area was controlled, in turn, by the Romans, the Vandals, and the Byzantines.

Arab conquest. In the A.D. 600's, Arabs from the Arabian Peninsula began to invade much of northern Africa, including Algeria. This invasion resulted in the spread of Arabic culture throughout northern Africa and into what is now Spain. In Algeria, most of the Berbers adopted Islam—the religion of the Arabs—and, in time, the Arabic language. Many Arabs and Berbers also intermarried.

Ottoman rule. During the early 1500's, Spanish Christians captured Algiers and other Algerian coastal cities. But in 1518, Barbarossa, a Turkish sea captain, gained control of Algiers. He later helped drive the Spanish from most other Algerian coastal areas. Barbarossa joined the areas under his control to the Ottoman Empire, an Islamic empire based in what is now Turkey. Algeria remained a part of the empire until the early 1800's. During that time, ships in the Mediterranean Sea were attacked by private warships under the command of *corsairs* from Algeria and other countries. Raids by Algerian corsairs on the ships of other nations became Algeria's chief source of income.

French rule. In 1830, France invaded and gained control of northern Algeria. The French king, Charles X, hoped an overseas military victory would strengthen his rule in France. The French governed Algeria as part of France. Many French and other Europeans settled in Algeria. These settlers became known as *colons*. Non-French colons were given French citizenship. However, France made it very difficult for Muslims to become French citizens, even though Muslims made up the great majority of the Algerian population. France gave the colons large amounts of Algerian tribal land, and the colons soon controlled Algeria's economy and government. Many native Algerians fought against French rule. In 1847, the French defeated powerful rebel forces led by Abd al-Qadir, a Muslim religious leader. By 1914, France controlled all of what is now Algeria.

As subjects of France, many Algerians fought on the Allied side in World War I (1914-1918). During World War II (1939-1945), Algeria became a battleground. In 1940, France surrendered to Germany. France, cooperating with Germany, formed a government at Vichy in central France. The Vichy government ruled Algeria un-

til 1942, when the United Kingdom, the United States, and other Allied countries invaded and occupied Algeria (see **World War II** [In northern Africa]). After the war, the Allies returned control of Algeria to France.

The Algerian Revolution. After both world wars, native Algerians demanded greater political power. But each time, the colons blocked all reforms that would have given native Algerians a voice in the government in proportion to their population. In 1954, native Algerians formed an organization to fight for independence—the Front de Libération Nationale (FLN), or National Liberation Front. The FLN began a revolution on November 1. It carried out ambushes, assassinations, and bombing raids against the colons and the French forces in Algeria. In response, the French army destroyed orchards and cropland belonging to native Algerians, forced millions of native Algerians into concentration camps, and tortured rebel leaders. By the late 1950's, the army's tactics had aroused strong opposition in France. Peace talks began in 1961. On July 3, 1962, France finally granted Algeria independence. See **France** (History).

Independence. Most colons—about a million of them—fled Algeria during or soon after the revolution. In 1963, one of the rebel leaders, Ahmed Ben Bella, became Algeria's first president. Ben Bella proclaimed Algeria a socialist state and urged workers to take over businesses and farms abandoned by colons.

In 1965, Houari Boumedienne, the army commander, overthrew Ben Bella. Boumedienne began a program of rapid economic development based on government ownership and control of industry. He used income from natural gas and petroleum to build fertilizer plants, steel mills, oil refineries, and other factories.

Recent developments. Boumedienne died in 1978. In 1979, Defense Minister Chadli Bendjedid was elected president. He slowed industrial development to devote more resources to producing agricultural and consumer goods. From independence until 1989, the FLN was the only political party allowed by Algeria's Constitution. But a 1989 revision permitted other parties to operate. The main opposition party, the Front Islamique du Salut (FIS)—or Islamic Salvation Front—claimed that changes in the electoral law favored the FLN.

A first round of multiparty elections for the National People's Assembly was held in December 1991, with a second round scheduled for January 1992. But the government canceled the second round after it seemed that the FIS would win a majority of seats. The government dissolved the Assembly, and President Bendjedid resigned. A military-dominated High State Committee then governed Algeria until 1994, when the committee was replaced by a president, Liamine Zeroual. In 1995, Zeroual was elected president in a multiparty election.

The courts banned the FIS in 1992, and thousands of FIS members were arrested. Violence increased as the FIS and other Muslim extremists continued to protest against the government. In June 1999, the Islamic Salvation Army, the armed branch of the FIS, announced it was ending its fight against the government. However, some Muslim extremists have continued to attack Algerian security forces and civilians. More than 100,000 people have died in the fighting since 1992.

In 1996, the Algerian people approved a revised constitution that bans parties based on religion, sex, language, or regional differences. Multiparty elections for the National People's Assembly were held in 1997. In 1999, Abdelaziz Bouteflika, an independent candidate supported by the military and Zeroual, was elected president in a contest marred by charges of vote fraud.

In 2001, clashes broke out between security forces and Berber protesters in northern Algeria. The protesters demanded greater political and cultural recognition for Berbers. The government agreed to some Berber demands. In 2002, for example, it made the Berber language, Tamazight, a national language of Algeria. But Berber protests continued. Kenneth J. Perkins

How do Algerians in oases water their crops?
What is the *sirocco?*
How does the Algerian government support Islam?
Why have many rural Algerians moved to urban areas?
Why did France invade Algeria in 1830?
In which land region do most Algerians live?

Algiers, *al JEERZ* (pop. 1,886,000), is the capital and largest city of Algeria. The city is also the nation's commercial and financial center. Algiers lies in northern Algeria, on the Mediterranean Sea (see **Algeria** [map]).

Algiers was built on top of a hill. The oldest section of the city is the Casbah in the north. The Casbah has a large population, and its many old buildings are crowded close together. This section was named for the *casbah* (fortress) that still stands on the hill. The commercial, governmental, and residential areas of Algiers are down the hill and in the suburbs. White buildings, constructed in the late 1800's, line the waterfront. Algiers has a number of museums and *mosques* (Islamic houses of worship) and is the home of the University of Algiers.

Many of the city's people work for the national government. Others are employed in banking and international trade or in industry. The city's industries include food and tobacco processing, metalworking, and the production of cement, chemicals, soap, and shoes.

Algiers was founded in the A.D. 900's by the chief of a Muslim tribe called the Sanhaja. The Ottoman Empire ruled the city from the early 1500's until 1830. The French took control of Algiers that year. They brought to Algiers a European culture, which blended with the city's Muslim culture. Algiers was a colonial capital for many years under Ottoman and then French rule. It became the national capital in 1962, when Algeria gained independence from France. The population of Algiers has increased several times since 1954, causing severe overcrowding in the city. Construction of a subway system to ease the city's transportation problems was begun in the late 1980's. Malcolm C. Peck

Algin. See **Algae; Seaweed.**

Algol, *AL gahl,* also called Beta Persei, is the second brightest star in the constellation Perseus. It is about 100 light-years from the earth (see **Light-year**). Algol appears to be a single star, but it is actually a type of double star called an *eclipsing binary.* In such a binary, a pair of stars revolve around each other so that one periodically blocks the light of the other. This action reduces the brightness of the double star as viewed from the earth.

Algol's variations in brightness can be seen with the unaided eye. About every three days, Algol loses two-thirds of its brightness in a period of five hours. In another five hours, it returns to its normal apparent magnitude of 2.3 (see **Star** [Brightness of stars]). Algol was one of the first eclipsing variables to be discovered.

The distance between the centers of the two stars is about 7 million miles (11 million kilometers). One star has a surface temperature of about 22,000 °F (12,000 °C). The second, fainter star is only one-third as hot. A third, more distant star belongs to the Algol system. It orbits the other two stars, but it does not take part in the eclipses. Sumner Starrfield

See also **Astronomy** (map: The stars and constellations of the Northern Hemisphere); **Binary star.**

Algonquin Indians, *al GAHNG kihn* or *al GAHNG kwihn,* once fished and hunted in the Ottawa River region of Canada, in what is now Ontario and Quebec. They are also called the *Algonkin.* The Algonquin, Cree, and other tribes spoke Algonquian languages, a group of related languages named for the Algonquin. These tribes had strong similarities, and scholars use the term *Algonquian Indians* or *Algonquian family* to refer to all of the Algonquian-speaking tribes.

The Algonquin lived in bands of 100 to 300 members. Each band was divided into hunting groups of up to 25 close relatives. Algonquin families lived in lodges made of bent saplings covered with birchbark. Each lodge housed a husband and wife, their young children and unmarried grown-up daughters, and their married sons with their own wives and children.

In winter, the Algonquin hunted deer, moose, and other animals. During the rest of the year, they fished and also gathered wild fruits, nuts, and roots. The Algonquin were experts in building and handling canoes. They traveled by canoe during spring, summer, and fall. In winter, they used toboggans and snowshoes.

The Algonquin believed in a *great spirit,* an especially powerful god. But they believed their lives were affected mostly by ancestral spirits and the spirits of animals, plants, and other natural surroundings. Certain men and women, called *shamans,* were thought to have spiritual powers and served as advisers.

The Algonquin and their allies the Huron fought a bitter war against the Iroquois during the 1600's. About 1640, the Algonquin were defeated and driven from their territory. This war and epidemics of measles and smallpox reduced the Algonquin population from about 4,000 to 1,000 in a 10-year period. Today, there are about 4,000 Algonquin, most of whom live in eastern Ontario and southwestern Quebec. Conrad E. Heidenreich

Algorithm, *AL guh rihth uhm,* is a step-by-step procedure for solving a mathematical problem in a limited number of steps. The instructions for each step are precise. Many algorithms involve repeating the same steps several times and can be carried out by a computer.

Probably the most famous algorithm is *Euclid's algorithm.* It is used to find the greatest common divisor of any two whole numbers, a and b. To use this algorithm, first divide the smaller number (b) into the larger number (a): $\frac{a}{b}$. If the numbers divide evenly, with a remainder (r) of 0, the algorithm ends and b is the answer. But if the remainder is not 0, divide the remainder into the former divisor: $\frac{b}{r}$. Keep dividing each succeeding remainder into the previous divisor until you reach a remainder of 0. Then stop. The last divisor is the greatest common divisor of the original numbers a and b.

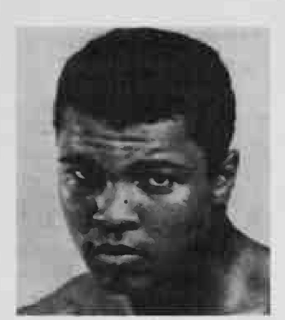
Thomas Butts

Algren, *AWL grihn,* **Nelson** (1909-1981), an American author, is best known for fiction describing the brutal life of the Chicago slums of the 1930's and 1940's. His characters are constantly defeated by their sordid environment, but the reader sympathizes with their yearning for love and dignity.

Algren's most moving and artistic novel is *The Man with the Golden Arm* (1949). It records the unsuccessful struggle of the central character, Frankie Machine, against gambling, drug addiction, and a crippled, neurotic wife. Algren's novel *A Walk on the Wild Side* (1956) has a robust comic quality. Algren also wrote a collection of stories, *The Neon Wilderness* (1947), and a book of stories and nonfiction pieces called *The Last Carousel* (1973). Algren was born in Detroit, but he lived most of his life in Chicago. Victor A. Kramer

Alhambra, *al HAM bruh,* was a famous palace and fortress in Granada, Spain. It was built by the Moors, a

© Adam Woolfitt, Woodfin Camp, Inc.



The Alhambra is a palace and fortress in Granada, Spain. Built by the Moors between 1248 and 1354, the Alhambra is one of the finest examples of Islamic architecture in Europe.

Muslim people from northern Africa, between 1248 and 1354 (see **Moors**). Now a monument, the Alhambra is one of the most elaborate and important examples of Islamic architecture in the Western world.

An outer wall encloses the Alhambra, which occupies 35 acres (14 hectares). Twenty-three towers rise from this wall, which is made of red bricks. *Alhambra* is an Arabic word meaning *the red.* Colorful, delicately ornamented plaster moldings cover many of the walls and ceilings of the palace. The Alhambra is also noted for its two courtyards. The Court of the Lions, in particular, is famous for its carved columns, its delicate screens, and its fountain (see **Spain** [picture: The Alhambra])

The Alhambra was the last stronghold of the Moors in Spain. In 1492, it was captured by forces of the Spanish monarchs Ferdinand and Isabella. J. William Rudd

Ali, *ah LEE,* **Muhammad,** *moo HAM uhd* (1942-), was an American heavyweight boxing champion. Ali first won the championship by knocking out Sonny Liston in 1964. Some boxing groups recognized Ali as champion until 1967. But he was stripped of the World Boxing Association (WBA) title late in 1964 in a dispute over a contract. The WBA again recognized Ali as champion after he defeated Ernie Terrell in 1967. In the same year, the WBA and other boxing groups stripped Ali of his title when he refused induction into the United States Army. He was also convicted on charges of refusing induction.

Chicago Daily Defender

Muhammad Ali

After his conviction, Ali did not box for $3\frac{1}{2}$ years. In 1971, he suffered his first loss in 32 professional fights when he attempted to regain the heavyweight title from Joe Frazier. Later in 1971, the Supreme Court of the United States reversed Ali's conviction.

Ali regained the heavyweight championship by knocking out George Foreman, the defending champion, in 1974. Early in 1978, Ali lost the title to Leon Spinks in one of the greatest upsets in boxing history. Later in 1978, Ali won the title for the fourth time when he defeated Spinks in a 15-round decision. In 1979, Ali gave up his title and announced his retirement. In 1980, however, he came out of retirement and fought Larry Holmes for the World Boxing Council version of the title. Holmes defeated Ali by a technical knockout. In 1984, Ali was diagnosed with a brain illness called Parkinson disease.

Ali was born Cassius Marcellus Clay in Louisville, Kentucky. He became a professional boxer after winning the light heavyweight title at the 1960 Summer Olympic Games. In 1964, he adopted the Black Muslim religion and changed his name to Muhammad Ali. He discussed his boxing career and religious views in his autobiography, *The Greatest: My Own Story* (1975).

Ali became one of the most colorful and controversial boxing champions. He bragged about his ability and made up poems that scorned his opponents. Early in his career, Ali even predicted the round in which he would defeat his opponent. Bert Randolph Sugar

Alibates Flint Quarries National Monument, *al uh BAHT eez,* is in Potter County in northwestern Texas. The monument has quarries where prehistoric Indians dug stone for weapons and tools. Nearby are ruins of a Pueblo Indian settlement built in the 1100's and 1200's. The monument was authorized in 1965. For area, see **National Park System** (table: National monuments).

Critically reviewed by the National Park Service

Alien, *AYL yuhn* or *AY lee uhn,* is a person who is not a citizen or national of the country in which he or she is living. The legal and social rights of aliens differ in various countries.

The United States recognizes two kinds of aliens, *temporary visitors* and *resident aliens.* A person in the United States as a tourist or on business is a temporary visitor. Temporary visitors may not travel or accept employment without permission from the U.S. government. They are protected under the Bill of Rights. Resident aliens live in the United States on a permanent basis. They generally enjoy the same rights as citizens, but cannot vote or hold public office. *Illegal aliens* are noncitizens living in a country without the proper documents. They may be deported if they are discovered.

The Alien Enemies Act of 1798 gives the president the power "to apprehend, restrain, secure and remove" alien enemies in wartime. The U.S. government first registered aliens in 1940. Robert J. Pranger

See also **Citizenship; Naturalization; Immigration; Smith Act; Deportation.**

Alien and Sedition Acts, *AYL yuhn* or *AY lee uhn, sih DIHSH uhn,* were a series of laws passed by Congress in 1798 to silence opposition to an expected war with France. Neither France nor the United States had declared war, but French and American ships had fought many battles.

The Alien and Sedition Acts consisted of three laws dealing with *aliens* (foreigners) and one dealing with *sedition* (inciting rebellion). The Alien Enemies Act authorized the president to imprison or deport citizens of enemy nations. The Alien Friends Act permitted even citizens of friendly nations to be deported if the president considered them dangerous. The Naturalization Act required a foreigner to live in the United States for 14 years before becoming a citizen. The Sedition Act was used to fine or imprison anyone who encouraged resistance to federal laws or who criticized the government.

The chief supporters were members of the Federalist Party, which controlled Congress. The Federalists generally supported Britain in international disputes. Their opponents were members of the Democratic-Republican Party, which usually sided with France. The Democratic-Republican Party gained much support from recent immigrants to the United States, most of whom were from France or Ireland.

By passing the Alien and Sedition Acts, the Federal-

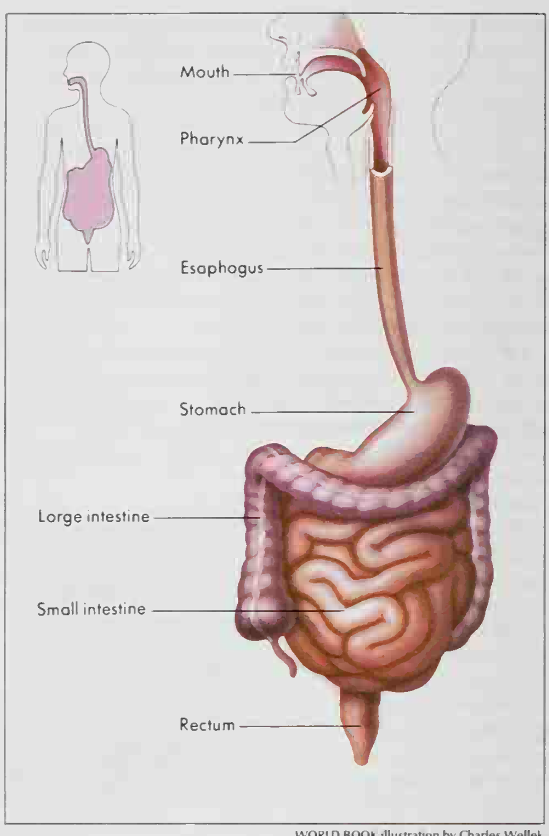
ists hoped to silence their critics. The plan failed, however. Many people objected to the Alien and Sedition Acts as a violation of freedom. Thomas Jefferson and James Madison, two Democratic-Republican leaders, challenged the constitutionality of the acts in the *Kentucky and Virginia Resolutions.* The resolutions became part of the Democratic-Republican platform in the 1800 presidential election. The Democratic-Republicans defeated the Federalists in this election. The Alien Friends Act expired that year, and the Sedition Act expired in 1801. Congress repealed the Naturalization Act, and the Alien Enemies Act was amended. Jerald A. Combs

See also **Kentucky and Virginia Resolutions.**

Alien Registration Act of 1940. See Smith Act.

Alienation is the feeling of being isolated from certain aspects of one's environment. Alienation may occur when a person's emotional ties with another person, group, institution, or belief are disrupted. Sometimes, entire groups become alienated.

There are many causes of alienation. For example, alienation may occur when a group loses a leader who represented its dreams and hopes, or when a child discovers the shortcomings of an adult the child has admired. Or it may result if a person believes that certain political, economic, or social institutions are impersonal and unresponsive to change.



Alienation takes different forms and may have various consequences. Alienated persons may become disoriented or hostile, feel helpless, withdraw within themselves, or reject established values. Many social scientists see a relationship between alienation and such behavior as crime, mental illness, and voter apathy. But alienation sometimes has such positive consequences as artistic creation, invention, and discovery. It is a theme of much contemporary literature. For a discussion of how one writer deals with alienation, see the article **Kafka, Franz.** Wolf Heydebrand

Alienation of affections is the act of a third person who turns the affection of one family member away from another. In the past, only husbands could sue for alienation of affections, and they could do so only if the third person had interfered with the husband's relationship with his wife. Today, wives also can sue. In recent years, a few plaintiffs have successfully sued for the alienation of a parent's affections. A number of states in the United States prohibit alienation of affections suits. Opponents of the suits argue that they promote family conflict and enable dishonest people to obtain money by threatening to sue for alienation of affections. Barring such suits is also part of a trend in family law to avoid placing blame for the failure of a marriage.

Aidan R. Gough

Alimentary canal is a long tube through which food is taken into the body and digested. In human beings, this passage is about 30 feet (9 meters) long. Animals that eat meat usually have shorter alimentary canals than animals that eat grass. The alimentary canal begins at the mouth, and includes the pharynx, esophagus, stomach, small and large intestines, and rectum.

When a person swallows food, muscles of the pharynx push the food into the esophagus. The muscles in the esophagus walls respond with a wavelike contraction called *peristalsis.* At the same time, the *lower esophageal sphincter* relaxes, allowing the food to pass down to the stomach. In the stomach, fluids lubricate and partially digest the food. The partially digested food is called *chyme.* Contractions of the stomach mix and grind the food into a liquidlike mixture that contains small particles. This mixture is emptied into the small intestine. There, juices from the pancreas, liver, and intestine wall continue the process of digestion. The intestine squeezes the chyme back and forth to mix it thoroughly. The frequency and pressure of these contractions varies and keeps the chyme moving through the intestine.

WORLD BOOK illustration by Charles Wellek

The alimentary canal is a tube through which food is taken into the body and digested. It is about 30 feet (9 meters) long in an adult, beginning at the mouth and ending at the rectum.

Most of the food elements in the digested food are absorbed into the bloodstream through the small intestine. The intestine is lined with a mucous membrane made up of tiny fingerlike projections called *villi.* The villi increase the area through which absorption can take place. Soluble parts of the chyme pass through the small intestine into the bloodstream, and are carried to all parts of the body. The water and salts that remain are absorbed in the large intestine. The remaining solid wastes, called *feces,* are mixed with bacteria. The feces pass out of the body through the rectum in a process called *defecation.* Andre Dubois

Alimony, *AL uh MOH nee,* is support money paid by one *spouse* (husband or wife) to the other during a legal separation or after a divorce. A court sets the amount of alimony and orders that it be paid either in a lump sum or in installments. A person may also be ordered to pay alimony while waiting for a separation or divorce to be granted. In some states, the law does not provide for alimony. See **Divorce**.

In many cases in the past, a divorce was granted to one spouse because of misconduct by the other. The marriage partner who was found at fault would not receive alimony. In many states today, courts can grant a divorce without finding either person guilty. These courts base alimony decisions on the spouses' financial condition. A court may order that no alimony be paid, or that it be paid only temporarily. If the wife has a higher income than her husband, she may have to pay alimony.

People who fail to pay alimony may have payments taken out of their wages, or they may be imprisoned. An alimony order may be changed if either spouse's financial or marital condition changes. Carlfred B. Broderick

Alinsky, *uh LIHN skee,* **Saul David** (1909-1972), won fame for his efforts to help poor people help themselves. A professional organizer, he helped the poor in more than 40 U.S. communities to form groups to gain a voice in local affairs and improve their economic and social positions. These groups used various methods of social protest, including boycotts, picketing, rent strikes, and sit-down strikes.

Alinsky was born in Chicago. He graduated from the University of Chicago in 1930. His first community action project was the "Back-of-the-Yards" program in the stockyards area of Chicago in 1939. In 1940, several wealthy Chicagoans gave him money to establish the Industrial Areas Foundation. Alinsky continued his work through this organization. One of his best-known achievements was the creation in 1960 of The Woodlawn Organization (TWO) in a predominantly black neighborhood in Chicago. In 1969, Alinsky founded a school in Chicago to train organizers for work in poor and middle-class neighborhoods.

James W. Vander Zanden

Alkali, *AL kuh ly,* in chemistry, refers to six chemical elements that are known as the alkali metals: lithium, sodium, potassium, rubidium, cesium, and francium. These elements make up group 1 of the periodic table. Compounds of alkali metals rank among the most common and most useful of all chemicals. Millions of tons of alkali metal salts are used by industry each year. The salts come from mines and wells. Sodium and potassium salts are raw materials for sodium hydroxide and potassium hydroxide. These alkali metal compounds and others made from them are used in making glass, paper, soap, and textiles; in refining petroleum; and in preparing leather. The word *alkali* comes from the Arabic word *al-qili,* meaning *plant ashes.* Plant ashes were the first source of alkali metal compounds.

When used alone, the word *alkali* refers to alkali metal hydroxides, and sometimes to alkali metal carbonates. An *alkali metal hydroxide* is a compound that contains an alkali metal positive ion (such as Na^+) and a negative *hydroxide* (OH^-) ion. Sodium hydroxide ($NaOH$) and potassium hydroxide (KOH) are alkalis. When the term *alkali metal* precedes another word, as in *alkali metal halide,* it refers to the presence of a positive ion of an alkali metal. The salt sodium chloride ($NaCl$) is an alkali metal halide. It is made of the positive ion of the alkali metal sodium, and the negative ion of the halogen chlorine.

In nature, alkali metals always occur in compounds. A process called electrolysis can separate the metals from their salts and hydroxides. The average sample of the earth's crust is about 3.13 percent sodium, 2.85 percent potassium, 0.034 percent rubidium, 0.034 percent cesium, and 0.007 percent lithium. Francium, a radioactive alkali metal, occurs only briefly when uranium decays.

With the exception of minerals known as common silicates, most alkali compounds dissolve easily in water. Rain washes these compounds from the soil. The compounds then collect in the ocean and in lakes that have no outlets, such as Great Salt Lake in Utah. The evaporation of ancient seas and lakes left vast deposits of alkali salts throughout the world.

The alkali metals all form singly charged positive ions, and are extremely reactive chemically. They react violently with water, forming hydroxides and releasing hydrogen gas and heat. Duward F. Shriver

Base	Francium	Potassium
Cesium	Lithium	Rubidium
Element, Chemical	Lye	Sodium

Alkaloid, *AL kuh loyd,* is any of a group of organic bases found in plants. Alkaloids contain carbon, hydrogen, nitrogen, and oxygen. Small amounts of many alkaloids can have a powerful effect on people and animals, and are used as medicines or poisons. Some useful alkaloids are *synthesized* (artificially put together) in chemical factories, as well as taken from plants.

Alkaloids with medicinal value include codeine and morphine from the poppy plant, and quinine and quinidine from the cinchona. Others are caffeine from coffee and tea, cocaine from coca, ephedrine from the *Ephedra* genus of plants, reserpine from *Rauwolfia serpentina,* and tubocurarine from curare.

Poisonous alkaloids from such plants as curare are used on arrowheads by peoples who hunt chiefly with bow and arrow. The hemlock plant, which was used to kill the Greek philosopher Socrates, contains lethal amounts of conine and other alkaloids. Aconitine from the aconite plant is also highly poisonous. Nicotine, an alkaloid of the tobacco plant, is toxic to human beings and is also used to kill insects. Patrice C. Bélanger

Aconite	Morphine
Base	Nicotine
Caffeine	Quinine
Cocaine	

Alkalosis, *AL kuh LOH sihs,* is a condition in which a person's body fluids become too alkaline. The body adjusts to mild alkalosis. Severe alkalosis can result in muscular weakness, convulsions, coma, and even death.

Most cases of alkalosis arise from disorders or drugs that cause the body to lose too much acid, thus upsetting the normal balance of acid and alkali. Disorders that can result in alkalosis include prolonged vomiting and *hyperventilation* (abnormally rapid, deep breathing).

Prolonged vomiting causes excessive loss of hydrochloric acid from the stomach. In hyperventilation, a person exhales too much carbon dioxide, lowering the level of carbonic acid in the blood. Alkalosis can arise from prolonged use of such drugs as *diuretics,* which increase the flow—and the acidity—of urine from the kidneys.

Treatment of alkalosis usually consists of correcting the underlying disorder or reducing the drug intake. A solution containing a weak acid may be administered through a vein to help restore the body's normal acid-alkali balance. Edward E. Morse

See also Acidosis.

All Fools' Day. See April Fools' Day.

All Saints' Day is a Christian holy day observed by Western Christians on November 1 and by Eastern Christians on the first Sunday of Pentecost (see **Pentecost**). It honors all Christian saints, especially those who do not have days named for them. Halloween takes its name from All Saints' Day because October 31 was called *All Hallow's Eve,* "eve of all the holy ones' day."

In A.D. 609 or 610, Emperor Phocas gave the Roman temple called the Pantheon to Pope Boniface IV as a church. The pope rededicated it to the Virgin Mary and Christian martyrs. The anniversary of this event may have been the origin of All Saints' Day among Western Christians. In the early 700's, Pope Gregory III dedicated a chapel to all saints on November 1 in St. Peter's church. Some historians think the celebration of that event may have fixed the date of the feast at November 1. The general celebration of the feast day by Christians throughout Western Europe probably began in the 800's.

Richard L. Schebera

Allah, *AL uh* or *AH luh,* is the Arabic name for the Supreme Being of the religion of Islam. The word is a compound of *al* (the) and *ilah* (god). It denotes the Supreme Being in the Quran, which is to Muslims what the Bible is to Christians and Jews. Muslims regularly repeat the creed: "There is no god but Allah; and Muhammad is the Messenger of Allah." Richard C. Martin

Allahabad, *AL uh huh BAD* (pop. 990,298; met. area pop. 1,049,579), is a holy city of India. The name means *City of God.* Allahabad lies in the state of Uttar Pradesh, where the Ganges and Yamuna rivers meet (see **India** [political map]). Hindus consider these rivers sacred.

Allahabad is a trade center for cotton, sugar, and other products of nearby farms. The business and market district lies at the main crossroads of the city.

Allahabad was founded in the 200's B.C. Its old buildings include a famous mosque called the Jama Musjid and an ancient palace and fort built by the Mughal emperor Akbar in 1583. Jawaharlal Nehru, India's first prime minister, was born in Allahabad in 1889. His daughter, Indira Gandhi—who also served as prime minister—was born in the city in 1917. P. P. Karan

Allegheny Mountains, *AL uh GAY nee,* form part of the Appalachian Mountain system of the eastern United States. They extend southwest from central Pennsylvania through western Maryland, eastern West Virginia, and western Virginia.

The Alleghenies vary in height from about 2,000 feet (610 meters) above sea level in the north to more than 4,800 feet (1,460 meters) in the south. Spruce Knob, the tallest peak in the Alleghenies, rises 4,861 feet (1,482 meters) in West Virginia. The mountains form a divide between streams that flow into the Atlantic Ocean and those that empty into the Gulf of Mexico. The Alleghenies are the eastern edge of the Allegheny Plateau. This plateau is the major source of coal used by iron and steel plants in Pittsburgh and nearby industrial areas. Trees from the mountains, including hickories and maples, are shipped to pulp and paper mills and sawmills in the Allegheny region.

Location of the Allegheny Mountains

The Alleghenies are one of the most thinly populated regions in the East. Most of the people live in valleys east of the mountains or on the Allegheny Plateau.

The Alleghenies were created about 230 million years ago by disturbances in the earth's crust. Before that time, the region made up part of a deep ocean trough. About 40,000 feet (12,000 meters) of *sediment* (bits of soil and rock) had piled up in this trough. The upper layers of the sediment once formed the floor of dense, swampy forests. The remains of plants from the forests created the thick coal deposits of the Alleghenies and the Allegheny Plateau.

In pioneer times, the Alleghenies were major barriers to transportation. In 1755, the British general Edward Braddock built a road through a mountain pass called Cumberland Narrows, near Cumberland, Maryland. Part of this road, called Braddock's Road, became part of the National Road, which linked the East Coast and the Ohio River Valley. Today, the pass is the heart of major transportation routes through the Alleghenies.

John Edwin Coffman

Allegheny River, *AL uh GAY nee,* is a major stream of western Pennsylvania and a principal headwater of the Ohio River. It rises in the hilly plateau country of north-central Pennsylvania, curves across the southwest corner of New York, and returns to Pennsylvania. The Allegheny then continues south to Pittsburgh, where it joins the Monongahela River to form the Ohio. The Allegheny is about 325 miles (523 kilometers) long, and drains about 11,400 square miles (29,530 square kilometers).

Its branches include the Kiskiminetas, Clarion, and Conemaugh rivers and Red Bank, Oil, and French creeks. Major deposits of coal, oil, and natural gas lie in the drainage basin. The river is navigable with a channel for 70 miles (110 kilometers), from Pittsburgh to East Brady. William C. Rense

Allegiance, Pledge of. See Pledge of Allegiance.

Allegory, *AL uh GAWR ee,* is a story with more than one meaning. Most allegories have moral or religious meanings. Famous allegories include the *fables* attributed to Aesop, an ancient Greek writer. Aesop's fables seem to describe the adventures of animals and human beings. But the author actually wanted to teach his readers something about human nature.

One of Aesop's best-known fables is "The Fox and the Grapes." On its surface, or its *literal level of meaning,* the story tells of a fox who wants a bunch of grapes hanging above his head. The fox tries desperately to reach the grapes but cannot. He finally gives up, saying that the grapes are probably sour anyway. The *allegorical meaning* of this story is that people may pretend the things they cannot have are not worth having.

Allegories had their greatest popularity during medieval and Renaissance times in Europe. *The Divine Comedy,* written by the Italian author Dante Alighieri in the early 1300's, literally tells of a man's journey to heaven through hell and purgatory. Allegorically, the poem describes a Christian soul rising from a state of sin to a state of blessedness. Other allegories include the *parables* of Jesus, and *The Faerie Queene,* written by the English poet Edmund Spenser in the late 1500's.

Allegories lost popularity in Europe after about 1600, but some, such as *Pilgrim's Progress* (1678, 1684) gained recognition in later times. Allegory also exists in other ways. Many novels include allegorical suggestions of an additional level of meaning. Examples include *Moby-Dick* (1851), a whaling adventure that raises issues of human struggle and fate in a mysterious universe, and *Lord of the Flies* (1954), a story about shipwrecked boys that examines the persistence of evil. Paul Strohm

Allen, Barbara, is the central character in an old British ballad. As with all true ballads, more than one version exists. In most versions, Allen is called to the bedside of a dying man who loves her. She refuses to comfort him, but soon after his death, Allen regrets her lack of pity and dies of remorse. Like all traditional ballads, the focus is on the climax of the action and little is disclosed about the circumstances leading up to it.

A ballad about Allen was first printed in England in 1780, but had existed in oral versions at least 100 years before that date. It was first printed in the United States in 1836 and became very popular. Mark E. Workman

Allen, Ethan (1738-1789), a fiery patriot and soldier, led the Green Mountain Boys in the capture of Fort Ticonderoga from the British in 1775. This was one of the first important American victories of the Revolutionary War. See **Fort Ticonderoga**.

Allen was born on Jan. 21, 1738, in Litchfield, Connecticut. Historians know little of his early life. He served briefly in the French and Indian War in 1757, and then settled in the New Hampshire Grants, now Vermont.

New Hampshire granted land to settlers to the west, but in 1764 the British decreed the land belonged to New York. In 1770, New York courts ruled that land titles in Vermont were not good unless purchased from New York. The settlers resisted this ruling by force. Allen and Seth Warner organized the Green Mountain Boys. They terrorized settlers from New York and fought off officials. New York's governor offered a reward of 20 pounds and later, 100 pounds, for Allen's arrest.

With the outbreak of the Revolutionary War in 1775, Allen and the Green Mountain Boys supported the patriot cause. On May 10, 1775, Allen and Colonel Benedict Arnold led a force of 83 men in the attack on Fort Ticonderoga. They subdued the British garrison and captured cannon and other weapons for the American cause.

In the early fall of 1775, Allen tried to seize Montreal, Canada. Captured by the British and held prisoner until 1778, he wrote *A Narrative of Col. Ethan Allen's Captivity* (1779). After his release, he petitioned the Continental Congress for Vermont's statehood. When Congress refused, he negotiated with the British to make Vermont a British province. Allen was accused of treason, but no one could prove his guilt. He then settled in Burlington, Vermont. A statue of Allen represents Vermont in Statuary Hall in Washington, D.C. James Kirby Martin

Allen, Hervey (1889-1949), was an American author best known for his historical romance *Anthony Adverse* (1933). The story takes place during the era of the French ruler Napoleon I in the late 1700's and early 1800's. It follows the adventures of a young man as he travels through Italy and Africa and finally to New Orleans. Allen's style is rich in historical detail based on his thorough research of the Napoleonic period.

Allen planned a series of novels about colonial America called *The Disinherited.* He completed three works in the series: *The Forest and the Fort* (1943), *Bedford Village* (1944), and *Toward the Morning* (1948). The novels tell the story of Salathiel Albine, a white frontiersman kidnapped as a boy by Shawnee Indians in the 1750's. All three works were collected and published as *The City in the Dawn.* Allen also wrote *Israfel* (1926), a biography of American writer Edgar Allan Poe. William Hervey Allen was born in Pittsburgh. Samuel Chase Coale

Allen, Richard (1760-1831), founded the African Methodist Episcopal Church (A.M.E.), the first African American denomination in the United States.

Allen was born a slave in Philadelphia and grew up on a plantation in Delaware. He later bought his freedom, and moved to Philadelphia in 1786. Allen helped form the Free African Society, a service group for blacks, in 1787. He soon came to believe that blacks should have their own churches, and founded the Bethel African Methodist Episcopal Church in 1794. He was ordained a minister in 1799. In 1816, Bethel ended

its link with the Methodist Church. That year, Allen helped establish the African Methodist Episcopal Church, uniting Bethel with other A.M.E. churches. He became bishop of the new church. Edgar Allan Toppin

Richard Allen

Allen, William (1803-1879), served as an Ohio Democrat in the United States House of Representatives from 1833 to 1835 and in the U.S. Senate from 1837 to 1849. During the Mexican War (1846-1848), he was a Senate spokesman for President James K. Polk. Allen, known as the "Ohio Foghorn" due to his loud voice, supported westward expansion. He threatened war with the United Kingdom to get the Oregon Country, a large area between California and Alaska. He was governor of Ohio from 1874 to 1876.

Allen was born in Edenton, North Carolina. A statue of him represents Ohio in Statuary Hall in the U.S. Capitol at Washington, D.C. Michael F. Holt

Allen, William Cardinal (1532-1594), a prominent English clergyman, defended Roman Catholic beliefs after the Protestant Queen Elizabeth I came to the throne in 1558. He was soon forced into exile. In 1568, Allen founded a seminary in the Spanish Netherlands (now Belgium) to provide priests for England. In 1570, Pope Pius V excommunicated Queen Elizabeth. She, in turn, made it a crime to become a Catholic priest in England. But the college continued to supply priests for England. Many of them were executed. Allen was born in Lancashire. He became a cardinal in 1587. Marvin R. O'Connell

Allen, Woody (1935-), is an American actor, motion-picture director, author, and comedian. Allen won two Academy Awards for directing and co-writing *Annie Hall* (1977). He also won an Academy Award for his screenplay for *Hannah and Her Sisters* (1986), which he directed.

Allen is skilled at depicting the American character in a satirical light. He often satirizes the anxieties and romantic difficulties of intellectual, urban people. In some of his films, Allen portrays a witty but insecure, self-conscious, and rather desperate individual troubled by the lack of values in modern society and by his relationship with women. In addition, this character is often a Jewish outsider yearning for acceptance in the exclusive worlds of Hollywood and the white Protestant community.

Allen was born in New York City. His real name is Allen Stewart Konigsberg. He began his career writing jokes for magazines, newspapers, and television. During the early 1960's, Allen was a popular nightclub comedian. He made his film debut as an actor in *What's New, Pussycat?* (1965), which he wrote. He has turned out a steady stream of highly personal films, which he has written and directed, and which have been shot and edited according to his own creative goals.

Allen wrote, directed, and starred in such comic films as *Take the Money and Run* (1969), *Bananas* (1971), *Sleeper* (1973), *Love and Death* (1975), *Manhattan* (1979), *Zelig* (1983), *Broadway Danny Rose* (1984), *Manhattan Murder Mystery* (1993), *Mighty Aphrodite* (1995), *Everyone Says I Love You* (1996), and *Small Time Crooks* (2000), and in the comedy-dramas *Crimes and Misdemeanors* (1989) and *Husbands and Wives* (1992). He also wrote and directed *The Purple Rose of Cairo* (1985), *Radio Days* (1987), *Alice* (1990), *Bullets over Broadway* (1994), *Celebrity* (1998), and *Sweet and Lowdown* (1999). Allen wrote and directed a few dramatic films, including *Interiors* (1978) and *Shadows and Fog* (1992).

Allen wrote three full-length comic plays, *Don't Drink the Water* (1966), *Play It Again, Sam* (1969), and *The Floating Light Bulb* (1981). He has also written humorous essays and stories. Many of them were published in the collections *Getting Even* (1971), *Without Feathers* (1975), and *Side Effects* (1980). Gene D. Phillips

Allenby, Lord (1861-1936), was a British military leader. During World War I, he led British forces in Egypt and Palestine. By skillfully combining attacks by his own forces with those of Arab guerrillas led by Major T. E. Lawrence (Lawrence of Arabia), he defeated the Turks in 1917 and 1918 (see **Lawrence, T. E.**). His victory at Megiddo in Palestine on Sept. 18, 1918, gave the British control of Syria and Palestine.

Allenby served as British high commissioner for Egypt from 1919 to 1925. Arabs were bitter because the British and French refused to give them independence, and because the Allies had promised the Jews a national home in Palestine. Allenby handled a difficult situation with tact and sympathy.

Edmund Henry Hynman Allenby was born in Suffolk, England. He spent many years with British forces in Africa. When World War I began, he commanded first a cavalry division and then a corps of the British Expeditionary Force in France. He became an army commander in 1915. His full title was Viscount Allenby of Megiddo and Felixstowe. Larry H. Addington

Allende Gossens, *ah YEHN day GOH sehns,* **Salvador** (1908-1973), served as president of Chile from 1970 to 1973, when military leaders overthrew his government. The military leaders reported that Allende committed suicide during the revolt, after refusing to resign from office. Allende had been the first Marxist to be freely elected to lead a nation of the Western Hemisphere. As president, he nationalized Chile's banks and copper mines and many other industries.

Allende was born in Valparaiso. He became involved in politics in 1926 while a medical student at the University of Chile. He earned an M.D. degree at that university in 1932. In 1933, Allende helped organize Chile's Socialist Party. He was elected to the Chamber of Deputies, a house of the Chilean legislature, in 1937. Allende later served as Chile's minister of health. From 1945 to 1970, he served in the Senate. Kalman H. Silvert

See also Chile (Marxism and military rule).

Allentown (pop. 106,632) is a center of manufacturing and high technology in eastern Pennsylvania. The city lies on the Lehigh River, across from Bethlehem. Allentown, Bethlehem, and Easton form a metropolitan area with 637,958 people. For Allentown's location, see **Pennsylvania** (political map).

Factories in Allentown produce clothing, electronic equipment, food products, industrial machinery, metal products, and trucks. The city is also a chief maker of *cryogenic* equipment and gases, used to produce ex-

treme cold for scientific and industrial purposes. Allentown is an important point for pipeline transportation and tank storage of petroleum and natural gas. It is a regional headquarters for several telecommunications companies. Airlines, truck lines, and freight railroads serve the city.

Allentown's downtown business district is laid out around a central square near the Lehigh River. A brick-paved mall forms part of the main shopping street. Brick row houses, many of which were built during the 1800's, are the most common type of housing. Many of the people are descendants of Germans who moved to Pennsylvania during the 1600's and 1700's. They are often called *Pennsylvania Dutch.* Allentown is an important center of Pennsylvania Dutch culture. See **Pennsylvania Dutch.**

Allentown is the home of Cedar Crest College and Muhlenberg College. The city has a symphony orchestra, a professional theater company, and an art museum. The Allentown Band is the oldest municipal band in the United States.

Allentown, originally called Northampton Town, was founded in 1762 by William Allen, chief justice of Pennsylvania. British troops captured Philadelphia in September 1777, during the Revolutionary War. The Liberty Bell was then moved from Philadelphia to Allentown for safety. It remained concealed in Allentown in Zion's Reformed Church until the summer of 1778, when it was returned to Philadelphia. Allentown became an incorporated city in 1867. In the late 1900's, the city carried out a number of development projects to preserve historical districts and rehabilitate housing.

Allentown is the seat of Lehigh County. It has a mayor-council government. William C. Rense

Allergy is a body reaction that occurs in persons who are sensitive to certain substances. A substance that is harmless to a nonallergic person may cause mild to extremely severe symptoms in an allergic person. A person can develop an allergy at any time, but in most cases the first symptoms appear in childhood. About 15 percent of the people in the United States have an allergy requiring repeated medical treatment.

Common forms of allergy include asthma, hay fever, and a year-round nasal allergy called *perennial allergic rhinitis.* Others are *eczema* (itching red swellings on the skin), hives, allergic headaches, and allergic digestive disturbances.

A substance that causes an allergy is called an *allergen.* The allergens that cause most asthma, hay fever, and other respiratory allergies include house dust, mold spores, pollen, and the dandruff or hair of household pets. Many foods may cause allergic reactions. These foods include chocolate, cow's milk, eggs, wheat, and certain seafoods, especially shellfish.

Early human beings probably had allergies, and they still exist in many animals as well as in people. But not until the early 1900's did physicians begin to understand the specific causes and characteristics of allergy. Today, the term *allergy* is often used to refer to a specialized field of medicine. An *allergist* is a doctor who treats allergic diseases.

How an allergy develops. The body of an allergic person reacts to some allergen or allergens to which it previously has been exposed. An allergen is capable of stimulating the body to produce proteins called *antibodies* (see **Protein**). The allergens and the antibodies then act together to release certain substances from the body cells into the blood and other body fluids. These substances, called *H-substances,* bring about reactions in other cells or tissues. Many H-substances can cause allergic reactions in people and animals. The chief H-substance that causes allergy in people is *histamine.*

The H-substances that are released into the body affect *allergic target tissues.* Most of these tissues are *capillaries* (small blood vessels), mucous glands, or *smooth muscles* (muscles of the stomach and of all other internal organs except the heart). The location of these tissues in the body—along with their particular response to H-substances—determines the specific allergic disease. In general, histamine causes capillaries to enlarge, mucous glands to secrete, and smooth muscles to tighten.

After a person's body has produced antibodies in response to a particular allergen, any future exposure to the allergen will stimulate antibody production. But such allergic antibodies do not behave in the same manner as the protective antibodies that a person's body produces to fight infection. The protective antibodies fight disease organisms and destroy them or make them harmless. If the body continues to make such antibodies after the organisms have been destroyed, the person may become immune to the disease.

Emotional factors. The allergen-antibody reaction does not fully explain allergy because the allergic target tissues are under the basic control of the autonomic nervous system (see **Nervous system** [The autonomic nervous system]). The autonomic nervous system tends to keep these tissues in their normal state of balance. But the autonomic nervous system itself is involved in other body responses, such as emotions. As a result, strong emotions may also affect the reaction of an allergic target tissue. Types of emotions that increase the probability of an allergic response include anger, fear, resentment, worry, and lack of self-confidence.

Nerve centers in the brain take part in emotional responses. A part of the brain called the *hypothalamus* constantly checks and controls the autonomic nervous system. The hypothalamus, in turn, is considerably influenced by the *cerebral cortex* of the brain. When certain stimuli come into the brain as a result of seeing or hearing, a message is formulated in the cerebral cortex. If the message is one that could cause any kind of emotional response, it is sent to the hypothalamus. The hypothalamus then sends the message via the autonomic nervous system to the allergic target tissues. If the allergic target tissues receive an emotionally painful message, they become more likely to react to histamine. See **Brain** (In producing emotions).

Hereditary factors. Such allergies as asthma, hay fever, eczema, perennial allergic rhinitis, and certain kinds of allergic headaches tend to run in families. One member of a family may have asthma, another may have hay fever, and still another may have eczema and hay fever. Doctors have observed an inherited tendency to develop allergy. If both parents have an allergy, each of their children has about a 75 percent chance of developing one. If only one parent has an allergy, the probability is 50 percent or less.

An inherited tendency toward allergy apparently does

not follow any strict genetic laws. Therefore, allergy is said to be familial, rather than directly inherited.

The allergic threshold. Many factors besides emotions and heredity can influence a person's reaction to allergens. All patients with an allergy have an *allergic threshold,* the particular level of their body's resistance to allergic disease. The allergic threshold varies, depending on the type and seriousness of various factors at any given time. For example, whether people develop asthma when exposed to pollen or dust may depend on their emotional state or a change in the weather. It also may depend on whether they already have some other disease or are overtired. An increase in one or several of these factors might lower the patient's allergic threshold enough to cause an allergic attack. On the other hand, a decrease in one or more of the factors could raise the allergic threshold and reduce the chances of an attack.

An allergist, when diagnosing and treating any allergy, must consider all the forces acting on a patient that could contribute to that person's condition. This procedure helps explain why the proper treatment of allergy takes so long to establish in many cases.

Diagnosis and treatment. There is no complete cure for allergy. People may be able to avoid the symptoms of a particular allergy by avoiding the allergen that causes it. But they still remain allergic to the substance.

On the other hand, allergy can be controlled. The rate of occurrence and the seriousness of the attacks can be decreased, and complications can be prevented. In most cases, if treatment starts soon after the first symptoms are recognized and continues on a regular basis, it produces good results. An untreated allergy tends to become worse rather than better.

The physician first gives the patient a physical examination and diagnoses the presence of an allergic disease from the person's symptoms. Carefully controlled skin tests are used to identify the allergens causing the trouble. The allergist injects small doses of many of the most common allergens in separate areas just beneath the skin. Substances to which the patient is allergic cause the skin to become red and slightly swollen at the injection site. The procedure generally causes little discomfort and the redness and swelling quickly disappear.

Next, the allergist compares the results of each skin test with the results of the patient's physical exam and medical history. Skin tests do not always provide definite answers, but they serve as guides to identification of allergens. Blood tests and examination of samples of the patient's nasal mucus also help in the diagnosis.

Skin tests cannot identify a food allergy if the food causes an allergic reaction only after it has been changed during the process of digestion. To detect such a food allergy, the physician may put the patient on a controlled diet. The allergist removes from the person's diet all foods that most commonly cause allergic reactions. This step may relieve the symptoms. If so, the physician returns the foods one at a time to the diet. If the allergy flares up again after the person eats one of the foods, he or she probably has an allergy to that food.

After the substance or substances that trigger the allergic reaction have been identified, the patient avoids them as much as possible. This may be fairly easy if the substance is a food, such as chocolate, or the hair of a particular kind of animal. But if the allergen is house dust or ragweed pollen, the person may have an extremely difficult time trying to avoid it.

If the allergen cannot be avoided, the physician may give the patient drugs to relieve the symptoms. Such drugs include the antihistamines and, in more severe cases, steroids.

A treatment called *hyposensitization,* or *desensitization,* is helpful for some types of respiratory allergies, especially asthma, hay fever, and perennial allergic rhinitis. Hyposensitization is aimed specifically at the allergen-antibody reaction. The physician injects an extremely small dose of pollen or other allergen into the body on a regular basis. In most cases, the patient receives injections twice a week for about two months, and then once a week. The doctor gradually increases the amount of allergen up to what is called a *maintenance dose.* The injections cause the body to produce antibodies called *blocking antibodies.* The blocking antibodies combine with the allergens. This combining process results in fewer allergens being left free to react with the regular allergic antibodies.

Alliance. See International relations.

Alliance for Progress, or, in Spanish, *Alianza para el Progreso,* was a cooperative program that promoted economic and social development in Latin America. It involved the United States and more than 20 Latin-American nations. The program began in 1961 and ended during the early 1970's.

In 1961, President John F. Kennedy called for the establishment of the Alliance for Progress. He proposed the cooperative program to replace previous efforts by the United States to help Latin-American countries on an individual basis. The United States and 19 Latin-American countries signed the charter of the Alliance for Progress on Aug. 17, 1961, in Punta del Este, Uruguay. Other Latin-American countries later joined the program.

Under the alliance's charter, the participating Latin-American countries provided 80 percent of the funds for the program. The remainder was furnished by the United States, other wealthy countries, and a variety of public and private groups. During the 1960's, the United States provided nearly $10 billion for projects connected with the Alliance for Progress program. These projects included housing developments, power plants, and roads.

The Organization of American States, an association of Latin-American countries and the United States, coordinated the activities of the Alliance for Progress. United States participation was directed by the Agency for International Development, which was then a part of the United States Department of State. Other United States government agencies involved in the program included the Export-Import Bank and the Peace Corps. International lending agencies, such as the Inter-American Development Bank and the World Bank, also worked with the alliance.

One of the goals of the Alliance for Progress was an

annual economic growth rate of at least 2 $\frac{1}{2}$ percent per nation. Almost all the Latin-American countries exceeded this goal during the 1960's. They also improved their educational systems and programs to benefit the poor. But the alliance was less successful in providing more jobs. Unemployment in much of Latin America remained high, though the alliance had pledged to reduce it. Critics charged that the alliance failed to deal realistically with Latin America's overpopulation problem. Others said the program's goals had been too ambitious. Still others blamed the U.S. Congress, which began to cut funds for the alliance in the late 1960's.

During the early 1970's, the U.S. government began to emphasize increased trade, rather than direct aid, as a means of solving Latin America's economic problems. Also, Latin-American nations were providing more and more of their own development resources. In addition, international lending agencies, especially the World Bank, provided more money for development projects in Latin America. Nathan A. Haverstock

Allies. See **World War I** (introduction); **World War II** (table: The Allies; Strategy).

Alligator is the name of two kinds of reptiles related to crocodiles. The *American alligator* lives in the waters and lowlands of southeastern United States. The *Chinese alligator* lives in the lower Yangtze River Valley, in China. Other related reptiles are the caimans of Central and South America. Caimans are frequently called alligators.

Body. Alligators resemble lizards in their shape, but they have thicker bodies and tails than most lizards. Alligators' jaws are set with many sharp teeth. Their eyes stick up above their skulls so that alligators can see above the water while their bodies are beneath it. They use their short, strong legs for walking. Alligators swim by moving their tails from side to side.

An alligator's skin is tough. The skin on the animal's back is rough and ridged with dozens of small bones called *osteoderms.* The skin on the belly is smooth and was once used to make a handsome, long-lasting leather for handbags, shoes, and other articles. A young American alligator has yellow marks across its body, but these fade after a time. When grown, the American alligator is dull gray and dark olive in color.

Alligators in the past grew to be 18 feet (5.5 meters) long or longer. Today, few can be found that have reached even a length of 12 feet (3.7 meters). Male alligators from 11 to 12 feet (3.4 to 3.7 meters) long weigh from 450 to 550 pounds (204 to 249 kilograms). Females seldom measure more than 9 feet (2.7 meters) long, or weigh over 160 pounds (73 kilograms).

Habits. The female alligator makes her nest of grass and other plants, which she forms into a pile about 3 feet (0.9 meter) high and 7 feet (2.1 meters) across. She lays 20 to 60 eggs in the center of the pile, where the nest is wet. The eggs are white, hard-shelled, and slightly larger than hens' eggs. The young emerge from the eggs after about nine weeks.

Alligators provide more care for their young than do most reptiles. After laying eggs, the female stays near the nest, guarding the eggs against predators. When the young hatch, they give high-pitched yelps, and the mother comes to scratch open the nest and free them. The mother alligator protects her young for a year or more.

When first hatched, the young alligators are about 9 inches (23 centimeters) long. During the first six years of their lives, both males and females grow about 1 foot (30 centimeters) in length each year. After this time, the females grow more slowly. But the males continue to grow at the same rate for several years more. Alligators probably live 50 to 60 years.

In winter, alligators remain resting underwater, bury themselves in mud, or go into deep holes that they have made with their bodies. These holes are called *'gator holes.* During droughts, 'gator holes often provide the only refuge for aquatic animals. When rains return, the fish, frogs, turtles, and other animals that have survived in 'gator holes repopulate the swamps and marshy lakes of the South.

Alligators eat many kinds of small animals that live in or near the water, including fish, snakes, frogs, turtles, small mammals, and birds. Large males sometimes attack dogs, pigs, or even cattle. They drag these animals under water to drown them, and then tear them to pieces. Alligators do this by grabbing hold of a part of their prey with their jaws and twisting until that part comes off. Fortunately, even the largest alligators seldom attack human beings. The muscles that close an alligator's jaws are very strong. But once the jaws are shut, they can easily be held closed by a person's bare hands.

Treat Davidson, NAS

An alligator's body is suited for life on land and in water. The alligator uses its short, stocky legs for walking. In the water, it swims by sweeping its tail from side to side.

Bruce Coleman Inc

The alligator's powerful jaws can crack cattle bones. But if the jaws are shut, they can be held closed by a person's hands.

G. J. Chafaris

A swimming alligator can keep its eyes and nostrils above the water because of the shape of its skull.

People have sometimes captured alligators in this way, without using any weapons.

Alligators and crocodiles. Alligators are often mistaken for crocodiles but are different from them in some ways. The fourth tooth of the alligator's lower jaw fits into a pocket of the upper jaw. The same tooth in the crocodile fits into a groove in the side of the upper jaw, making it visible when the animal's mouth is closed. Another way to tell the American alligator from the American crocodile is that the American alligator has a much broader snout. Alligators are also much less aggressive and active than crocodiles. In the United States, alligators and crocodiles are found together only in the marshes at the southern tip of Florida. Both alligators and crocodiles belong to the great group of crocodilians. This group also includes caimans and gavials. See **Crocodile; Gavial.**

Where alligators live. Alligators were once common in lakes, swamps, and rivers along the Gulf of Mexico and on the Atlantic Coast as far north as North Carolina. They were also found far up the Mississippi River. But so many were killed for their hides or for food and sport that they became scarce. In 1967, the U.S. Fish and Wildlife Service classified the alligator as an endangered species. This designation gave the animal almost complete protection. But by 1977, alligator populations had increased so much in Florida and other southern coastal regions that the animals were reclassified as threatened. This new classification permits tightly regulated hunting of alligators for commercial purposes.

D. Bruce Means

Scientific classification. Alligators are in the crocodile family, Crocodylidae. They make up the genus *Alligator.*

Alliteration, *uh LIHT uh RAY shuhn,* occurs when the same sound starts succeeding accented syllables. In "Peter Piper picked a peck of pickled peppers," for example, alliteration is created by the occurrence of a *p* sound at the beginning of every accented syllable. The first sentence of this paragraph has alliteration of *s* sounds. Old English poetry had no rhyme, but was held together by a pattern of alliteration. Alliteration, like rhyme, assonance, and consonance, is a device of repetition that helps express the feelings and ideas of a poem. Paul B. Diehl

See also **Poetry** (Sounds).

Allopathy, *uh LAHP uh thee,* is a method in medical practice that tries to cure a disease by producing effects on the body that differ from the effects of the disease. The term is sometimes wrongly used to cover all the practices that medicine and surgery use to cure disease and relieve pain. See also **Homeopathy.**

Allosaurus, *AL uh SAWR uhs,* was a large, meat-eating dinosaur that lived about 150 million years ago. *Allosaurus* lived in what is now the western United States, including Colorado, Utah, and Wyoming. It grew about 36 feet (11 meters) long, stood about 7 feet (2 meters) high at the hips, and weighed about 2 tons (1.8 metric tons).

The head of *Allosaurus* was 3 feet (0.9 meter) long. Its jaws had about 70 teeth, each 3 inches (8 centimeters) long with jagged edges for slicing flesh. Holes in the skull lightened the weight of the dinosaur's large head. A pair of distinctive low, bony bumps rose in front of the eyes. The short front legs had three strong, curved claws on each hand. The hind feet were birdlike, with three toes pointing forward and a small inner toe pointing backward. *Allosaurus* walked on two legs with its body parallel to the ground and held its long tail out behind for balance. The animal could rear up to a height of 12 feet (3.7 meters) or more.

Allosaurus preyed on other dinosaurs. Many dinosaurs, including *Apatosaurus* and *Diplodocus,* were much larger, and so *Allosaurus* may have eaten mostly smaller dinosaurs. When *Allosaurus* did eat larger dinosaurs, it may have attacked only the weaker ones, such as the young or the sick. It may also have eaten dinosaurs that had already died. Peter Dodson

See also **Dinosaur** (pictures).

Allotropy, *uh LAHT ruh pee,* in chemistry, is the ability of an element to exist in more than one form. These forms are called *allotropes.* For example, three common allotropes of carbon are: (1) hard, transparent diamond crystals, (2) soft, black graphite crystals, and (3) black, sooty, uncrystallized carbon black (see **Carbon**). The word *allotropy* comes from two Greek words meaning *another* and *way.*

Solid allotropes differ in their crystal structures. But allotropic gases differ in their molecular structures. For example, each molecule of ordinary oxygen is made of two oxygen atoms. Each molecule of the allotrope *ozone* is made of three oxygen atoms. Ordinary oxygen has no odor. But ozone has a peculiar sharp odor (see **Ozone**).

Robert J. Ouellette

Alloy is a material made up of a metal and at least one other element. Most alloys contain a large amount of the main metal, or *base metal,* and smaller amounts of other components. These components can be either metals or nonmetals such as carbon or silicon. Many pure metals are too soft, rust too easily, or have other disadvantages. But often these disadvantages can be overcome if the metals are combined with other elements. Three, four, or more different substances may be present in a single alloy.

People usually make alloys by melting a base metal and adding other components. This liquid alloy then cools and solidifies. Many alloys need to be worked into a final shape after cooling. Other alloys can be made without melting the base metal. For example, manufacturers can blend metal powders together and heat them under pressure. The solid powder particles then bond to form the alloy.

Characteristics of alloys

Alloys consist of tiny crystals called *grains.* In every grain, the atoms are packed together in a particular geometric arrangement. Each grain is tilted differently from those next to it. Manufacturers can control grain size by the way they heat, form, and cool the material. Grain size determines particular characteristics in alloys. For example, smaller grains make stronger alloys. Boundaries between the grains also help determine alloy characteristics. Boundaries can become sources of weakness when an alloy has impurities, or when people use the alloy at high temperatures or with damaging chemicals.

There are two types of alloys: (1) *single phase alloys* and (2) *polyphase alloys.* Single phase alloys consist of grains that all have the same composition. In these alloys, one metal dissolves into another in the same way that salt dissolves into water. A mixture of copper and nickel in any proportion forms a single phase alloy.

Polyphase alloys have different types of grains mixed together. In these alloys, the different atoms bond together in various ways to form strong, stable compounds. The proportion of metals in polyphase alloys is the same in all grains of a particular type. But this proportion can vary significantly from one grain type to another. Steels are polyphase alloys that include some grains of iron containing small amounts of carbon and other grains of a chemical compound called *iron carbide.* Iron carbide has one atom of carbon to every three atoms of iron.

McDonnell Douglas Corporation

Products made from alloys include the steel landing gear and nose on this military airplane, *above.* Steels, like many alloys, are strong materials that resist chemical damage. These properties make them useful in many different industries.

Carpenter Technology Corporation

The structure of an alloy consists of tiny crystals called *grains.* This photograph, taken with a microscope, shows the different grains of a kind of steel. Steels are iron alloys.

Most alloys are stronger and harder than the pure metals from which they are made. Alloys also usually have lower melting temperatures than pure metals. Most alloys are less *ductile* than pure metals—that is, they are more difficult to hammer into shape, roll into sheets, or draw into wires. However, some special *superplastic alloys* are extremely ductile. Few alloys can conduct electricity as well as pure metals. But there are some *superconducting alloys* that are excellent conductors.

Kinds of alloys

The first alloys. People first discovered alloys in nature during prehistoric times. Such alloys included meteorites of iron and nickel and mixtures of gold and silver in river beds. The first alloy made by people was bronze. The oldest bronzes consisted of copper and arsenic. Prehistoric copper smelters first produced them accidentally in about 3500 B.C. Over the next few hundred years, people discovered that mixing tin with copper produced a more useful bronze. They began to make tools, ornaments, and weapons out of this bronze. Bronze is much harder than pure copper, and it is easier to melt and cast into useful shapes.

Alloys of iron. Iron is the most important industrial metal. Manufacturers have almost always used it as an alloy rather than as a pure metal. Iron-based alloys are called *ferrous alloys.*

The most widely used ferrous alloys are the steels. Steels vary both in the way people make them and in their composition. All steels, however, contain small amounts of carbon and manganese and large amounts of iron.

Each variety of steel has certain advantages. *Carbon steels* rank as the most widely used steels. Most carbon steels contain less than 1 percent carbon. Their strength and durability make them popular materials for structural beams, automobile bodies, and food cans. *Alloy steels* contain nickel, chromium, and molybdenum. They are strong enough for such products as bicycle frames and aircraft landing gear. *Stainless steels* contain more than 12 percent chromium, and many varieties also use nickel. Stainless steels can resist *corrosion* (rust and other chemical damage) extremely well. They are common materials for kitchen utensils, pots and pans, and hospital equipment. *Tool steels* are ferrous alloys used to work and shape other materials. They contain such components as tungsten, chromium, and molybdenum. Machines used to shape metal are made with special tool steels that keep their hardness and sharp cutting edges, even when they become red-hot in use.

Alloys for strength and lightness. Many alloys used in vehicles, and especially aircraft, must be strong and light. Aluminum is a common base metal for many of these alloys. Pure aluminum is too light and weak for construction purposes. But manufacturers can mix the metal with other components to make strong, durable, alloys. Some common aluminum alloys contain small amounts of copper, manganese, and magnesium. These alloys are only slightly heavier than pure aluminum and are as strong as some steels. Other aluminum alloys contain zinc, magnesium, and lithium and are even stronger materials. People make aluminum alloys into many different products, including beverage cans, bicycle rims, and house siding.

Magnesium is only about two-thirds as heavy as aluminum. It is not strong enough by itself for most structural purposes, but it serves as the base metal in many useful alloys. Products using magnesium alloys include aircraft and automobile parts, as well as various tools and equipment. Titanium is another base metal for many strong, light alloys. Industries use titanium alloys to make jet engines, aircraft parts, and corrosion-resistant equipment in chemical plants.

Costly and ornamental alloys. People have long used gold and silver as alloys rather than as pure metals. Manufacturers usually add cheaper metals to the gold or silver. This reduces the cost of the alloy while keeping the appearance of the precious metal. Alloying also hardens the gold or silver and keeps it from wearing away rapidly through use. *Yellow gold* is a gold alloy containing copper and silver. It is common in jewelry and other ornamental items. Dentists use similar gold alloys as fillings for teeth. Jewelry and tableware are often made of alloys that contain silver and copper.

Several cheaper alloys make attractive but inexpensive household articles. *German silver* is a blue-white, copper-based alloy containing nickel and zinc. People use German silver for such objects as candlesticks and hardware. *Pewter*, a silver-colored, tin-based alloy, is easy to work and can be highly polished. Plates, mugs, and vases are often made of pewter. Coins are commonly made of copper-nickel alloys.

Other alloys. Among the most common alloys are the brasses. These copper-based alloys contain up to about 40 percent zinc and small amounts of tin, lead, or other elements. Plumbing materials, locks, fasteners, and other hardware are among the many products containing brass. *Monel* is a nickel-copper alloy. Manufacturers often use this alloy for materials that must resist corrosion in sea water, such as pump fittings and boat propellers.

Many alloys have specialized applications. *Stellite*, an extremely hard alloy, consists chiefly of cobalt, chromium, and tungsten. People use stellite as a surface layer on steel to improve its resistance to wear. *Solder*, which has a low melting point, is used to join metal surfaces. *Wood's metal*, another alloy with a low melting point, is employed in fuses for automatic fire alarms and sprinkler systems. *Invar*, an iron-nickel alloy, barely expands or contracts when its temperature changes. It is used in products that must remain at a constant size, such as measuring devices and pendulum rods.

Several alloys make excellent magnets. One example is *Alnico*, a group of alloys containing aluminum, nickel, cobalt, iron, and copper. These alloys can lift up to 60 times their own weight. However, alloys containing large amounts of metallic elements called *rare-earth elements*, such as samarium, produce magnets hundreds of times more powerful than Alnico.

Scientists are developing many alloys that provide greater strength and durability than older alloys. For example, *superalloys* can resist extremely high temperatures and severely corrosive conditions. They contain the base metals nickel or cobalt alloyed with chromium and many other elements. These superalloys are important components of jet engines and spacecraft.

Allport, Gordon W. (1897-1967), was an American psychologist known for his research in human personality. In a series of books and articles published during a period of 30 years, Allport opposed the idea that an individual's personality is a bundle of physiological drives and conditioned responses. Allport emphasized the gradual growth and unfolding of human personality. He believed that a person is not a mechanical product of environmental forces, but a unique force striving to develop his or her own potential.

Gordon Willard Allport was born in Montezuma, Indiana. He graduated from Harvard University in 1919 and received a Ph.D. from Harvard in 1922. From 1930 until his death, Allport taught psychology at Harvard. He helped establish Harvard's department of social relations in 1946. Robert G. Weyant

Allspice is a spice with a flavor similar to that of a combination of cinnamon, cloves, and nutmeg. Allspice is sometimes called *Jamaica pepper*, or *pimento*. It comes from the immature berries of the pimento tree. The berries are gathered by hand, dried in the sun or in a kiln, and ground into powder or sold whole.

People use allspice to season baked goods, fish, liqueurs, pickles, and smoked meats. Oil from the berries is used in making a perfume for soap and to disguise the taste of some medicines. James E. Simon

See also **Pimento**.

Allston, Washington (1779-1843), was one of the first American artists to paint in a Romantic style. He became famous for imaginative, dramatic works, many of which had supernatural themes.

Allston based many of his early paintings on the Bible and other literature. One of his finest early pictures was the Biblical work *The Dead Man Revived by Touching the Bones of the Prophet Elijah* (1813). Allston also painted idealized landscapes. He later abandoned elaborate and dramatic themes and concentrated on simpler subjects, particularly graceful, dreamlike women in dim landscapes. Allston's *Moonlit Landscape* (1819) and other night scenes are noted for their delicate tones. Allston died before completing his last major painting, *Belshazzar's Feast,* which he began in 1817.

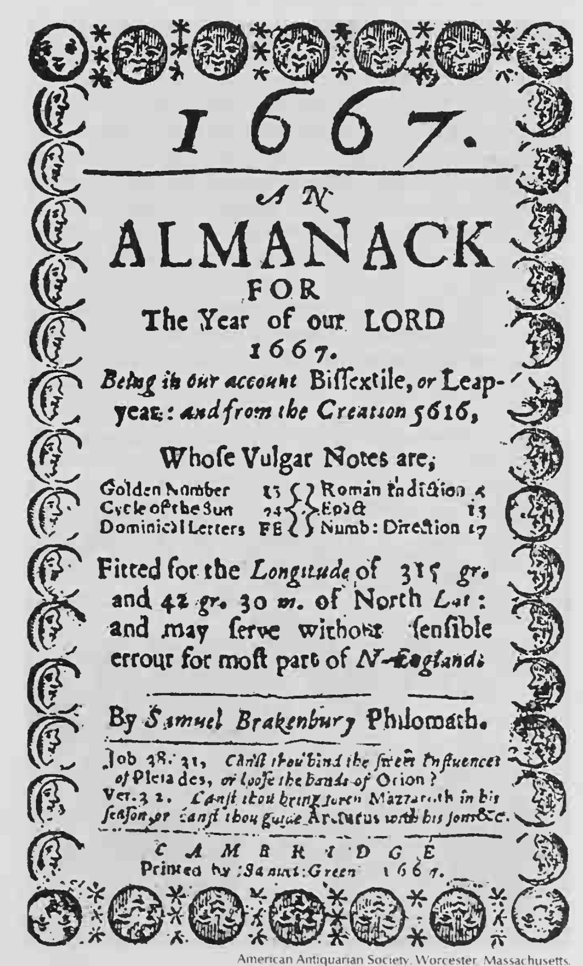
Allston was born in Georgetown County, South Carolina. In 1801, he went to London, where he studied with the American painter Benjamin West. While in Europe, Allston came into contact with English Romantic literature and paintings by Venetian artists of the 1500's that influenced his best work. Allston returned to the United States in 1818. Sarah Burns

Alma-Ata. See **Almaty**.

Alma mater, *AL muh MAH tuhr* or *AHL muh MAH tuhr,* is an expression used by students or graduates to refer to their university or college. The Latin words mean *fostering mother.* The Romans often used the words in speaking of some of their goddesses, such as Ceres and Cybele. The expression was applied to European universities during the Middle Ages, probably first at the University of Bonn in Germany. A statue of the Virgin Mary at Bonn was called *Alma Mater,* or *Beloved Mother.* Thomas J. McLernon

Almanac, *AWL muh nak,* is a book or pamphlet, usually published once a year, that contains many kinds of information. An almanac often includes a calendar, outstanding dates and events, movements of heavenly bodies, and facts about governments, history, geography, and weather. It may also give figures on population, industry, and farm production.

Almanacs originally provided a calendar of the months, with eclipses, the movements of the planets, and the rising and setting times of the sun, moon, and stars. People believed that this information would be useful to farmers and to navigators.



Many scholars believe that the earliest almanacs contained predictions made by ancient Persian astrologers. Later, almanacs appeared in Rome. The oldest existing copies of almanacs today were written in the 1300's and 1400's. Publishers issued almanacs in England in the 1600's to give information about the calendar. These included the *Nautical Almanac,* for sailors.

Almanacs appeared in colonial America in the 1600's. They were usually small pamphlets giving calendars, the dates of religious feasts, weather forecasts, and signs of the zodiac (see **Zodiac**). *Poor Richard's Almanac* was the best known of these early books. Benjamin Franklin first published the almanac for the year 1733. The book had poetry, astronomy information, and lists of court justices and roads. Franklin contributed many *proverbs* (short sayings) that became widely quoted. See **Poor Richard's Almanac**.

In the 1800's, many governments and newspapers began issuing almanacs. These included food recipes, first-aid advice for injuries and snake bite, weather predictions, and *conundrums* (short, humorous questions and answers). Gradually, publishers stopped predicting the weather, except in the *Old Farmer's Almanac,* the *Farmer's Almanac,* and several local almanacs.

Almanacs today, such as *The World Almanac,* contain general information. Almanacs published by groups, such as the United Nations, contain facts, statistics, and documents about many countries. Newspapers, religious groups, business organizations, and certain trades or professions publish almanacs with specialized information.

A book of great value to navigators and astronomers is *The Astronomical Almanac,* published by the United States Naval Observatory. This almanac includes tables and charts about stars, tides, eclipses, latitude, longi-

Almandine. See **Garnet.**

Almaty, *ahl mah TIH* (pop. 1,147,000), also spelled *Alma-Ata,* is the largest city and the economic and cultural center of Kazakhstan. It lies in the southeastern part of the country, in an irrigated valley at the foot of the Tian Shan mountain range. For the location of Almaty, see **Kazakhstan** (map).

Almaty has many treelined boulevards and large parks. It is the home of the Kazakh University and a number of specialized institutes of higher learning. The Medeo sports complex hosts international sports competitions. Industries in Almaty produce food products, metal products, printed material, and textiles.

Almaty was founded in 1854. It was originally called Verny. In 1921, it was renamed Almaty, which means *father of apples.* The name refers to nearby apple orchards. In 1929, Almaty became the capital of Kazakhstan, which was then an autonomous republic of the Soviet Union. It remained the capital after Kazakhstan became an independent country in 1991. In 1997, Akmola (now called Astana) replaced Almaty as the capital.

Nancy Lubin

Almond, *AH muhnd* or *AHL muhnd,* is a delicious nut. The nuts are the seeds of the beautiful almond tree. Each nut grows in a thin shell that looks somewhat like a peach stone. A green leathery hull covers the shell. The hull splits open when the almond is ripe.

Some almond trees produce sweet nuts; others have bitter ones. Sweet almonds are a popular delicacy when toasted, salted, and eaten whole, or added to candies and rich pastries. Bitter almonds are not edible. Growers cultivate bitter almond trees only for the almond's oil, although people also extract oil from the sweet nuts. Oil of bitter almonds contains the poisonous hydrocyanic (prussic) acid (see **Prussic acid**). After the acid is removed, the oil is used in flavoring extracts.

WORLD BOOK illustration by Kate Lloyd Jones, Linden Artist Ltd.

The almond is the seed of the almond tree and a delicious nut. Each nut grows in a shell that resembles a peach stone.

The almond tree is native to southwestern Asia. But today it is widely grown in the countries that border the Mediterranean Sea. The trees also thrive in California, where commercial groves produce large annual crops of almond nuts.

Almond trees are well-proportioned and may grow 40 feet (12 meters) high. They have long, pointed leaves that curl, and showy pink blossoms that reach about 1 $\frac{1}{2}$ inches (3.8 centimeters) across. The blossoms open early in spring, long before the leaves appear. For this reason, almonds are grown commercially only in regions that do not have early spring frosts. In other regions, people grow the trees as ornamentals. Walter S. Judd

Scientific classification. The almond belongs to the rose family, Rosaceae. It is *Prunus dulcis.*

Alnico. See **Alloy** (Other alloys).

Aloe, *AL oh,* is the name of a group of over 200 fleshy-leaved plants native to the Middle East, Madagascar, and southern Africa. They are often cultivated in regions with warm climates. Aloes are related to lilies, though the two differ greatly in appearance.

Aloe plants range in height from a few inches or centimeters to 30 feet (9 meters) or more. The leaves of many species become large. They are lance-shaped and sharp-pointed, with jagged edges that end in sharp hooks. The leaves usually grow directly from the ground in the form of a large rosette. From the center of this rosette springs the flowering stalk that ends in a dense cluster of yellow or reddish tube-shaped flowers. The century plant, also called *American aloe,* is similar in appearance but unrelated.

Farmers in southern Texas raise large quantities of the *Barbados aloe,* also known as *aloe vera.* This species also is a common houseplant. Its leaves contain a bitter juice. Manufacturers heat the juice at low temperatures to produce a powder and a gel. The powder is used as a laxative and as an ingredient in some dietary supplements. Aloe gel is colorless and feels cool on the skin. It is used to make a wide variety of cosmetics, including skin creams, shampoos, and suntan lotions. Research has shown that aloe gel is effective in treating burns and frostbite.

David M. Stone, Photo/Nats

Barbados aloe

Certain African species of aloe have fibers in their leaves that are used for making rope, fishing nets, and coarse cloth. Others have a finer fiber that is used to make lace, and some species are used to make violet dye.

Alwyn H. Gentry

Scientific classification. Aloes are in the lily family, Liliaceae. The Barbados aloe is classified as *Aloe vera* or *A. barbadensis.*

Alpaca, *al PAK uh,* is a grazing animal of South America that is related to the camel. It is raised usually for its

Francisco Erize, Bruce Coleman Ltd

The alpaca is a South American animal valued for its thick, straight hair, which is used to make warm, soft material.

fine wool. Sometimes the young are killed for meat. The alpaca lives in mountain regions of Peru and Bolivia. It thrives at heights from 12,000 to 16,000 feet (3,660 to 4,880 meters) above sea level. The blood of the alpaca is especially efficient in carrying oxygen, which is less abundant at high elevations.

The alpaca resembles the llama. Both of these animals are believed to be descended from the guanaco, a wild animal of the Andes Mountains. The alpaca has longer wool of much better quality than the llama. Alpacas are also close relatives of the wild, wool-bearing vicuñas that live in the Andes.

The alpaca stands a little less than 4 feet (1.2 meters) high at the shoulder. It has a thick coat of black, white, or brown hair that grows from 8 to 24 inches (20 to 61 centimeters) long. This hair is much straighter and finer than sheep's wool. It provides one of the best fibers known for making warm, soft material. Owners usually shear their alpacas every year. They get as much as 7 pounds (3 kilograms) of wool from some of them.

Bolivia and Peru have become the world's most important producers of alpaca wool. They export some of it to the United States and Europe to be manufactured into cloth. They weave the remainder at home and often make shawls out of it. Indians of Peru raised alpacas, and made the wool into cloth for hundreds of years before Europeans came to South America. Much cloth called alpaca actually contains sheep's wool and cotton and has little or no alpaca wool in it. Anne Innis Dagg

Scientific classification. Alpacas belong to the family Camelidae. They are *Lama pacos.*

See also **Guanaco**; **Llama**; **Vicuña**.

Alpenhorn. See Alphorn.

Alpha Centauri, *AL fuh sehn TAWR eye,* is a multiple star system in the constellation Centaurus. It is visible only from the Southern Hemisphere. It consists of three stars that differ in brightness. One of them is Proxima Centauri, the star closest to earth except for the sun. This star lies 4.2 light-years away (see **Light-year**). The other two stars, Alpha Centauri A and Alpha Centauri B, are a *binary system,* a pair of closely spaced stars that orbit each other. They are about 4.4 light-years from the earth. The brightest of the three stars is Alpha Centauri A, which has an apparent magnitude of 0.01. The apparent magnitude of Alpha Centauri B is 1.34, and Proxima Centauri's is 11.09 (see **Star** [Brightness of stars]). Alpha Centauri is approaching our solar system at about 14 miles (23 kilometers) per second. Sumner Starrfield

Alpha Orionis. See Betelgeuse.

Alpha particle is an atomic nucleus that consists of two protons and two neutrons. An alpha particle can become the nucleus of a helium atom by capturing two electrons.

Two processes create alpha particles—(1) *radioactive decay* and (2) *nuclear fusion.* In the decay process, a larger nucleus *emits* (gives off) an alpha particle. For example, nuclei of heavy chemical elements, such as uranium and thorium, decay by emitting alpha particles. Almost all the helium on earth formed by radioactive decay.

In the fusion process, hydrogen atoms *fuse* (join) to create alpha particles. The amount of helium measured in stars and galaxies agrees with the big bang theory of the beginning of the universe. In that theory, most of the helium in the universe was produced by nuclear fusion within the first thousand seconds of the big bang.

Fusion also creates alpha particles inside stars. For example, a series of fusion reactions produces most of the sun's energy. These reactions consume four protons and make one alpha particle; a single proton is the same as the nucleus of the simplest form of hydrogen. The alpha particle has less matter than the protons had. The missing matter is converted to energy. William Karl Pitts

See also **Big bang**; **Helium**; **Radiation** (Sources of radiation); **Star** (Fusion in stars).

Alpha Scorpii. See Antares.

Alphabet is the series of letters used in writing a language. The word comes from *alpha* and *beta,* the first two letters of the Greek alphabet. Another name for the 26 letters of our alphabet is the ABC's.

Most books, magazines, and newspapers are printed in the 26-letter alphabet called *Roman.* But the Romans did not invent it. They put finishing touches on a system that had been growing for thousands of years. See the articles on each letter of the English alphabet at the beginning of each letter in *The World Book Encyclopedia.*

The earliest writing

In early times, people could communicate with one another only by speaking or by making gestures. They had no way to keep records of important events, unless they memorized the story of a great battle or important happening. They had no way to send messages over long distances unless they passed them from one person to the next by word of mouth, or had one person memorize the message and then deliver it.

The first stage in writing came when people learned to draw pictures to express their ideas. In *ideography,* each picture conveyed an idea. Ideography enabled even people who did not speak the same language to communicate with each other. Then people learned *logography,* expressing ideas indirectly by using signs to stand for the words of the idea. Instead of drawing pictures of five sheep to show a herd of five animals, a person could draw one sign for the numeral "five" and one

for "sheep." Gradually people learned to use a *syllabic* system, in which a sign that stood for one word could be used not only for that word but also for any phonetic combination that sounded like that word. This is what we call *rebus writing* (see **Rebus**). If we used rebus writing in English, we could draw a sign for the word "bee" followed by a sign for the word "leaf" to stand for the word "belief." Finally, people developed alphabets in which individual signs stood for particular sounds. Today, most written languages in the world use alphabetic writing systems. For more information, see **Writing**.

The earliest alphabets

The Egyptians used a system of several hundred signs that stood for full words or for syllables. They could write the word *nefer*, or *good*, with a single sign for the whole word, or with three signs, for the sounds *n*, *f*, and *r*. These signs specified the consonants in syllables, but not the vowels. Egyptian writing, which developed around 3000 B.C., was formally a picture writing, and structurally a word and syllabic writing.

The Semites, who lived in Syria and Palestine, knew something of the Egyptian writing system. They worked out an alphabetic writing about 1500 B.C. They used signs to show the consonants of syllables, just as the Egyptians did. The Semites seem to have adapted some of the pictures from Egyptian hieroglyphics, but they used these symbols for sounds in their own language. The oldest known Semitic alphabets have been found in Syria and at a Semitic outpost in the Sinai peninsula.

The Phoenicians, who lived along the coast of the Mediterranean Sea, developed a system of 22 signs about 1000 B.C. Their alphabet was structurally related to Semitic and Egyptian, with signs for consonant sounds, not vowel sounds. Early Phoenician writing con-

Development of the English alphabet

The English alphabet developed from a number of early writing systems, beginning with the sign writing of Ancient Egypt. The Romans had given most capital letters their modern form by A.D. 114. But the letters *J*, *U*, and *W* were not added to the alphabet until the Middle Ages.

The alphabets of five languages are shown above. Hindi is India's most widely spoken language. People throughout the Middle East and northern Africa use Arabic, which is read from right to left. Gaelic, along with English, is the official language of Ireland.

sists partly of pictographic forms, which they may have borrowed from older pictographic systems, and partly of geometric or diagrammatic signs that they invented. Historians find it difficult to trace the formal relations between Semitic and Phoenician signs, because Phoenician has both pictographic and diagrammatic signs, and because so little is known of the ancient systems used in Syria and Palestine.

The Cypriots, the people of the island of Cyprus, developed an alphabet of their own. Starting with an unknown word-syllable system, they worked out an alphabet of 56 signs, each standing for an initial consonant and a different vowel. The next step was to create separate signs for vowels and consonants.

The Greeks came in contact with Phoenician traders, and learned from them the idea of writing individual sounds of the language. Sometime during the period before 800 B.C., they borrowed Phoenician symbols and modified them to form the Greek alphabet. The Phoenician alphabet included more consonants than the Greeks needed for their language, so they used the extra signs for vowel sounds. In this way, the Greeks improved on both Phoenician and Cypriot ideas, because they could combine individual letters for both consonants and vowels to spell any word they wanted.

The Greeks took over the Phoenician names for their signs, and in most cases the signs themselves. The first letter of the Phoenician alphabet, 𐤀, and its name, *aleph,* meaning *ox,* became Α, or *alpha* in Greek. The second letter, 𐤁, or *beth,* meaning *house,* became Β, or *beta* in Greek. The Greeks later modified the shapes of these letters, adding and dropping some letters, to form the 24-letter Greek alphabet of today.

The Roman alphabet

The Etruscans moved to central Italy from somewhere in the eastern Mediterranean region sometime after 1000 B.C. They carried the Greek alphabet with them. The Romans learned the alphabet from the Etruscans, and gave it much the same form we use today. The early Roman alphabet had about 20 letters, and gradually gained 3 more.

Capital letters were the only forms used for hundreds of years. Many people consider the Roman alphabet perfected by A.D. 114. That year, sculptors carved the inscriptions on a memorial column built to honor the emperor Trajan. The style of lettering they used is considered one of the most beautiful in the world.

Carving letters in stone is not an easy job, and Roman stonecutters rounded or squared, simplified, and polished their letters. They developed the beautiful thick-and-thin strokes we use today. They also added *serifs* (little finishing strokes) at the tops and bottoms of many letters. The practical reason for serifs was that the carvers found it difficult to end wide strokes without ugly blunt lines. And if a chisel slipped while squaring off an end, they could not erase the mistake. But serifs also added a touch of strength and grace to Roman lettering, and are still used today.

Small letters gradually developed from capitals. Scribes who copied books often used *uncials* (rounded letters) that were easier to form than some capitals. True lower-case letters developed later, when scribes saved space in books by using the smaller letters.

The alphabet today is not well suited to writing words in English. It does not have a separate character for every distinctive sound in English, and it has several characters with more than one sound. Many other languages written with Roman letters use accent marks to show changes in sounds. Linguists use an almost perfect alphabet, the International Phonetic Alphabet, which has more than 80 characters (see Phonetics).

Other systems of writing

Arabic and Hebrew, as well as Sanskrit and many alphabets used in various parts of India, developed from the Phoenician system. Arabic and Hebrew were influenced by the Aramaic alphabet and vocabulary.

The Cyrillic alphabet. In the 800's, Saints Cyril and Methodius, two brothers, invented the Glagolithic alphabet while serving as missionaries among the Slavic peoples. They based this alphabet on Greek and on a Slavic language called Macedo-Bulgarian. About 900, the Glagolithic alphabet was modified into the Cyrillic alphabet, which was named for Cyril, the more literary of the brothers. Missionaries from Constantinople (now Istanbul) carried the Cyrillic alphabet with them when they converted the Russians, Serbs, Bulgars, and other Slavic peoples. Missionaries from Rome used the Roman alphabet when they converted the Poles and Czechs. They made spelling changes and used accent marks for special sounds. Serbs and Croats speak

Serbo-Croatian. But Serbs write with the Cyrillic or the Roman alphabet, and Croats use the Roman alphabet.

Chinese is the only major language that does not have an alphabetical system of writing. Chinese has thousands of characters that stand for words. Most characters are derived from pictographs of objects. Others are combinations of pictographs used to form abstract words. Still others have no pictographic background at all. Some Chinese characters can be used to express the syllables of proper names or foreign words.

Japanese is based on Chinese, but the characters represent either syllables or words. Most of the Japanese characters are taken directly from Chinese, because Japanese scholars copied the forms, as well as the structure, of the Chinese language. Marianne Cooley

Alphonsus Liguori, *al FAHN suhs lee GWAW ree,* **Saint** (1696-1787), an Italian religious teacher, founded in 1732 the Congregation of the Most Holy Redeemer (the Redemptorist Order) for religious work among poor people in rural areas. He wrote books on moral problems and for devotional and doctrinal purposes. He emphasized the power of prayer. Alphonsus Liguori also composed many popular hymns. He was born near Naples, Italy. He was *canonized* (proclaimed a saint) in 1839. His feast day is August 2. Marvin R. O'Connell

Alphorn, also called *alpenhorn,* is a long tube-shaped instrument used chiefly by herders to call cattle in mountain regions of Switzerland. It is made of long wooden staves tightly bound together with birchbark strips to form an airtight tube. Alphorns are from 7 to 12 feet (2.1 to 3.7 meters) long. Their crude construction causes certain irregularities of pitch. The alphorn is played with a cup-shaped wooden mouthpiece. Gioacchino Rossini included an alphorn in his opera *William Tell* (1829). The alphorn has been used since prehistoric times. Melvin Berger

Swiss National Tourist Office

The alphorn is a long, tube-shaped musical instrument used in Switzerland and other mountainous countries.

Alpinism. See Mountain climbing.

Alps are the largest mountain system in Europe. The snow-capped peaks and sheltered, peaceful valleys of the Alps are among Europe's most spectacular sights.

The Alps stretch across south-central Europe in a broad arc. The mountains begin near the Mediterranean Sea and form a border between France and Italy. The Alps then extend northward and eastward through northern Italy, Switzerland, Liechtenstein, southern Germany, Austria, and Slovenia. The mountains form a chain about 660 miles (1,060 kilometers) long and cover an area of about 80,000 square miles (210,000 square kilometers). The broadest part of the Alps is about 160 miles (260 kilometers) wide and extends across Switzerland between Germany and Italy. The highest Alpine peak, Mont Blanc, rises 15,771 feet (4,807 meters) on the border between France, Italy, and Switzerland. Other famous mountains in the Alps include Monte Rosa, which rises 15,203 feet (4,634 meters), and the Matterhorn, which reaches 14,692 feet (4,478 meters). Both stand on the Swiss-Italian border.

The Alps form a major barrier between central and southern Europe. Few people made the difficult trip through the mountains until the Romans gained control of the Alps between 58 and 15 B.C. and built roads through several Alpine passes. The roads allowed communication and trade between the peoples on either side of the Alps. Today, modern railroads and highways enable people to travel easily through the mountains. People come to view the magnificent scenery and take part in such sports as mountain climbing and skiing.

How the Alps were formed. Geologists believe a large sea once covered what is now the Alpine region. More than 100 million years ago, the land masses north and south of this sea began to move closer together. The great pressure placed on the seabed forced it to gradually fold so that great ridges and valleys formed. Rock that once lay deep below the seabed was pushed to the top of ridges. The highest parts of the Alps include such rocks as gneiss, granite, and schist, which were formed by heat and pressure deep within the earth. Many Alpine ranges consist chiefly of limestone that also formed in the seabed. Most of the Alps had taken shape by about 15 million years ago.

Glaciers occupied valleys high in the Alps from about 2 million years ago until about 10,000 years ago. As these glaciers moved downhill, they gouged the earth and rock, creating U-shaped valleys. Other geologic features visible in the Alps include *cirques* and *cols.* Cirques are bowl-shaped hollows near the peak of a mountain. A col is a high pass between two cirques. A *hanging valley* is a small valley that empties into a larger and lower valley. A stream flowing through a hanging valley may create a waterfall.

The Alpine glaciers also moved earth and rock that had collected along the edges and top of the ice. As the ice melted, rock debris piled up along the glacier's path in bands called *moraines.* Some of these moraines

Peter Baker

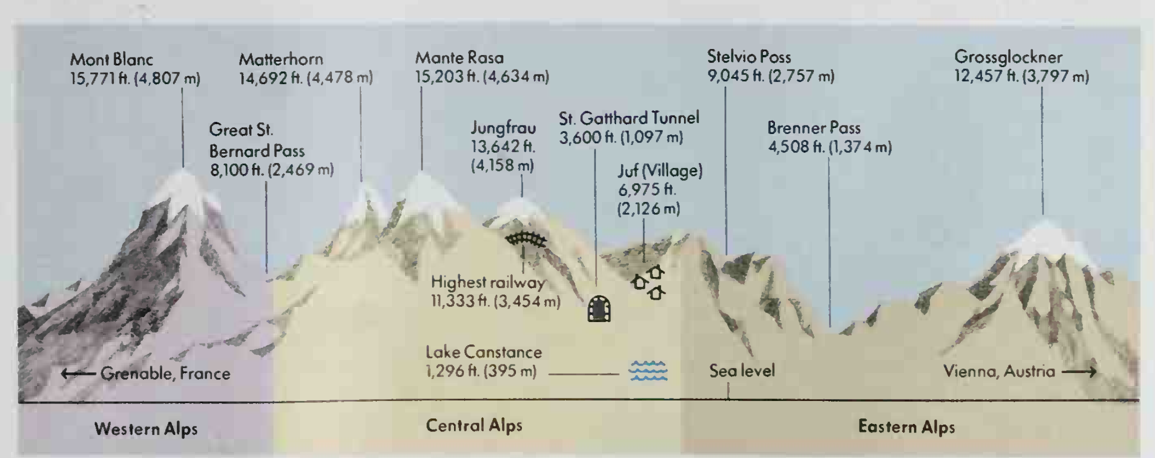
Three famous Alpine peaks—the Eiger, the Mönch, and the Jungfrau, *left to right*—form part of the majestic Bernese Alps in southern Switzerland. Glaciers lie near the mountaintops.

formed natural dams across valleys, creating lakes as water collected behind the dam. Such Alpine lakes as the Lake of Lucerne and Lakes Como, Maggiore, Geneva, Constance, and Zurich were created by this process. Today, there are about 1,300 small glaciers in the Alps. The largest, the Aletsch Glacier, is in southern Switzerland. See **Glacier; Moraine.**

Chief ranges of the Alps. Most geographers divide the Alpine region into the western, central, and eastern Alps. The western Alps include the ranges west of the Great St. Bernard Pass, which is between northwest Italy and southwest Switzerland. The Savoy, Dauphine, Graian, Cottian, Ligurian, and Maritime Alps are considered western Alps. The central Alps lie between the Great St. Bernard Pass and Lake Constance. They include the Bernese, Pennine, Lepontine, and Rhaetian Alps. The central and western Alps are higher and narrower than the eastern Alps. The eastern Alps begin southeast of Lake Constance and consist of the Bavarian, Noric, and Carnic Alps; Hohe and Niedere Tauern; the Dolomites; and the Julian and Karawanken Alps.

Climate of the Alps varies from place to place. In general, the Alps have a *highlands climate.* Such a climate is generally cooler and wetter than that of surrounding areas and is affected by altitude. For example, the higher areas of a mountain range are colder. This results in greater precipitation because cold air cannot hold as much moisture as warm air.

The Alps separate two distinct climatic regions. The land to the south of the Alps has hot, dry summers and mild, moist winters. The land to the north and to the west has a temperate climate with warm summers, cold winters, and precipitation at all times of the year.



The Alps frequently experience warm, dry, violent winds, called *foehns,* that blow downward along mountain slopes. These winds melt snow and ice on the mountainsides, frequently causing avalanches.

Plant and animal life. Various kinds of vegetation grow at different elevations in the Alps. The valleys at the base of the Alps are filled mainly with grass. Beech and oak trees grow on the lower slopes. Fir, pine, and spruce trees cover the higher slopes. Above the *timber line,* the elevation above which trees cannot grow, are Alpine meadows. Mosses, lichens, bare rock, and ice and snow cover the highest elevations of the Alps.

Many species of animals live in Alpine forests and meadows. They include the graceful chamois, which resembles the antelope; and the ibex, a rare, long-horned wild goat. Golden eagles and peregrine falcons live among the highest peaks.

Agriculture and industry. Most farming is done in the valleys and on the sunny lower slopes of the Alps. Small family-owned farms are most common. The chief crops include such grains as barley, oats, and rye. Traditional Alpine farmers raise cattle, goats, and sheep. Dairy farming is also an important economic activity.

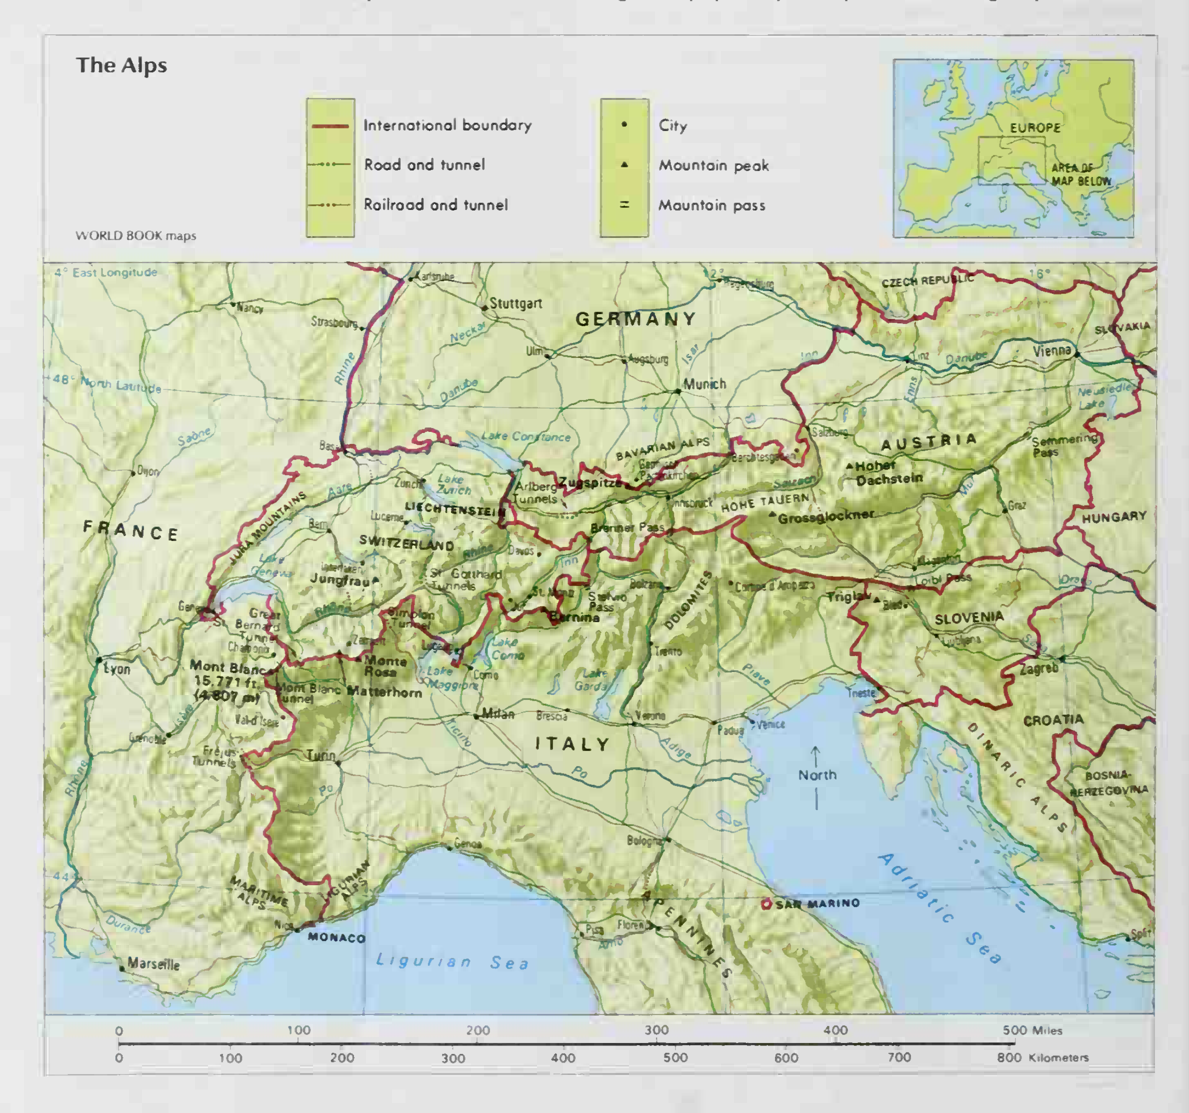
A variety of industries operate in the foothills and valleys of the Alps. Factories manufacture chemicals, electrical machinery, and other equipment. Traditional

WORLD BOOK diagram by George Suyeoka

Some features of the Alps are shown in the above illustration. Most of these features are in the mountain ranges that include Italy's border with Austria, France, or Switzerland. Lake Constance lies in both Switzerland and Germany. The measurements show height above sea level.

handicrafts still produced in the region include shoes and other leather goods, textiles, and ceramics.

Natural resources found in the Alps include bauxite, iron ore, stone, and timber. Many factories run on hydroelectric power that is generated by waterfalls in the mountains. Hydroelectricity also powers most railroads in the region. Power plants in the Alps transmit some electricity to other parts of Europe.



Tourism is important to the economy of the Alps. Well-known Alpine resort communities include Chamonix in France, Lucerne and St. Moritz in Switzerland, Berchtesgaden in Germany, Cortina d'Ampezzo in Italy, and Innsbruck and Salzburg in Austria.

Alpine travel. More than 40 passes occur naturally in the Alps. Highways and railroads have been built through many of them. The Brenner Pass, 4,508 feet (1,374 meters) high, is the most widely used pass in the eastern Alps. It lies between western Austria and northern Italy and has both a major highway and railroad.

In addition, tunnels have been built through the mountains beneath several of the passes. The St. Gotthard Road Tunnel in south-central Switzerland is 10.1 miles (16.3 kilometers) long and is one of the longest highway tunnels in the world. It is part of the St. Gotthard Road, the most-traveled route through the central Alps running between western Germany and Italy. The Simplon Tunnel is the longest railroad tunnel in the Alps. It extends for 12.3 miles (19.8 kilometers) between Switzerland and northwest Italy. The Great St. Bernard Tunnel was the first major highway tunnel to connect Italy and Switzerland. The Fréjus Railway Tunnel and the Mont Blanc Road Tunnel link France and Italy.

Climbing the Alps. Few people attempted mountaineering in the Alps until the 1700's, when scientists began to study the landforms and the biology of the region. In 1786, two Frenchmen, physician Michel G. Paccard and his guide, Jacques Balmat, became the first to reach the top of Mont Blanc. They recorded scientific observations along the way.

Many of the Alpine peaks were climbed for the first time during the mid-1800's, when mountaineering gained popularity as a sport. In 1855, a group of Swiss

and British men made the first successful climb to the top of Monte Rosa. In 1865, climbers reached the top of the Matterhorn for the first time. Most Alpine summits had been conquered by 1900. Mountain climbing in the Alps became even more popular in the 1900's. Today, professional guides use modern equipment to help people scale the highest peaks. Each year, more than 2,000 people climb to the top of the Matterhorn.

History. People have lived in the Alps for thousands of years. By the 500's B.C., Celtic tribes controlled much of the region. From 58 to 15 B.C., the Romans conquered the Alpine Celts. The Romans built roads through various Alpine passes to link Rome with its northern provinces. The roads enabled the Romans to expand their influence into parts of northern Europe. These roads came to rank among the busiest in Europe due to Roman trade with the north.

Travel in the Alps decreased after the Roman Empire collapsed in western Europe during the A.D. 400's. But merchants, government officials, religious leaders, and soldiers continued to use Roman roadways to cross the mountains. Through the centuries, the Alpine region came under the control of a number of empires and states. For more information on the region's political history, see the *History* section of the *World Book* article on each Alpine country.

In the late 1800's, the first railroads crossed the Alps. This service led to the rapid growth of tourism in the region. Today, travelers can cross the Alps in under eight hours by highway or train. Trans-Alpine routes have increased trade among the Alpine countries and between northern and southern Europe. But environmental pollution and overdevelopment caused by growth in highway traffic and tourism are a concern. Howell C. Lloyd

Alsace-Lorraine, *AL sas loh RAYN,* is a region in northeastern France, on the French-German border. It covers 12,289 square miles (31,828 square kilometers). Switzerland lies to the south, and Luxembourg to the north. The map with this article shows that the region looks like a figure "7." Alsace, the north-south arm, has two *departments* (administrative districts)—Haut-Rhin and Bas-Rhin. Lorraine forms the east-west arm. It is divided into the departments of Moselle, Meurthe-et-Moselle, Meuse, and Vosges.

About 4 million people live in Alsace-Lorraine. Most of them belong to the Roman Catholic Church. For hundreds of years, the inhabitants have been part German and part French. Important products of the region include barley, oats, rye, textiles, wheat, and wine. Mineral products include iron ore from Lorraine and potash from Alsace. The Vosges Mountains district of the west supplies timber, coal, and salt; and the streams of this district provide hydroelectric power. Alsace-Lorraine also supports an important automobile industry.

Alsace-Lorraine is a historical region in France.

Alsace and Lorraine were often a prize in wars between France and Germany. In the A.D. 300's and 400's, Teutonic bands drove out the Celtic tribes then living in the region. In the late 700's, the area became part of Charlemagne's empire. It fell to the middle kingdom between France and Germany when Charlemagne's grandsons divided the empire. But before long Alsace and Lorraine came under German rule.

Alsace and Lorraine remained under German rule until the 1500's, when France gained control of them by slow stages. The people fought efforts to turn them into French people. But the French Revolution of 1789 brought a change of heart. The Alsatian people became so French in spirit that more than 50,000 moved to France when Germany got almost all of Alsace in 1871.

The Germans resented the loss of Alsace-Lorraine after World War I (1914-1918). They regained control of the area in World War II (1939-1945). The Germans moved thousands of the people out of the region and replaced them with Germans, Poles, and Russians. The Allies drove the Germans out of Alsace-Lorraine in 1944-1945, and France again took control of the region.
William M. Reddy

Alsatian dog, *al SAY shuhn,* is the term used in Britain and Commonwealth countries for a German shepherd dog. See German shepherd dog.

Altai Mountains, *AL ty,* form a lofty range that runs about 1,200 miles (1,900 kilometers) northwest across the borders of western Mongolia and Kazakhstan. For location, see China (terrain map). The Altai are among

the oldest mountains in Asia. They contain rich deposits of copper, gold, iron, lead, silver, and zinc. Some have pastureland and forests. The highest peak is Belukha, or White Mountain (14,783 feet, or 4,506 meters).

James A. Hafner

Altar is a raised place or object that serves as the central point of religious worship. An altar may be as simple as a mound of earth or as elaborate as a carved stone table. Altars may be outdoors, in homes, or in buildings of public worship. The word *altar* probably comes from the Latin word *altus,* which means *high place.*

The ancient Greeks, Romans, and Israelites used altars to burn incense and to sacrifice animals or other offerings to a god or gods. Christians adopted the idea of an altar for sacrificial worship by the A.D. 100's. By the Middle Ages, Christian altars had been moved from a more central position in the church to the back wall. The priest stood at the altar, with his back to the worshipers. In 1964, the Roman Catholic Church issued a directive that altars be moved away from the back wall of the church so that the priest could face the congregation. In Eastern Orthodox Churches, the altar is behind a screen called an *iconostasis.* In the 1500's, many Protestants converted altars into simple tables on which the sacrament of the Lord's Supper is celebrated. Jill Raitt

Richard Kehrwald, Black Star

An altar is the central point of worship services in many religions throughout the world. The priests shown above celebrate Mass behind a tablelike altar in a Roman Catholic church.

For pictures of an altar, see **Religion** (The Mass; Confucius' birthday); **Hinduism; Buddhism** (Buddhist monks).

Alternating current. See **Electric current; Electric generator; Tesla, Nikola.**

Alternation of generations is a term that describes the life cycle of most plants and some algae. The term *generations* is misleading since it refers to two different phases that make up a single life cycle.

In one phase, the plant is known as a *gametophyte* or *gamete-bearing plant* and produces sex cells called *gametes.* Gametophytes can produce male sperm cells, female egg cells, or both. When a sperm cell and an egg cell unite, they form a *zygote* (fertilized egg). The zygote develops into the next phase of the reproductive cycle. In this phase, the plant is known as a *sporophyte* or *spore-bearing plant* and produces reproductive cells called *spores.* Then spores develop into gamete-producing plants, and the cycle begins again.

In most plants, the gametophyte and the sporophyte differ in size and appearance. For example, the phase that people recognize in ferns is the sporophyte. The familiar phase of mosses is the gametophyte. The sporophyte is the familiar phase of all flowering and cone-bearing plants. Joseph E. Armstrong

Alternative medicine refers to a wide range of healing practices that generally are not considered part of conventional medicine. In general, practitioners of alternative medicine use natural remedies and believe that the body can heal itself if given a chance. They feel that "invasive" treatments, such as drugs and surgery, should only be used as a last resort.

Some forms of alternative medicine—such as acupuncture, chiropractic, and *naturopathy* (use of natural agents, such as fresh air, massage, and exercise)—are well-established professions with standard training and licensing of practitioners. Other forms are less organized as professions. These include *herbalism* (use of remedies derived from plants) and *homeopathy* (use of minute amounts of substances that, in a healthy person, produce the same symptoms as those of the disorder). Still other forms of alternative medicine—including faith healing and psychic healing—are even further removed from the world of scientific and professional medicine.

During the second half of the 1900's, growing numbers of people became disillusioned with conventional medicine, particularly its expense, risks, and inability to cure certain common serious diseases. Many patients complain that conventional doctors too readily prescribe drugs as treatment. Others complain that conventional medicine is too impersonal—that it focuses on the disorder rather than the patient. Such disillusioned patients often seek out alternative practitioners.

Most doctors have regarded alternative medicine as unscientific. But an increasing number of doctors are trying to combine the best ideas and practices of both conventional and alternative medicine. This use of alternative medicine as a potentially helpful supplement to conventional treatments is often called *complementary and alternative medicine.* Andrew Weil

Alternative school is any public or private school that differs from traditional schools in curriculum, purpose, or teaching methods. Most alternative schools attempt to establish a less formal relationship between pupils and teachers. They also try to make greater use of community facilities outside the school and to involve parents in the educational process. Alternative schools developed because of dissatisfaction with the quality and aims of traditional schools.

Alternative schools have voluntary enrollments. A typical alternative school has 30 to 40 students. A school of this size can easily adjust its program to fit individual needs and desires. Some alternative schools work only with children of elementary-school age. Others accept only teen-agers. Many alternative schools put students of several ages into classes based on subject interest.

Many alternative schools in the United States operate independently of the public school system. These schools, which are privately run, are usually called *free*

schools. The word *free* refers to the independence of such schools. It also describes the emphasis of the schools in allowing students to make their own decisions. Other alternative schools operate as part of the public school system. Such schools may be in one area of a public school building or in a separate building provided by the school system. The separate buildings are often called *magnet schools* or *specialty schools.* They attempt to attract students from a wider attendance area than a traditional neighborhood school.

Features of alternative schools

The basic principle followed by alternative schools is that not all children have the same goals and the same ways of learning. Many of the people involved in operating these schools do not want to convert the whole school system to their methods. They want to provide the opportunity for a different kind of education for children who would benefit from it.

The major feature of many alternative schools is the *open space classroom,* sometimes called an *open classroom.* The teacher of an open space classroom, instead of lecturing most of the time, helps students find interesting ways to learn on their own. Many kinds of educational materials are kept in the classroom. The students work with these materials alone or in groups. The teacher gives the students individual help.

Most alternative schools lack adequate funds and such facilities as gymnasiums, laboratories, and shops. Parents and volunteers provide most of the finances, help run the classes, and help maintain the buildings.

Many forms of alternative schools have developed in response to various needs. *Street academies* and *dropout centers,* which function in the poor sections of big cities, help high school dropouts continue their education. *Storefront schools* have developed from child-care and kindergarten facilities. *Work schools* hold classes part of the day, and the students work at regular jobs the rest of the day.

The *school without walls* plan, used in some large cities, takes advantage of the educational opportunities provided by businesses and institutions of the community. Students may spend part of the day at an artist's studio, a factory, a museum, a newspaper office, a repair shop, a theater, or a government or private agency. The purpose of this method is to make learning more realistic and enjoyable, and to broaden the experiences offered high school students.

Some alternative schools emphasize the study of the culture and history of a certain minority group. Some accept only students from one such group. Others seek students from several cultures and ethnic groups.

A number of alternative schools have been designed for children from middle- or upper-class families. Usually such schools are in suburban or rural areas. Most of them stress the independence of each student and have no required subjects.

A trend in the development of alternative schools has been the establishment of such schools within the public school system. One plan offers a variety of learning environments from which students, parents, and teachers may choose. At the elementary school level, parents can choose to place their children in a traditional classroom or in one of several kinds of open space classrooms. High school students decide whether to enter a free school with few course requirements, or one of several programs in the regular high school program.

History

Experimental schools similar to alternative schools have been set up throughout the history of public education. But the term *alternative school* first came into widespread use during the 1960's. It referred to a wide variety of programs and institutions that differed greatly from private schools and special programs within public schools. Most private schools had been established for the children of wealthy families. Most special programs worked only with students who had special problems or exceptional ability. But most alternative schools welcomed any student.

African Americans in the Southern States set up some of the first alternative schools. During the 1960's, these people established *freedom schools* in communities where public schools refused to admit their children. In many Northern cities, African Americans set up alternative schools because of dissatisfaction with the treatment of their children in public schools.

Many people began to realize that a public school system could hurt, rather than help, some children. They declared that parents and educators should have the freedom to set up alternative education methods.

During the late 1960's, several groups created open space classrooms modeled on the United Kingdom's *infant schools.* Such schools are attended by children from age 5 to 7. In the United States, similar classrooms were set up in a number of public schools. Their success contributed to the growth of the alternative school movement. Beatrice Gross and Ronald Gross

Alternator. See Electric generator.

Altgeld, John Peter (1847-1902), was a reformer who served as governor of Illinois from 1893 to 1897. Under his leadership, Illinois established a board to help settle strikes, gave prisoners the right to parole and probation, and also improved its public school system.

Shortly after taking office, Altgeld, a Democrat, pardoned three of the men who had been convicted of a bombing during the Haymarket Riot (see **Haymarket Riot**). He believed they had not received a fair trial. However, he was widely criticized for his action.

In 1894, President Grover Cleveland sent federal troops to Chicago during the Pullman Strike (see **Pullman Strike**). Altgeld opposed what he considered interference in a state matter. He protested to Cleveland but again received wide criticism.

Altgeld was born in Niederselters, Germany, near Wiesbaden. His family settled in the United States in 1848. Altgeld became a lawyer in 1871 and served as a superior court judge in Cook County, Illinois, from 1886 to 1891. His book *Our Penal Machinery and Its Victims* (1884) criticized the U.S. court system for discriminating against the poor. Clyde C. Walton

Altimeter, *al TIHM uh tuhr* or *AL tuh MEE tuhr,* is an instrument that measures altitude. Aircraft and some satellites are equipped with altimeters. Mountain climbers, surveyors, and scientists also use altimeters.

There are three main kinds of altimeters: (1) pressure altimeters, (2) radar altimeters, and (3) laser altimeters. Pressure altimeters are standard equipment on aircraft. Some planes also carry radar altimeters. Earth satellites carry radar and laser altimeters to measure the height of the oceans, land, and icecaps. Scientists have used radar and laser altimeters mounted on space probes to map the surfaces of other planets and the moon.

A pressure altimeter resembles a type of gauge known as an *aneroid barometer.* Both devices measure the effect of air pressure on a metal chamber from which most of the air has been removed. A pressure altimeter determines an aircraft's distance above sea level by measuring the pressure of Earth's atmosphere. This pressure decreases as altitude increases.

A radar altimeter measures the time a radio signal takes to travel from a plane or satellite to Earth's surface and back. A laser altimeter works in the same way, but uses pulses of laser light rather than radio waves.

To use a satellite-based altimeter to measure the height of features on Earth's surface, scientists must first measure the satellite's distance above sea level. They do this by tracking the satellite by lasers and radio from ground-based stations and from satellites of the Global Positioning System (GPS). The GPS is a worldwide navigation system that uses radio signals broadcast by satellites. The altitudes of the ground stations and the GPS satellites are precisely known. Thus, scientists can use those altitudes and the tracking data to determine a satellite's distance above sea level.

Researchers have used measurements from satellite-based altimeters to determine how the ocean shrinks and expands as its temperature changes. They have also used satellite data to measure the speed and direction of ocean currents. In addition, satellite-based altimeters have measured the height of the icecaps covering large areas of land in the polar regions. Researchers can use the information about the icecaps to determine whether the caps are growing or shrinking. George H. Born

See also Barometer; Global Positioning System.

Altitude is the height of an object above the surface of Earth, the moon, or some other reference body. In geography, the height of a physical feature or place is commonly called elevation. In astronomy, altitude is the angle between a line from an observer to, for example, a star and a line from the observer to the horizon. See also Air; Altimeter; Mountain; Navigation.

Altitude record. See Balloon (History); Glider (table).

Altman, Robert (1925-), is an American motion-picture director known for his unusual, offbeat films. His movies have a documentary visual style that seems as if the camera just happened to catch revealing moments in the characters' lives. He prefers ensemble casts, with many equally important performers, rather than casts dominated by a few stars. His films tend to favor character analysis over plot. They reflect an ironic skepticism toward traditional American values and institutions. Many of his films have pessimistic, unhappy endings, though they use eccentric humor and raunchy comedy.

Altman was born on Feb. 20, 1925, in Kansas City, Missouri. He began his career directing industrial films and then TV in the 1950's. He gained prominence when he directed *M*A*S*H* (1970), a darkly comic movie about a battlefield hospital. In the 1970's, he directed a series of offbeat films praised by critics, including *McCabe and Mrs. Miller* (1971), a quirky Western; *Thieves Like Us* (1974), a rural gangster film; and *Nashville* (1975), about the country music industry. His output fell in the 1980's, but he made a comeback in the 1990's with *The Player* (1992), a satire on the movie industry; *Short Cuts* (1993), based on stories by the American author Raymond Carver; *Kansas City* (1996), set during the Great Depression; and *Cookie's Fortune* (1999), a comedy about eccentric characters in Mississippi. *Dr. T & and the Women* (2000) portrays the personal and professional life of a *gynecologist* (women's doctor). Altman's other films include *Brewster McCloud* (1971), *California Split* (1974), *Popeye* (1980), *Fool for Love* (1985), *The Gingerbread Man* (1998), and *Gosford Park* (2001). Louis Giannetti

Altrusa International is a volunteer organization of business and professional leaders who work to improve their communities through personal service. Altrusa operates programs in international relations, vocational guidance, and the promotion of literacy. It also sponsors youth groups and runs a charitable foundation. About 17,000 members belong to 550 clubs in the United States, Canada, Bermuda, Chile, El Salvador, Guatemala, India, Ireland, Mexico, New Zealand, the Philippines, Puerto Rico, South Korea, and the United Kingdom. Altrusa International was founded in 1917. Its headquarters are in Chicago. Critically reviewed by Altrusa International

Alum, *AL uhm,* is the name of a group of double salts. Double salts consist of two simple salts that form crystals together in fixed amounts. Common alum is a double salt of *hydrated* (water-containing) potassium sulfate and aluminum sulfate. It is also called potash alum or potassium alum. Its formula is $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$. Other alums are ammonium alum, sodium alum, and potassium chrome alum. Most are manufactured from *bauxite* (aluminum oxide ore). Potassium alum helps stop bleeding and shrinks human or animal tissues. Alums are used to make glue, dyes, baking powder, and leather tanning agents; to purify water; and to harden plaster of Paris. See also Salt, Chemical. Marianna A. Busch

Alumina, *uh LOO muh nuh,* also called *aluminum oxide,* is a compound composed of aluminum and oxygen. It has the chemical formula Al_2O_3. Alumina occurs in nature as a mineral called *corundum.* Alumina and water occur in different combinations in the minerals boehmite, diaspore, and gibbsite. These minerals are found in *bauxite,* the chief source of the alumina from which aluminum is made. Refined alumina has wide use as an *abrasive,* a material used for grinding and polishing. Alumina resists high temperatures and is a poor conductor of electric current, so it is used in furnace linings and electrical insulators. A white clay called *kaolin,* which contains alumina, is used to make porcelain dinnerware.

Alumina occurs in several crystal forms. These forms have the same chemical formula but differ in the arrangement of their aluminum and oxygen atoms. The various forms can be changed from one to another by heating them to certain temperatures. David F. Hess

Aluminum alloys have a variety of uses because of their valuable properties. For example, the metals are lightweight but strong and so are used in the construction of airplanes. Aluminum cans chill quickly and can be recycled. Flexible aluminum foil is used in storing and cooking food.

Aluminum

Aluminum, *uh LOO muh nuhm,* is a lightweight, silver-colored metal that can be formed into almost any shape. It can be rolled into thick plates for armored tanks or into thin foil for chewing gum wrappers. It may be drawn into wire or made into cans. Aluminum does not rust, and it resists wear from weather and chemicals. Aluminum is called *aluminium* (*AL yuh MIHN ee uhm*) in English-speaking countries outside North America.

Pure aluminum is soft and has little strength. Thus, aluminum producers almost always *alloy* (mix) it with small amounts of copper, magnesium, zinc, and other elements to form *aluminum alloys.* The added elements give aluminum strength and other properties that make it one of the most useful metals. The world uses more aluminum than any other metal except iron and steel.

The largest share of aluminum alloy production goes to the packaging industry for use in such items as beverage cans, bottle caps, foil pouches, foil wrappers, and food containers. The construction industry uses aluminum alloys in such items as gutters, panels, residential siding, roofing, tubes for electric wires, and window frames. Manufacturers of transportation equipment use huge amounts of aluminum in airplanes, automobiles, boats, railroad cars, and trucks. Aluminum is used in much electrical equipment, including light bulbs, power lines, and telephone wires. Thousands of other products also contain aluminum. These products include air conditioners, cookware, golf clubs, knitting needles, lawn furniture, license plates, paints, refrigerators, rocket fuel, and zippers.

Aluminum is the most plentiful metallic element in the earth's crust and the third most common of all the elements, after oxygen and silicon. Aluminum makes up about 8 percent of the earth's crust. But unlike some other metals, such as gold and silver, aluminum never occurs *free* (uncombined) in nature. It is always chemically combined with other elements. People had no way of separating aluminum from these elements until the 1800's. Scientists then developed processes for separating the elements and producing aluminum. These processes have been used to make aluminum ever since.

Kenneth A. Bowman, the contributor of this article, is a technical specialist at Alcoa Laboratories.

Properties of aluminum alloys

Only a small percentage of aluminum is used in pure form. It is made into such items as electrical conductors, jewelry, and decorative trim for appliances and cars.

Properties of pure aluminum

Chemical symbol	Property	Value
Al	**Atomic number**	13
	Atomic weight	26.9815
	Density (at 20 °C)	2.70 (g/cm³)
	Melting point	660.2 °C
	Boiling point	2500 °C

Almost all aluminum is used commercially in alloy form with up to 15 percent of one or more other elements. The chief elements are copper, magnesium, manganese, silicon, tin, and zinc. Copper and magnesium increase the strength and hardness of aluminum. Magnesium also makes aluminum easier to weld. Manganese helps aluminum resist corrosion and also provides strength. Silicon lowers the melting point of aluminum and makes it easier to cast. Tin makes aluminum easier to shape with metalworking tools. Zinc, especially when combined with magnesium, gives added strength. Other elements may also be alloyed with aluminum for special purposes. These elements include bismuth, boron, cadmium, chromium, cobalt, iron, lead, lithium, nickel, sodium, titanium, vanadium, and zirconium.

Aluminum, with its alloys, has many valuable properties that make it an exceptionally useful metal. These properties include (1) light weight, (2) strength, (3) corrosion resistance, (4) electrical conduction, (5) heat conduction, and (6) light and heat reflection.

Light weight. Aluminum is one of the lightest metals. It weighs about 170 pounds per cubic foot (2,720 kilograms per cubic meter)—about a third as much as steel. As a result, aluminum has replaced steel for many uses. For example, some parts of airplanes, automobiles, and trucks are now made of aluminum rather than of steel because lighter vehicles use less fuel. Products packed in aluminum containers cost less to ship because the containers weigh less than those made of other metals. To make aluminum alloys even lighter, the lightest metal, lithium, is added to the aluminum.

Strength. Although pure aluminum is weak, certain aluminum alloys are as strong as steel. Such alloys are used in airplanes and trucks, in guardrails along highways, and in other products that require strength. Aluminum alloys lose some strength at high temperatures. But unlike many other metals, they get stronger at extremely low temperatures. Aluminum alloys are widely used in equipment for processing, transporting, and storing liquefied natural gas, which can have a temperature of −260 °F (−162 °C).

Corrosion resistance. Some metals *corrode* (wear away) if exposed to oxygen, water, or various chemicals. A chemical reaction occurs that causes the metals to rust or become discolored. When aluminum reacts with oxygen, however, the metal forms an invisible layer of a chemical compound called *aluminum oxide.* This layer protects aluminum from corrosion by oxygen, water, and many chemicals. It makes aluminum especially valuable for use outdoors, where the metal resists the effects of wind, rain, and pollution.

Electrical conduction. Aluminum and copper are the only common metals suitable for use as electrical conductors. Aluminum conducts electricity about 62 percent as well as copper. But aluminum weighs a third as much. Aluminum wire can therefore carry the same amount of electric power as copper wire that weighs twice as much. In addition, aluminum is more *ductile* than copper, which means it can more easily be drawn into wires. Aluminum wire is used for nearly all high-voltage power lines in the United States.

Heat conduction. The first large commercial use of aluminum was in cookware. Aluminum cookware heats up quickly and evenly. Aluminum also cools quickly, which helps make it popular for such items as beverage cans and ice cube trays.

Light and heat reflection. Aluminum reflects about 80 percent of the light that strikes it. This property has made the metal widely used in lighting fixtures. Aluminum also reflects heat well. Buildings with aluminum roofs reflect much of the sun's heat and so stay cooler in hot weather. When fire fighters must walk through flames, they wear special suits coated with aluminum.

Other properties. Aluminum is nonmagnetic, which makes it valuable for protecting electrical equipment from magnetic interference. Aluminum does not produce sparks when struck and can therefore be used near flammable or explosive materials. The metal is not poisonous, and so food can be safely wrapped in aluminum foil and cooked in aluminum pots. Aluminum can be shaped by almost any metalworking process. It can also be bolted, glued, riveted, soldered, welded, and otherwise joined by most methods used for other metals. Finally, aluminum can be recycled.

Sources of aluminum

Most minerals, rocks, and soils contain aluminum compounds. But aluminum can be made economically only from *bauxite.* Bauxite is the name for any ore that has a large amount of *aluminum hydroxide*—a chemical

Where bauxite is mined

This map shows the most important bauxite-mining areas of the world. The richest bauxite deposits lie in tropical and near-tropical regions.

combination of aluminum oxide and water. Aluminum oxide, also called *alumina,* is the compound from which aluminum is made.

Most bauxite consists of 30 to 60 percent alumina and 12 to 30 percent water. It also contains iron oxide, silica, and titanium oxide. The color of bauxite depends chiefly on how much iron oxide the ore contains. The more iron oxide it has, the darker the color. Bauxite may be white, cream, gray, pink, yellow, red, or brown. Most bauxite is as hard as rock, but some is as soft as clay.

The richest deposits of bauxite lie in tropical and near-tropical regions. Enough bauxite deposits have been found to last several hundred years. The leading bauxite-mining countries include Australia, Guinea, Jamaica, and Brazil.

Most bauxite deposits lie near the surface of the earth and are mined by the *open-pit method.* In this process, bulldozers and other earthmoving machines first clear away the *overburden*—the soil, rocks, and trees that cover the deposits. Next, explosives blast the ore loose. Huge power shovels scoop up the bauxite, and trucks or railroad cars carry it to a processing plant.

At the processing plant, the bauxite is crushed and then washed to remove clay and dirt. Some of the water in the bauxite is removed by drying the ore in *kilns* (ovens). The bauxite is then ground into a powder and shipped to a refining plant.

How aluminum is produced

There are two chief steps in producing aluminum. (1) refining the bauxite to obtain alumina and (2) smelting the alumina to obtain aluminum. After smelting, the molten aluminum is cast into blocks called *ingots* or other forms that will be shaped into finished products. It takes 4 to 6 pounds of bauxite to make 1 pound of aluminum.

Refining the bauxite separates the alumina in the ore from the iron oxide, silica, and titanium oxide. To separate the alumina, aluminum producers use the *Bayer process.* This technique was patented by Karl Joseph Bayer, an Austrian chemist, in 1888.

The first step of the Bayer process is mixing powdered bauxite with a solution of *caustic soda* (sodium hydroxide). Machines pump the mixture into large tanks called *digesters.* The digesters heat the mixture under pressure at 300 to 480 °F (150 to 250 °C) for about 30 minutes. The alumina dissolves in the caustic soda, forming a solution of *sodium aluminate.* The other materials in the bauxite remain as solids and are called *red mud* because of their color.

The mixture of sodium aluminate solution and red mud next passes through a series of tanks in which cloth filters separate the liquid from the solids. The red mud is discarded. The sodium aluminate solution is cooled slightly and sent to tanks called *precipitators.* Crystals of aluminum hydroxide are then added to the solution, which is *agitated* (stirred) for several days. This process causes most of the alumina in the solution to *precipitate* (come out of solution) and collect on the crystals.

After the precipitation is complete, the solution is filtered to separate the aluminum hydroxide crystals from the liquid. The crystals are washed to remove any impurities and then heated at 2000 to 2200 °F (1090 to 1200 °C). The heat drives out water, leaving a fine white powder of alumina. The alumina is composed of aluminum and oxygen. To recover the alumina that did not precipitate, manufacturers take the liquid and refine it with a new batch of bauxite and caustic soda. Small amounts of lime and soda ash may also be added.

Smelting the alumina separates the aluminum from the oxygen. The smelting is done by the *Hall-Héroult process.* This method was developed independently in 1886 by two scientists. They were Charles Martin Hall of the United States and Paul L. T. Héroult of France.

Aluminum producers begin the Hall-Héroult process by dissolving the alumina in a chemical bath composed mainly of *cryolite* (sodium aluminum fluoride). The bath also contains a little aluminum fluoride and calcium fluoride. The bath is held in large rectangular steel containers and heated to about 1740 °F (950 °C). The containers, called *pots* or *cells,* have a carbon lining.

In a process called *electrolytic reduction,* one or more carbon blocks suspended in each pot send an electric current through the bath. The current flows to the carbon lining, completing the electric circuit. The blocks act as the *anode,* or positive pole of the circuit, and the lining acts as the *cathode,* or negative pole. As the current flows through the bath, the alumina breaks apart. The oxygen in the alumina combines with the carbon in the anode and is released as carbon dioxide gas. The aluminum metal collects at the cathode at the bottom of the pot. See Electrolysis.

An aluminum plant may have as many as 200 pots electrically connected to one another in long rows called *potlines.* The reduction of alumina to aluminum goes on continuously. Alumina is added to the pots regularly, and the electric current keeps the bath at the proper temperature. A large pot may produce more than 2 tons (1.8 metric tons) of aluminum daily.

Casting the molten aluminum. About once a day, molten aluminum from the potlines is drawn off into pots called *crucibles.* Each crucible holds 4,000 to 8,000 pounds (1,800 to 3,600 kilograms) of aluminum. Most of

How aluminum is made

Aluminum comes from *bauxite,* an ore that has a large amount of a compound called *alumina.* Aluminum making involves separating the alumina and then obtaining aluminum from it.

WORLD BOOK diagram by Arthur Grebetz

Bauxite is crushed and then mixed with a solution of *caustic soda.* A tank called a *digester* heats the mixture under pressure. The heat and pressure cause the alumina in the bauxite to dissolve in the caustic soda, forming a solution of *sodium aluminate.* The other materials in the bauxite, which are called *red mud,* remain as solids and are filtered out.

Alumina comes out of the sodium aluminate solution in a tank called a *precipitator.* The solution is *agitated* (stirred) in the precipitator after crystals of aluminum hydroxide have been added. The stirring causes alumina in the solution to collect on the crystals. The solution is then filtered to separate the crystals, which are heated in a *kiln* (oven). The heat drives the water out of the aluminum hydroxide, leaving a fine white powder of alumina.

Aluminum is made in a carbon-lined pot. The alumina is first dissolved in a chemical bath in the pot. Carbon blocks suspended in the pot send an electric current through the bath. The current breaks the alumina apart, and molten aluminum collects at the bottom of the pot. The aluminum is siphoned into a pot called a *crucible* and later cast into forms called *ingots* and *billets.*

the aluminum is cast into ingots. There are two types of ingots: (1) fabricating ingots and (2) foundry ingots. Aluminum is also cast into forms called *billets.*

Fabricating ingots, or *rolling ingots,* are used by aluminum producers to make plates, sheets, and foil. The ingots may be 30 feet (9 meters) long, 6 feet (1.8 meters) wide, and 2 feet (0.6 meter) thick. They may weigh up to 18 short tons (16 metric tons). To make fabricating ingots, producers alloy other metals with the molten aluminum in a furnace and then purify the mixture. Scrap aluminum and recycled aluminum may also be added. The purification process, called *fluxing,* consists of pumping nitrogen, argon, or other gases through the liquid. The gas causes impurities to float to the surface, where they are skimmed off. During fluxing, chemical reactions cause some hydrogen gas to be trapped in the liquid. In a process called *degassing,* chlorine or some other gas is added to remove the hydrogen.

After fluxing and degassing, the molten aluminum alloy is filtered to remove solid impurities. Then it is cast into ingots, usually by the *direct chill method.* In this process, the alloy is poured into a mold, which is then passed through a spray of cold water. The water quickly cools and freezes the alloy.

Foundry ingots, also called *alloy ingots* or *remelt ingots,* weigh 4 to 50 pounds (1.8 to 23 kilograms). In most

cases, the molten aluminum is poured from the crucibles directly into molds, where it cools and hardens gradually. Aluminum producers sell foundry ingots to plants called *foundries.* The foundries remelt the ingots with scrap and recycled aluminum and perform the alloying, fluxing, and degassing operations themselves. The alloyed aluminum is then recast and turned into parts for appliances, automobiles, and other products. Aluminum producers supply some foundry ingots in alloy form. Foundries near aluminum plants may buy molten aluminum that comes directly from the potlines to eliminate the need for remelting.

Billets are made either in long rectangular shapes that look like railroad ties or in the shape of thin poles. They are produced in the same way as fabricating ingots. Billets can be made into *bars, rods,* and parts for thousands of items. Bars look like small rectangular billets. Bars may also be hexagonal or octagonal. Rods look like small pole-shaped billets. Bars and rods are made into tubing, wire, and various other products.

How aluminum is shaped and finished

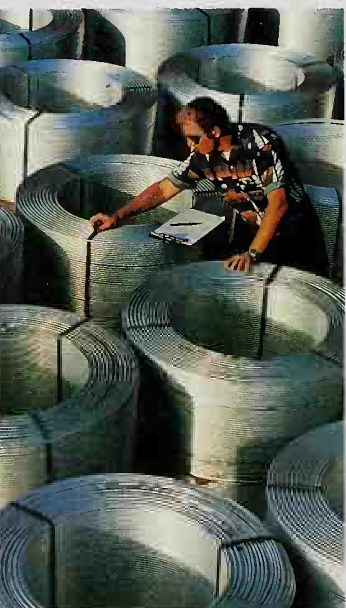
Aluminum ingots and billets can be shaped by any of the metalworking processes. These processes include (1) rolling, (2) casting, (3) extruding, (4) drawing, (5) forging, and (6) machining. After the aluminum is shaped, various finishes may be applied.

Rolling consists of reducing the thickness of fabricating ingots by squeezing them between pairs of heavy rollers. The ingots are heated and then rolled to a thickness of 1 to 3 inches (2.5 to 7.6 centimeters). After cooling, the metal is rolled again to form plates, sheets, or foil. Aluminum plates are $\frac{1}{4}$ inch (6.4 millimeters) thick or more. They are used in such things as railroad cars, ships, and storage tanks. Aluminum sheets measure $\frac{6}{1,000}$ to $\frac{1}{4}$ inch (0.15 to 6.4 millimeters) thick. They are used for the "skins" of airplanes and in such products as awnings and cooking utensils. Aluminum foil is less than $\frac{6}{1,000}$ inch (0.15 millimeter) thick. It has many household uses, especially in cooking and in wrapping food. Rolling may be used to shape aluminum billets into bars and rods.

Casting is a process in which alloyed foundry ingots are melted and then poured or forced into molds of a desired shape. The aluminum is removed from the molds after it hardens. Casting is used to make parts of particular items, such as the bottoms of electric irons or parts for automobile engines. See **Cast and casting.**

Extruding consists of forcing a heated billet through an opening in a tool called a *die.* A ram at one end of a cylinder forces the billet through a die opening at the other end. The aluminum comes out shaped like the die opening. The extrusion process is used to make rods and tubing, trim for automobiles, and frames for doors and windows. See **Extrusion.**

Drawing is used to produce aluminum wire and tubing. To make wire, a pointed aluminum rod is pulled through a series of successively smaller dies. The rod becomes wire when it reaches a diameter of less than $\frac{3}{8}$ inch (9.5 millimeters). Tubing is made by pulling an aluminum rod through one die. A steel bar called a *mandrel* extends through the center of the die and hollows out the rod.



Deep drawing forms aluminum into beverage cans, beer barrels, pots and pans, and various other containers. In this process, a ram forces aluminum plate or an aluminum sheet into a cavity of the desired shape.

Some shapes of aluminum

Reynolds Aluminum

Aluminum sheeting is made by squeezing ingots between pairs of heavy rollers. The sheeting shown above will be used for the *siding* (outside walls) of buildings.

Aluminum Company of America

Aluminum tubing is formed by forcing a billet or rod through an opening in a tool called a *die.* The tubing above will be used in air-conditioning units.

Aluminum Company of America

An aluminum forging is made by hammering an ingot or billet into the desired shape. This forging will be installed in the tail section of an airplane.

Forging is the process of hammering or pressing heated aluminum ingots or billets into the desired shape. Forging produces exceptionally strong parts for use in aircraft landing gear, truck wheels, tools, and various other items. See **Forging**.

Machining. Aluminum can be shaped with a variety of machine tools, including drills, grinders, saws, and shears. Such tools shape aluminum bars and rods into bolts, screws, and other small items. Machining may also be used to put final touches on products that have been cast or forged. See **Machine tool**.

Other shaping processes produce aluminum in such forms as powders and pastes. Powders and pastes consist of finely ground particles of aluminum. Aluminum powder goes into such products as explosives and inks. In paste form, aluminum is used in paints and in metallic finishes for automobiles.

Aluminum powder is also used to produce gears and other small parts by a process called *powder metallurgy*. In this process, the aluminum powder is pressed into the desired shape and then heated to bond the particles together. Powders of other metals also may be mixed with the aluminum. Powders of aluminum alloys also may be used. The item is further shaped by forging or some other process. See **Powder metallurgy**.

Finishing aluminum. Aluminum has an attractive natural appearance and so is often used without a special finish. However, various finishes may be used for decoration or to improve resistance to corrosion and wear. More kinds of finishes can be applied to aluminum than to any other metal. There are four types of finishes. They are (1) mechanical, (2) chemical, (3) electrochemical, and (4) applied.

Mechanical finishes include such processes as *embossing* and polishing. In embossing, a raised pattern is made on aluminum sheets by passing them between rollers that have been engraved with a design. A method called *barrel burnishing* polishes aluminum articles in a revolving or vibrating barrel that contains an *abrasive* (gritty) substance.

Chemical finishes include acid and alkaline *etches,* which eat designs into aluminum. Acid etches are also used to remove stains from the metal and to prepare it for further finishing. Alkaline etches may be used to give aluminum a dull finish.

Electrochemical finishes include *anodizing* and *electroplating.* Anodizing thickens aluminum's natural coating of aluminum oxide and thus increases resistance to corrosion, scratching, and wear. It also makes aluminum easy to dye. Electroplating involves coating aluminum with another metal. Certain coatings improve aluminum's corrosion resistance, electricity conduction, or other properties. See **Anodizing; Electroplating**.

Applied finishes include such coatings as enamel, lacquer, paint, and plastic film. They may be applied by dipping, spraying, or other methods.

The aluminum industry

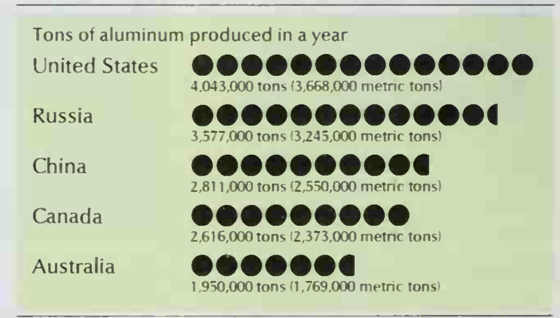
About 50 countries produce aluminum. The world's annual aluminum production totals about 27 million tons (24 million metric tons). The United States is the leading aluminum producer, accounting for about 15 percent of the world total.

The *primary aluminum industry* consists of companies that produce aluminum ingots and billets and shape them into such forms as plates, sheets, foil, bars, rods, and wires. The firms also sell the ingots and billets to foundries in the *secondary aluminum industry,* which specializes in shaping aluminum. Specialized workers in the primary aluminum industry include engineers, geologists, and metallurgists.

In the United States, the primary aluminum industry produces about 4 million tons (3.6 million metric tons) of the metal yearly. The leading aluminum companies in the country are Alcoa Inc., Alumax Incorporated, Reynolds Metals Company, and Kaiser Aluminum and Chemical Corporation. Two labor unions—the Aluminum, Brick and Glass Workers International Union (ABGWIU) and the United Steelworkers of America (USWA)—represent most of the workers in the aluminum industry.

Aluminum producers in the United States use about 11 million tons (10 million metric tons) of bauxite annually. They import all of this bauxite, chiefly from Brazil, Guinea, Guyana, and Jamaica. Aluminum producers also import alumina.

In Canada, the primary aluminum industry produces about 2 $\frac{1}{2}$ million tons (2.3 million metric tons) of the metal yearly. About 90 percent of Canada's aluminum is made in Quebec. The country's leading aluminum manufacturer is Alcan Aluminum Limited. Canada produces no bauxite. It imports most of this ore from Guinea, Guyana, and Suriname.



In other countries. Only about a third of the aluminum-producing countries perform each step in aluminum production—mining the bauxite, refining the ore, and smelting the alumina. In some countries, such as Guinea and Jamaica, the industry mines and refines bauxite for export but produces no aluminum. Other countries, including Germany and Japan, import bauxite and then refine it and smelt the alumina. Some countries, such as Norway and Tajikistan, import alumina but not bauxite.

Countries that perform each step in the production process include Australia, Brazil, China, Russia, and Suriname. Several bauxite-mining countries have joined together to form the International Bauxite Association (IBA).

Recycling

Recycling has become a very important aspect of the aluminum industry in many countries. In the United

Leading aluminum-producing countries

States, scrap makes up about 30 percent of the total aluminum supply. Heavily recycled items include used beverage cans, parts from old automobiles, and scrap accumulated during the manufacture of aluminum products. Beverage cans represent the leading product made from aluminum by volume. More than half the beverage cans used in the United States are recycled.

One benefit of recycling aluminum is that it conserves natural resources. The most important natural resource saved is energy. Recycling saves about 95 percent of the energy required to make aluminum from bauxite. One recycled aluminum can saves enough energy to keep a 100-watt light bulb burning for about 3 $\frac{1}{2}$ hours. In addition, recycling preserves natural beauty. It also reduces the amount of garbage sent to sanitary landfills.

History

The word *aluminum* comes from the term *alumen*. Alumen is the Latin name for *alum*, a group of aluminum compounds that occur in nature and which ancient peoples used in dyeing textiles. In 1746, Johann Heinrich Pott, a Prussian chemist, prepared alumina from alum. Scientists believed that alumina was a chemical compound that consisted of oxygen and an unknown metal. The British chemist Sir Humphry Davy called this metal *alumium* and later changed the name to aluminum. In 1809, Davy formed an alloy of iron and aluminum by electrically melting alumina with iron and carbon.

The first aluminum. In 1825, Hans Christian Oersted, a Danish scientist, produced the first aluminum. Oersted prepared aluminum chloride from alumina. He then heated the aluminum chloride with an alloy of potassium and mercury, and a small lump of impure aluminum formed in the alloy.

In 1827, Friedrich Wöhler, a German chemist, produced aluminum as gray powder by heating aluminum chloride with potassium. In 1845, Wöhler produced aluminum particles large enough to be weighed. He discovered that aluminum was lightweight. Wöhler was the first scientist to describe several other properties of aluminum.

In 1854, Henri Étienne Sainte-Claire Deville, a French chemist, improved on Wöhler's method. Deville used sodium instead of potassium to break down aluminum chloride. This process produced larger quantities of aluminum. Commercial aluminum plants using Deville's method soon opened in France. The price of aluminum dropped from $115 a pound ($254 a kilogram) in 1855 to $17 a pound ($37 a kilogram) in 1859. However, it was still too costly for widespread use.

The growth of the aluminum industry increased greatly following two important developments in the 1880's. They were the invention of the Hall-Héroult process and of the Bayer process.

In 1886, two scientists—Charles Martin Hall of the United States and Paul L. T. Héroult of France—developed an inexpensive way to make aluminum. Neither scientist knew that the other was working on the problem. However, each thought of dissolving alumina in the mineral cryolite and separating aluminum from the mixture by electrolytic reduction. Today, the Hall-Héroult process is used to produce nearly all the aluminum in the world.

Karl Joseph Bayer, an Austrian chemist, further reduced the cost of aluminum production. In 1888, he patented an inexpensive method for obtaining alumina from bauxite. The aluminum industry still uses the Bayer process to produce alumina. The Hall-Héroult and Bayer processes are described in the section *How aluminum is produced*.

Hall and several business associates organized the Pittsburgh Reduction Company in 1888. The company began producing 50 pounds (23 kilograms) of aluminum a day. The firm changed its name to the Aluminum Company of America (Alcoa) in 1907. By 1909, Alcoa was producing 16,500 tons (14,970 metric tons) a year. The price of aluminum dropped to less than 30 cents a pound (66 cents a kilogram). Héroult formed a Swiss aluminum company in 1888, but it did not begin production immediately. In 1902, the Northern Aluminium Company, Limited (now Alcan Aluminium Limited), was founded in Canada.

Aluminum production soared during World War I (1914-1918) as the fighting nations increased output to help fill their military needs. During the 1920's, the development of new aluminum alloys and of improved methods of turning aluminum into useful products continued to boost production. The Great Depression of the 1930's cut world aluminum output almost in half. But the start of World War II (1939-1945) brought tremendous expansion in production. In 1941, Reynolds Metals Company became the second producer of primary aluminum in the United States.

After World War II, the aluminum industry developed many products that have become commonplace. The first successful aluminum foil wrap appeared in 1947. Also in the 1940's, aluminum began to replace brass in the base of light bulbs. High-strength aluminum wire for power lines was introduced in 1957. Aluminum cans became popular in the 1960's. Today, nearly all beverage cans are made completely of aluminum.

Recent developments. The demand for aluminum has grown steadily with the continuing development of new uses for the metal. For example, the auto industry has used increasing amounts of aluminum in cars to lessen their weight and so improve fuel efficiency.

During the late 1900's, several aluminum producers began to sell aluminum to any customer who would buy it. This practice led to aluminum's becoming an international *commodity* (product of trade). In 1978, aluminum

appeared on the London Metal Exchange (LME). In 1983, it was listed on the Commodities Exchange (COMEX) in the United States. Only a small amount of aluminum is sold through these markets. But the published market prices are used to set the price of aluminum when it is sold by a producer to a customer who will fabricate the metal into products.

The collapse of the Soviet Union in 1991 led to a sharp drop in the world price of aluminum. The Soviet Union had developed an enormous defense industry that required massive amounts of aluminum. After the collapse, the newly independent former Soviet republics maintained their own defense industries. However, the total size of these industries was much smaller than the Soviet industry had been. As a result, the demand for aluminum in the former Soviet Union was much decreased.

The republics also needed money badly. To raise money, they began to export aluminum to countries outside the former Soviet Union. Because of the resulting oversupply, the price of aluminum plunged. The aluminum industry throughout the world responded by closing relatively old and inefficient smelters.

Questions

What is the *Hall-Héroult process?* What is the *Bayer process?*
Why is aluminum wire used for nearly all high-voltage power lines in the United States?
Which are the four largest aluminum companies in the United States? How much of the nation's aluminum do they produce?
What percentage of bauxite used by American aluminum producers is imported?
What are some benefits of recycling aluminum?
Why is aluminum usually alloyed with other elements?
How are aluminum plates, sheets, and foil made?
How much bauxite does it take to produce 1 pound (0.5 kilogram) of aluminum?
What is the purpose of *anodizing* aluminum?
How does aluminum resist corrosion?

Alvarado, *AHL vah RAH thoh,* **Pedro de** (1485?-1541), helped Hernando Cortés subdue the Aztec in Mexico and conquered Guatemala himself. Born in Badajoz, Spain, Alvarado went to the West Indies in 1510. In 1518, he joined an expedition led by Juan de Grijalva to southern Mexico. Alvarado accompanied Cortés to Mexico in 1519. After Cortés conquered Mexico in 1521, he sent Alvarado to seize Guatemala. Alvarado succeeded in 1524 with the help of Indian allies. In 1525, he conquered El Salvador for Spain and directed the founding of the capital city, San Salvador. Alvarado became governor of Guatemala. Helen Delpar

Alzheimer's disease, *AWLTS hy muhrz,* often abbreviated as *AD,* is a brain disease that causes increasing loss of memory and other mental abilities. Alzheimer's disease is the most common cause of severe memory loss in elderly adults. The disease attacks few people before age 60, but it becomes increasingly common with age. In the past, elderly adults suffering from severe memory loss were often labeled senile, but they were probably suffering from what doctors now recognize as AD. The disease is named after Alois Alzheimer, a German psychiatrist and neuropathologist, who first described the effect of the disease on brain cells in 1907.

Diagnosis. There is no single test used to identify people with AD. Patients, or their family members, may first notice increasing forgetfulness, often accompanied by reduced interest or awareness of ongoing activities. Patients may ask the same question repeatedly, misplace objects, forget appointments, and neglect their appearance. Physicians use imaging techniques, such as computed tomography (CT) or magnetic resonance imaging (MRI), to determine that other brain disorders, such as stroke or a brain tumor, are not causing the symptoms. Doctors suspect AD if no other disease or disorder is found to cause the symptoms.

As the disease progresses, memory loss increases, and patients begin to lose other mental functions. They may not understand what others are saying, or lose the ability to name familiar people or objects. Patients can

become confused or disoriented, easily getting lost even in familiar locations. In later phases, patients lose the ability to remember or talk meaningfully. Eventually, they cannot care for themselves, and most become bedridden and require constant care. In their weakened condition, patients are vulnerable to pneumonia and other infectious diseases. Most patients die from such infections 10 to 12 years after developing AD.

Only an autopsy performed after the patient dies can confirm the diagnosis of AD. Examination of the brain tissue with a microscope reveals many deposits of a protein called *amyloid.* These abnormal deposits, called *plaques,* are surrounded by damaged and dead nerve cells. Tangled clumps of abnormal *filaments* (threadlike structures) fill many of the nerve cells in the brain of patients who died of AD. Gaping holes in the brain tissue, caused by the destruction of nerve cells, appear in severe cases. Chemical tests conducted after an autopsy show that AD patients have lower levels of *acetylcholine,* a brain chemical that transmits nerve impulses.

In a small number of cases, AD is caused by *mutations* (random changes) of genes on chromosome pairs known as chromosomes 1, 14, and 21. Another gene, located on chromosome 19, is strongly associated with the development of AD. The gene controls production of one of three forms of a protein called *apolipoprotein E* (ApoE). A person inherits two genes for ApoE production, one from each parent. Each gene produces one of three types of ApoE, known as ApoE-2, ApoE-3, and ApoE-4. Persons possessing one or two ApoE-4 genes have a higher risk of developing AD after the age of 60 than people who do not have the ApoE-4 gene. However, scientists do not think the ApoE-4 gene causes AD. Some people with two ApoE-4 genes do not develop AD, while others who do not have the gene at all go on to develop AD. Scientists do not know why different ApoE types are related to increased risk for the disease.

Treatment. There is no cure for AD. Good nutrition, hygiene, and reassurance can help preserve the comfort and dignity of AD patients. Such drugs as *donepezil* and *revistigmin* help improve mental function and slow the progression of the disease. These drugs help compensate for the lower levels of acetylcholine in the brain of AD patients by removing other chemicals that destroy acetylcholine. Physicians may administer high doses of vitamin E, which helps protect nerve cells from damage by the amyloid plaques accumulating in the brain. Scientists are investigating estrogen replacement therapy for women, anti-inflammatory drugs, and a vaccine against amyloid plaques as possible treatments to prevent or slow the development of AD.

Families provide most of the care that AD patients receive and should be included in decisions about care. Family members can become distressed by the demands of providing care to relatives whose disease can last more than 10 years. The Alzheimer's Association offers support and information to patients and their families. Jeffrey L. Cummings

A.M. stands for the Latin words *ante meridiem,* which mean *before noon.* See Hour.

AMA. See American Medical Association.

Amadís of Gaul, *AM uh dihs,* is a famous Spanish romance of chivalry. It may have appeared in Spain in the 1300's, but the first preserved version, *The Four Books of the Virtuous Knight Amadís of Gaul,* was published in 1508. At least part of the work is attributed to Garci Ordóñez (or Rodríguez) de Montalvo.

The story describes the adventures of a romantic, brave, modest hero named Amadís. His aristocratic manners and strict sense of justice reveal a Renaissance interpretation of the ideal medieval knight. The story is marked by flowery prose. The episodes deal with spectacular and fantastic events, including knightly duels, magic spells, and fierce combat with giants and dragons. Young Amadís loves Princess Oriana and, despite many obstacles and temptations, remains faithful to her until their marriage. Cervantes was influenced by *Amadís* in creating Don Quixote. Harry Sieber

Amado, *ah MAH doh,* **Jorge,** *ZHAWR zhay* (1912-2001), was a Brazilian novelist. Amado was born on Aug. 10, 1912, in Ilhéus in the state of Bahia, along the northeastern coast of Brazil. He wrote mainly about the people of Brazil's lower classes living in his native region, especially the area around the port of Salvador. In a style that is both poetic and realistic, he used the language of these people to portray their infectious zest for life.

Before 1958, Amado wrote essentially Marxist novels, such as *Jubiaba* (1935) and *The Violent Land* (1942), which reflected his sympathy for victims of social injustice. Between 1937 and 1952, he was exiled several times because of his political views. Beginning with *Gabriela, Clove and Cinnamon* (1958), he wrote in a more sophisticated style that emphasized satirical humor. Many critics regard *The Two Deaths of Quincas Wateryell* (1961) as his masterpiece.

Amado made an important contribution to Brazilian literature by becoming the first major writer to praise his nation's extensive African heritage. This theme dominates one of his finest works, *Tent of Miracles* (1969). Among his other novels are *Dona Flor and Her Two Husbands* (1966), *Tieta* (1977), *Pen, Sword, Camisole* (1979), *Showdown* (1984), and *The War of the Saints* (1993). Earl E. Fitz

Amalekites, *uh MAL uh kyts,* were a desert people who lived south of Canaan (later called Palestine) in Old Testament times. The Israelites considered them their oldest enemies. Joshua defeated the Amalekites in the late 1200's B.C. King Saul defeated them 200 years later. Afterward, the Amalekites destroyed Ziklag, the town where David and his followers lived. David found them celebrating this victory. He killed many, but 400 escaped. H. Darrell Lance

Amalgamated Clothing and Textile Workers Union. See Union of Needletrades, Industrial and Textile Employees.

Amanites, *uh MAN nyts,* are members of a religious group called the Amana Church Society. The word *Amana* comes from the Song of Solomon 4:8. It is the name of a mountain, and means *true* or *fixed.*

The society was founded by Eberhard Gruber and Johann Rock in Germany in 1714. It was originally called the Community of True Inspiration. Members led simple lives according to the Word of God, revealed not only in the Bible but also in the "true inspiration" of their prophets. The last leader believed to be inspired died in 1883. But the group continued to read and study the testimonies of their past prophets.

Christian Metz and Barbara Heinemann led the group to the United States in 1842. It settled near Buffalo, New York, and was called the Ebenezer Society. Members owned villages and lands in common. They moved near Cedar Rapids, Iowa, in 1855. They founded seven villages: Amana, East Amana, High Amana, Homestead, Middle Amana, South Amana, and West Amana. The Amanites farmed and made woolen goods and drugs.

The society gave up its communal economic life in 1932, during the Great Depression. But the villagers continued to live a simple life and today make crafts and operate restaurants serving traditional foods. The society became a cooperative stock company known for manufacturing refrigerators and other household appliances. The religious members organized the Amana Church Society. Charles H. Lippy

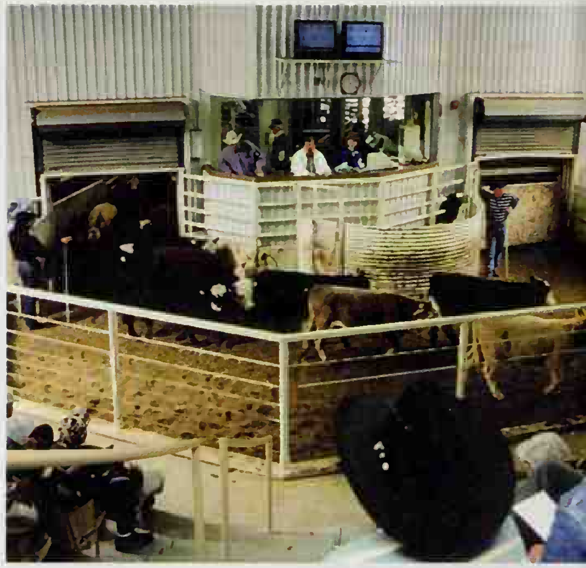
Amaranth, *AM uh ranth,* is the common name of a *genus* (group) of plants that includes weeds, garden flowers, and crops. This genus is made up chiefly of herbs. Amaranths grow widely, especially in warm climates. The name *amaranth* comes from a Greek word meaning *unfading.* It was given to amaranths because their flowers retain their color even when dried.

Among the weeds that belong to the amaranth genus are *giant pigweed* (often called *redroot), spreading pigweed,* and a kind of tumbleweed. *Love-lies-bleeding* is an ornamental amaranth with long, drooping, crimson flower clusters. The *purple amaranth* is a tall plant with late-blooming, pinkish-purple flower clusters. Amaranths cultivated for their edible seeds are called *grain amaranths.* Amaranth seeds were an important food for the Aztec and Inca Indians. Anton A. Reznicek

Scientific classification. Amaranths are in the amaranth family, Amaranthaceae. The scientific name for the love-lies-bleeding is *Amaranthus caudatus.* Purple amaranth is *A. cruentus.*



See also **Pigweed; Tumbleweed.**

WORLD BOOK illustration by Christabel King

An ornamental amaranth called *love-lies-bleeding* has a number of long, drooping clusters of crimson flowers.

Amarillo, *AM uh RIHL oh* (pop. 173,627; met. area pop. 217,858), is the largest city and commercial center of the Panhandle of northern Texas. It serves as a major distribution and processing center for cattle, oil, and other products. For its location, see **Texas** (political map).

Amarillo Convention & Visitors Council

A cattle auction in Amarillo offers animals from the area to the highest bidder. Amarillo is a major distribution and processing center for cattle, oil, and other products.

Cattle auctions held by the privately owned Amarillo Livestock Auction Company rank among the largest in the world. A large plant that slaughters cattle for beef operates outside Amarillo. Large deposits of oil and natural gas lie in the Panhandle, and Amarillo has many petrochemical plants. The city lies in the world's chief helium-producing area. An assembly plant for United States nuclear weapons is northeast of the city. Other industries include copper refining and the manufacture of fiberglass machine parts and cement products.

Amarillo's cultural attractions include an art center, a community theater, and a symphony orchestra. Downtown Amarillo has a Civic Center with convention and entertainment facilities. Amarillo has a community college and a branch of the Texas Tech medical school. West Texas A&M University and a branch of Texas State Technical College are near the city. The American Quarter Horse Association, the world's largest horse registry, has headquarters in Amarillo. Palo Duro Canyon, a major tourist attraction, is located just southeast of the city.

In 1887, construction crews of the Fort Worth and Denver City Railroad founded the settlement of Ragtown near what is now Amarillo. In the same year, a land developer laid out the site of Amarillo near the settlement. Settlers called the town *Amarillo,* which means *yellow* in Spanish. The name may refer to the yellowish soil that borders nearby Amarillo Creek.

Amarillo grew rapidly during the early 1900's, when other railroads began to serve the community and oil and natural gas were discovered in the area. The city has a council-manager form of government and is the county seat of Potter County. Dennis Spies

Amaryllis, *AM uh RIHL ihs,* is a family of more than 1,200 species of flowers. Most species grow outdoors in warm regions. In colder climates, amaryllises are usually grown indoors as potted plants in winter and transplanted outdoors in summer.

WORLD BOOK illustration by Richard Lewington, The Garden Studio

An amaryllis has a long stem and trumpet-shaped flowers. The belladonna lily, *pictured here,* is a popular species.

The plants in the amaryllis family have long stems and many long, narrow leaves. The flowers are made up of six petals, and they may grow in clusters or as a single blossom. Some of the amaryllises are especially fragrant. More than half of the amaryllis family are grown from bulbs. The remaining plants are grown from corms or rhizomes (see Corm; Rhizome).

Certain members of the amaryllis family look like plants in the lily family. The two families may be confused with each other.

The *belladonna lily* is a popular amaryllis that blooms from August to October. This lilylike plant grows from a bulb. Its stalk is 18 to 30 inches (46 to 76 centimeters) high. It is topped by a cluster of 6 to 10 flowers. The fragrant blossoms are usually 3 inches (8 centimeters) long and may vary in color from rose-red to white. The *narcissuses* and *snowdrops* are other popular members of the amaryllis family. August A. De Hertogh

Scientific classification. The amaryllis family is Amaryllidaceae. The scientific name for the belladonna lily is *Amaryllis belladonna.*

Amateur Athletic Union (AAU) is an organization that promotes and develops amateur sports and physical fitness programs in the United States. The AAU is a nonprofit, volunteer group. It consists of about 5,000 athletic clubs affiliated with 58 regional associations.

The largest program sponsored by the organization is the Junior Sports and Junior Olympic Games. This annual competition attracts about 2 million participants from 8 to 18 years old. Participants compete in about 20 sports, including basketball, gymnastics, volleyball, track and field, and wrestling. The AAU sponsors other athletic competitions at the local, state, regional, and national level. It also conducts adult sports programs and physical fitness programs for youth and adults. In addition, the AAU annually presents the James E. Sullivan Award to the nation's outstanding amateur athlete. The award is named for an early AAU executive.

The AAU was founded in 1888. It has headquarters in Indianapolis.

Critically reviewed by the Amateur Athletic Union of the United States

Amateur radio. See Radio, Amateur.

Amati family, *ah MAH tee,* was a family of violin makers who worked in Cremona, Italy, from the 1500's to the 1700's. Amati violins come in a variety of varnish tones ranging from dark red to light yellow. The violins have refined proportions and curves, and a high-arched shaping of the top. The arch helps produce a sweet, somewhat restrained soprano sound that was preferred for the intimate ensemble music popular in the 1600's.

Andrea Amati (about 1511-1579) was one of the first violin makers to give the instrument its distinctive shape and features. His work was carried on by his sons, Antonio (born about 1540) and Girolamo (1561-1630). Girolamo's son, Nicolo (1596-1684), was the most famous and influential Amati. Nicolo trained many instrument makers, including Andrea Guarneri and Antonio Stradivari. Nicolo's son, Girolamo II (1649-1740), was the last violin maker in the family. Abram Loft

Amazon. See Amazons.

Amazon rain forest is the world's largest tropical rain forest. It covers approximately 2 million square miles (5.2 million square kilometers) in the Amazon River Basin of South America. About two-thirds of the rain forest lies in Brazil. The forest also occupies parts of Bolivia, Peru, Ecuador, Colombia, and Venezuela. The Amazon rain forest receives an average annual rainfall of 50 to 175 inches (130 to 445 centimeters). Temperatures average about 80 °F (27 °C).

Trees in most of the Amazon rain forest grow in several distinct layers. Some trees, called *emergents,* tower above the rest of the forest and may reach heights of over 165 feet (50 meters). The *upper canopy* generally grows 65 to 165 feet (20 to 50 meters) high. Plants called *epiphytes,* or *air plants,* thrive in this layer. They include aroids, bromeliads, ferns, liverworts, mosses, and orchids. One or two *lower canopies* consist of saplings of the trees found in the upper canopy, in addition to smaller trees and shrubs. *Lianas* (woody vines) wind around tree trunks and branches, extending from the ground to the upper canopy. The canopies get sunlight, but they prevent much light from reaching the forest

WORLD BOOK map

Amazon rain forest covers much of northern South America. About two-thirds of the rain forest lies in Brazil. The rain forest also occupies parts of several other lands.

The Amazon rain forest abounds with lush plant life. Many kinds of animals also live there. The forest lies in the Amazon River Basin of South America. It is the world's largest tropical rain forest.

© Luiz C. Marigo from Peter Arnold

floor. Most of the Amazon rain forest has infertile soil.

The Amazon rain forest contains a wider variety of plant and animal life than any other place in the world. Tens of thousands of different plant species live there. A $2\frac{1}{2}$-acre (1-hectare) area of the rain forest may contain up to 280 or more species of trees. Many economically important plants live in the rain forest. They yield such products as Brazil nuts, cocoa, *curare* (an important drug), pineapples, and rubber. More than 1,500 species of birds make their homes in the rain forest. The region's rivers contain up to 3,000 species of fish. In addition, scientists believe that as many as 30 million different insect species may live in the forest.

The world's rapid population growth and increasing demands for natural resources have seriously threatened the Amazon rain forest. Loggers cut down trees, which the lumber industry uses to make wood products. Ranchers and farmers clear land to use for grazing beef cattle and growing crops.

© Michael Nichols, Magnum

Destruction of the Amazon rain forest threatens its plant and animal populations as well as its native peoples. The area pictured here was burned to clear land for cattle grazing.

Areas of the rain forest that have been cleared can regenerate. However, regenerated areas are much less diverse than the original forest. About 10 percent of the Amazon rain forest has been destroyed. Development, *deforestation* (the destruction of forests), and gold mining also threaten the culture of the few remaining native peoples of the Amazon rain forest. Many of these people depend on the forest to support themselves.

Wm. Wayt Thomas

See also **Forest** (Deforestation); **Rain forest; Yanomami Indians.**

Amazon River, *AM uh zahn,* is the world's second longest river and the chief river of South America. Only the Nile River in Africa is longer. The Amazon is 4,000 miles (6,437 kilometers) long—longer than the highway route between New York City and San Francisco. The Amazon carries more water than any other river—more than the Mississippi, Nile, and Yangtze rivers together.

The Amazon is too wide at many points for a person on one bank to see the opposite shore. The river ranges from $1\frac{1}{2}$ to 6 miles (2.4 to 10 kilometers) wide during most of its course. It widens to about 90 miles (140 kilometers) at its mouth. The depth of the Amazon averages about 40 feet (12 meters) and increases to more than 300 feet (90 meters) at some places.

The Amazon River Basin covers about 2,700,000 square miles (7,000,000 square kilometers) and includes the world's largest tropical rain forest. The temperature averages about 80° F (27° C) and varies little throughout the year. Rainfall in the Amazon region ranges from 50 inches (130 centimeters) in the low-lying areas to 120 inches (300 centimeters) near the Andes Mountains in Peru. The air is very humid in most of the river basin.

Most ships enter the Amazon River by way of the Pará River, on the southern side of Marajó Island. Ocean vessels can sail about 2,300 miles (3,700 kilometers) up the Amazon to Iquitos, Peru. Belém, on the Pará River about 90 miles (140 kilometers) from the Atlantic coast, and Manaus, 1,000 miles (1,600 kilometers) upstream from the mouth of the Amazon, are important ports. Ships bring in clothing, food, tools, and other products. They pick up such raw materials as animal skins, Brazil nuts,

Amazon River

Amazon River drainage basin

Swamp

WORLD BOOK map

lumber, and rubber. The ships also take aboard live birds, fish, and other animals bought by pet shops and zoos.

The course of the Amazon begins high in the Andes Mountains of Peru as a small stream called the Apurímac River. The Apurímac is located 17,200 feet (5,240 meters) above sea level. It flows northwest into the Ucayali River, the lower branch of the Amazon in Peru. The Ucayali flows north through the Andes and then turns east and joins the Marañón River, the upper branch of the Amazon. This junction takes place near Iquitos, Peru, and forms the main channel of the Amazon. The river continues eastward across Brazil and flows into the Atlantic Ocean on the northern side of Marajó Island.

The Amazon tumbles rapidly through the Andes and falls about 16,400 feet (4,999 meters) during the first 600 miles (970 kilometers). It falls about 800 feet (240 meters) more during the rest of its course. The river flows at about $1\frac{1}{2}$ miles (2.4 kilometers) per hour during the dry season. Its flow increases to about 3 miles (5 kilometers) per hour when the river is swollen by rain.

More than 200 smaller rivers flow into the Amazon. They include the Japurá, the Juruá, the Madeira, the Purús, the Tapajós, the Xingu, and the Rio Negro.

An unusually high ocean tide occasionally overpowers the current at the mouth of the Amazon. This creates a wall of water called a *bore* that measures up to 15 feet (4.6 meters) high and rushes upstream.

Animal and plant life. Many kinds of fish live in the Amazon River. They include the fierce, flesh-eating piranha and the pirarucú, one of the largest freshwater fish of South America. The basin area is the home of such animals as alligators, anacondas, monkeys, parrots, sloths, and many species of insects.

The Amazon rain forest has a great variety of plant

Loren McIntyre, Woodfin Camp Inc.

The muddy brown Amazon joins the blue-black waters of the Rio Negro in northwestern Brazil. The Rio Negro is one of the Amazon's chief tributaries.

life. Scientists have found more than 3,000 species of plants in 1 square mile (2.6 square kilometers) there. The trees stand as tall as 130 feet (40 meters). Their tops grow so close together that only a little sunlight can reach the ground.

History. Indians lived in the Amazon River basin before white people first came to the area. Vicente Yañez Pinzón, a Spanish explorer, was probably the first European to see the Amazon. In 1500, he sailed to the coast of what is now Brazil. During 1541 and 1542, another Spaniard, Francisco de Orellana, led the first exploration of the river by a European. His expedition followed the Amazon from the mouth of the Napo River in Peru to the Atlantic. During Orellana's journey, his group was attacked by what appeared to be female Indian warriors. The Spaniards called their attackers Amazons, after the female warriors in Greek mythology (see **Amazons**). The name was later given to the river and the nearby area.

In the mid-1800's, trees in the Amazon basin became an important source of rubber. But after about 1910, plantations in Southeast Asia began to make rubber more cheaply. The demand for Amazon rubber fell, and the economy of the region collapsed. Since the 1960's, the Brazilian government has built highways and airports in the Amazon basin. New towns and farms have been established in this region, and its population has grown.

Increasing demands for natural resources are threatening the Amazon rain forest. Mining and the clearing of land for agriculture and industry are adding to the rapid destruction of the plant and animal life in this environment. Jerry R. Williams

McIntyre, Loren. *Amazonia.* Sierra Club, 1991.

Amazons, *AM uh zahnz,* were a tribe of warrior women in Greek mythology. To the male-centered Greeks of the 400's B.C., the Amazons symbolized all that was barbaric and non-Greek. The Greeks believed that the Amazons inhabited a remote region of Asia Minor and maintained their female culture by mating periodically with men of neighboring tribes. The women sent their sons back to the tribes of their fathers, or enslaved them, rearing only the girls.

The name *Amazon* is usually taken to mean *breastless.* The women, according to some sources, seared off the right breast of each daughter so she could shoot the bow and arrow more easily.

Many references to Amazons appear in ancient Greek literature. For example, the Amazon queen Penthesileia aided the Trojans against the Greeks in the Trojan War. After killing many Greeks, she was killed by the Greek warrior Achilles.

Some scholars believe that the concept of a race of women warriors originated when the Greeks fought the Scythians, a people who lived north of the Black Sea. Scythian women sometimes fought alongside the men and had masculine habits. The Greek historian Herodotus believed the Sarmatians, who replaced the Scythians, were the product of a planned union of the Amazons and the Scythians. Nancy Felson

Ambassador is the personal representative of a country's head of state at the capital of another country. An ambassador is the nation's highest-ranking diplomat in the other country. The person's full title is *ambassador extraordinary and plenipotentiary.*

In the United States, the president appoints all ambassadors, with the approval of the Senate. The rank of ambassador is also given to American chiefs of mission to international organizations if the person is appointed by the president and confirmed by the Senate. For example, an ambassador heads the United States delegation to the United Nations.

An ambassador heads a country's embassy in the foreign capital. The staff may number several hundred people, including minister-counselors, counselors, diplomatic secretaries, consular officers, attachés, and clerks. The ambassador carries on negotiations with the foreign government that deal with the political, economic, and cultural relations between the two nations. The ambassador provides the official channel of communications by maintaining contacts with the head of state, the foreign minister, and other officials.

The ancient Greeks were among the first people to exchange diplomatic representatives. The Congress of Vienna in 1814 and 1815 and the Congress of Aix-la-Chapelle in 1818 placed diplomacy on a systematic basis by creating four classes of representatives. These classes consisted of ambassadors (the highest rank), ministers, ministers resident, and chargés d'affaires. During its early history, the United States appointed representatives of the three lower ranks. In 1893, the United States appointed its first ambassadors—to Britain, France, Germany, and Italy. Today, the United States assigns ambassadors to all countries with which it has diplomatic relations. Michael P. Sullivan

Amber is a hard, yellowish-brown fossilized resin. It comes chiefly from the resins of pine trees that grew in northern Europe millions of years ago. These resins were gummy materials mixed with oils in the trees. When the oils became *oxidized* (combined with oxygen), hard resins were left. These pine trees were buried underground or underwater, and the resins slowly changed into irregularly shaped lumps of amber. Lumps of amber often contain insects trapped as the resins flowed from the trees. Some lumps have air bubbles.

The largest supply of amber lies in the Baltic Sea area. It comes from a species of pine tree that is now extinct. Some experts consider this amber the only true amber. Central America has important deposits of amber from other sources. Most amber is mined from a claylike soil called *blue earth.* Amber is used to make beads, mouthpieces for pipes, and other ornaments.

The ancient Greeks called amber *elektron.* When they rubbed amber with cloth, it became electrically charged and attracted bits of lightweight material, such as straw and feathers. The word *electricity* comes from the Greek word *elektron.* Roger D. Barry

Ambergris, *AM buhr grees* or *AM buhr grihs,* is a waxy substance found in the intestines of some sperm whales. It has a musky smell when dried and was once used in expensive perfumes. Ambergris was added to perfume because its odor made the odor of the perfume last longer. Today, artificial substitutes have almost entirely replaced natural ambergris in perfume making.

Ambergris was once collected chiefly from the bodies of dead sperm whales. The whales also pass ambergris as a waste product, and clumps of it can sometimes be found in the water or on shore. John K. B. Ford

See also Whale (American whaling).

Amberjack is a large, fast-swimming game fish found in warm and tropical oceans. People who fish for sport prize the amberjack for its fierce fighting ability when hooked. Amberjacks have a streamlined body and a

yellowtail has a bright yellow tail and a yellowish stripe along the side of the body. It lives in coastal areas of the Pacific Ocean. Robert R. Rofen

Scientific classification. Amberjacks belong to the family Carangidae. The greater amberjack is *Seriola dumerili.* The yellowtail is *S. lalandei.*

Ambler, Eric (1909-1998), an English author, won fame for his well-constructed novels of intrigue and international adventure. He also wrote screenplays for motion pictures. Ambler's novels include *A Coffin for Dimitrios* (1939), *Journey into Fear* (1940), *The Light of Day* (1963), *The Levanter* (1972), and *The Care of Time* (1981). During World War II (1939-1945), Ambler made educational films for the British Army. He continued writing for motion pictures after the war. His screenplays include *The Wreck of the Mary Deare* and *The Cruel Sea.* His autobiography, *Here Lies,* was published in 1986. Ambler was born in London. David Geherin

Ambrose, Saint (340?-397), was a bishop of Milan and one of the most influential people of his time. As bishop, he acted as an adviser for three Roman emperors and defended the freedom of the church from government interference.

Ambrose preached widely. He also wrote essays promoting Christian ethics and upholding the ideal of virginity. In *Concerning Faith* (377), Ambrose defended the belief in the divinity of Jesus Christ against the ideas of the Arians, who believed only God the Father was completely divine (see **Arianism**). Ambrose also helped defeat an attempt to regain government approval of the ancient Roman religion. Historians believe that Ambrose popularized the practice of singing hymns in church. His sermons and piety inspired Saint Augustine to convert to Christianity. Ambrose baptized Augustine in 387.

Ambrose was born in what is now Trier, in western Germany. He pursued a career as a lawyer and provincial governor. The people of Milan chose him as bishop in 374. His feast day is December 7. Marilyn J. Harran

Ambrosia, *am BROH zhuh,* was a magical substance eaten by the gods of Greek and Roman mythology. Ambrosia was eaten with nectar, the drink of the gods. A human being who ate ambrosia and drank nectar became immortal. The word *ambrosial* means *sweet-smelling* or *delicious.* Mary R. Lefkowitz

Ambrozic, Aloysius Cardinal (1930-), was appointed a cardinal of the Roman Catholic Church by Pope John Paul II in 1998. The pope had appointed him archbishop of Toronto in 1990.

Aloysius Matthew Ambrozic was born in Gabrje, Slovenia, then part of Yugoslavia. He settled in Canada in 1948 and studied for the priesthood at St. Augustine's Seminary in Scarborough, Ontario (now part of Toronto). He was ordained a priest in 1955. He served as a professor at St. Augustine's from 1960 to 1967 and dean of students from 1971 to 1976. He also taught at the Toronto School of Theology from 1970 to 1976.

Ambrozic became auxiliary bishop of the archdiocese of Toronto in 1976 and coadjutor archbishop in 1986. He wrote *The Hidden Kingdom* (1972) and *Remarks on the Canadian Catechism* (1974). Robert P. Imbelli

Ambulance is a vehicle that is designed to transport sick or injured people. Most ambulances are built from specially designed automobile vans or trucks. They are painted with crosses and other special markings, and

© Larry Mulvei, SPL from Photo Researchers

Ambulances are staffed by trained medical workers called *paramedics.* Paramedics provide emergency care to patients before they reach the hospital.

they have sirens and flashing lights to warn drivers and pedestrians of their approach. Airplanes and helicopters also may serve as ambulances. Airplanes can travel long distances quickly, and helicopters can reach places that have no roads or landing strips.

The first ambulances were horse-drawn wagons that carried sick or wounded soldiers in wartime. The Spaniards used such vehicles during the siege of Málaga in 1487. In 1869, Bellevue Hospital in New York City began to use the first civilian ambulances. During World War II (1939-1945), armies first used helicopters to transport wounded soldiers from remote battlefields.

Until the 1970's, ambulances merely carried patients to a hospital. The vehicles were too small to allow any treatment and they carried little medical equipment. Most ambulance workers received only basic first-aid training and could not handle serious emergencies.

Today, most ambulances have room for treatment of patients, and they carry equipment that helps ambulance workers keep patients alive. This equipment includes bandages, oxygen masks, *resuscitators* (breathing machines), splints, and medications. In addition, many ambulances are staffed by highly trained workers called *paramedics.* Paramedics can provide *cardiopulmonary resuscitation* (CPR) and other lifesaving emergency treatments (see **Cardiopulmonary resuscitation**).

Many ambulances carry a two-way radio, which enables a worker to communicate with a hospital physician. The worker reports such information as a patient's pulse, blood pressure, and breathing condition, and the doctor can determine the proper treatment. Some ambulances have instruments that send the hospital medical data, such as a patient's heart activity, by a process called *telemetry* (see **Telemetry**). David R. Boyd

See also **Australia** (Transportation [picture]).

Ameba, *uh MEE buh,* also spelled amoeba, is a tiny, one-celled organism that usually can only be seen under a microscope. Amebas vary in size from about $\frac{1}{100}$ inch (0.25 millimeter) to $\frac{1}{10}$ inch (2.5 millimeters) across. Some amebas live in water and moist soil. Others live in the bodies of animals and human beings.

Only one cell makes up an ameba's whole body. The cell contains a *nucleus,* the structure that directs the cell's activities, and the *cytoplasm,* jellylike material around the nucleus. A thin, elastic membrane surrounds the cytoplasm and nucleus and holds them together. Water and gases pass in and out of the ameba through the membrane.

To move about, an ameba must change its body shape. The cytoplasm pushes out the membrane to form a fingerlike *pseudopod* (false foot), and all of the cytoplasm seems to flow into it. For every "step," another pseudopod must form. Cells that move in this way are called *ameboid cells.* The white blood cells of human beings are ameboid cells.

Oxford Scientific Films from Animals Animals

Ameba

Amebas eat tiny living organisms and particles of dead and decaying matter. They engulf their food by slowly wrapping pseudopods around a food particle. In this way, the food gets inside the cell. The section of the cell that contains the food is called a *food vacuole.* It floats in the cytoplasm until the food is digested. All undigested food passes out of the cell as the ameba slowly moves away. Amebas in fresh water must control water taken into their bodies or they will burst. They have a *contractile vacuole* to collect the extra water that builds up in the cell. When the contractile vacuole is filled, it empties through the cell membrane.

Amebas reproduce by *fission* (splitting apart) when they reach a certain size. The nucleus divides first. Then the rest of the body divides. The division results in two *daughter cells,* which can also grow, feed, and divide.

Most amebas are harmless to people. But one type causes a serious ailment called *amebic dysentery* when it gets into the large intestine. Lawrence C. Wit

Scientific classification. Amebas belong to the kingdom Protista. A common ameba is *Amoeba proteus.* The ameba that causes dysentery is *Entamoeba histolytica.*

See also **Dysentery; Protoplasm; Protozoan.**

Amendment, in legislation, is a change in a law, or in a bill before it becomes a law. Bills often have amendments attached before a legislature votes on them.

Amendments to the Constitution of the United States may be proposed in two ways:

(1) If two-thirds of both houses approve, Congress may propose an amendment. The amendment becomes a law when ratified either by legislatures or by conventions in three-fourths of the states.

(2) If the legislatures of two-thirds of the states ask for an amendment, Congress must call a convention to propose it. The amendment becomes a law when ratified either by the legislatures or by conventions in three-fourths of the states. This method has never been used.

For the text of amendments to the U.S. Constitution, see **Constitution of the United States.** Peter Woll

America is the great land mass of the Western Hemisphere. For location, see World (map). It is made up of North and South America. The mainland of America is the longest north-to-south land mass on earth. The greatest distance of its mainland from north to south is about 8,700 miles (14,000 kilometers), from the Boothia Peninsula in Canada to Cape Froward in Chile. The westernmost point of mainland America is at the Seward Peninsula on the west coast of Alaska. Northeastern Brazil is the easternmost point. America also includes many islands north, south, east, and west of the mainland. North and South America are connected by a land bridge that is narrowest at the Isthmus of Panama.

Many scientists believe that America was connected to the western edge of Africa and Eurasia from about 250 million years ago until about 200 million years ago. Volcanic formations in Brazil are similar to such formations in South Africa. Likewise, the Appalachian Mountains of North America may be related to the Caledonian Mountains of Scotland.

The word *America* is believed to be in honor of the Italian explorer Amerigo Vespucci. It was first used only for South America but was later applied to the whole Western Hemisphere. Today, the term is often used to refer to the United States of America.

John Edwin Coffman

America is one of the national hymns of the United States. The words were written in 1831 for a church school in Boston by Samuel Francis Smith, who was then studying for the ministry. The song was first sung at the school's Fourth of July celebration that year. Smith wrote the words to a melody that was popular in many European countries. He found the tune in a collection of German melodies. "God Save the Queen," the British national anthem, uses the same melody. Smith wrote five stanzas. The third, which called the British "tyrants," is not sung today. See also God Save the Queen.

Valerie Woodring Goertzen

America First Committee, founded in September 1940, was the most powerful isolationist group in America before the United States entered World War II. It had over 800,000 members, who wanted to keep America neutral. It tried to influence public opinion through publications and speeches. America First disagreed with another powerful group, the Committee to Defend America by Aiding the Allies. Both of the groups wanted to build American defenses and keep the United States out of the war. However, the Committee to Defend America argued that the best way to remain neutral was to aid the United Kingdom. America First thought it more important to stay out of the war than to assure a British victory. America First was dissolved four days after the Japanese attacked Pearl Harbor on Dec. 7, 1941.

David A. Shannon

America the Beautiful, also called *O Beautiful for Spacious Skies,* is one of the most familiar and popular American patriotic songs. Katharine Lee Bates, a college professor, wrote the words as a poem during a visit to Colorado in 1893. She was inspired by the view from Pikes Peak. The poem, which describes the wonders of America, was published on July 4, 1895. Sometime after that the words became associated with the hymn tune "Materna" (also called "O Mother Dear, Jerusalem"), written by American composer Samuel Augustus Ward in 1882. The music and text were published together in 1910. Katherine K. Preston

See Bates, Katharine Lee.

American Academy and Institute of Arts and Letters is an organization that promotes literature and the fine arts in the United States. It gives awards and prizes to notable artists, writers, and composers. In addition, it organizes exhibitions of art and manuscripts, and buys works by American artists to donate to U.S. museums.

The organization consists of two divisions, the Institute and the Academy. A maximum of 250 United States citizens may be members of the Institute. They serve for life and belong to one of three departments—music, art, or literature. Membership openings result from the death of a member. After a vacancy occurs, members nominate replacements. The department and full Institute membership vote on these nominees. The candidates receiving a majority of votes in both elections become members of the Institute. The Academy consists of 50 Institute members elected for life by Academy members.

The American Academy and Institute of Arts and Letters was formed in 1976 from the merger of the American Academy of Arts and Letters, founded in 1904, and the National Institute of Arts and Letters, founded in 1898. Headquarters are in New York City. Critically reviewed by the American Academy and Institute of Arts and Letters

American Academy of Arts and Sciences. See Arts and Sciences, American Academy of.

American Association for the Advancement of Science (AAAS) is the world's largest federation of scientific organizations. AAAS has about 285 affiliated societies and academies of science, which cover the physical, life, and social sciences. Individual members of AAAS number about 134,000. Membership is open to anyone interested in achieving the objectives of AAAS.

Main objectives of AAAS are to further the progress of science, make it easy for scientists to cooperate with one another, help increase scientific freedom and responsibility, make science more effective in the promotion of human welfare, and advance education in science. AAAS publishes a weekly journal called *Science.* The association was founded in 1848. Its headquarters are in Washington, D.C. Critically reviewed by the American Association for the Advancement of Science

American Association of Retired Persons. See AARP.

American Association of University Women (AAUW) is a national organization of men and women who have a bachelor's or higher degree. It has about 140,000 members. The AAUW promotes equality, education, and personal development for women, and social reform. Members take part in study and action programs, and they support legislation relating to their concerns. The AAUW's interests include the arts, com-

munity affairs, education, and international relations.

The AAUW Educational Foundation, a division of the AAUW, offers fellowships to women for advanced study or research. The AAUW also offers to its members, branches, and state divisions grants for public service projects and studies.

The AAUW was founded in Boston in 1882 as the Association of Collegiate Alumnae. Its national offices are in Washington, D.C.

American Baptist Association was organized in 1924 through the merger of three church groups—the General Association of Baptist Churches, the Baptist Missionary Association of Texas, and a Baptist convention in Oklahoma. The churches in the association do not recognize baptism by other denominations and do not practice *intercommunion* (mutual services) with other denominations. The association believes in the equality of all members and the complete independence of local congregations. See **Baptists**.

Congregations in about 45 states belong to the association. They sponsor 2 colleges, 22 Bible institutes, 5 seminaries, and support missionary work in many parts of the world. The association has almost 1,100,000 members. Its headquarters are in Texarkana, Texas.

Critically reviewed by the American Baptist Association

American Baptist Churches in the U.S.A. is an organization of Baptist churches, associations, and religious bodies. It is a member of the National Council of Churches, the World Council of Churches, and the Baptist World Alliance. The organization sponsors colleges, theological seminaries, hospitals, retirement homes, and other institutions. It supports evangelistic, educational, agricultural, and medical missions in many other countries. The organization has about 1,500,000 members. Its headquarters are located in Valley Forge, Pennsylvania.

The organization was formed in 1907, partly to help coordinate the work of national missionary and educational bodies which the Baptist churches established in 1814, 1824, and 1832. For more information about Baptist doctrine and history, see **Baptists**.

Critically reviewed by the American Baptist Churches in the U.S.A.

American Bar Association is a voluntary organization of lawyers, judges, law students, and law teachers of the United States and its possessions. The organization's goals include promoting the administration of justice and upholding high standards of legal education and ethics.

The American Bar Association, which is often called the ABA, gives *accreditation* (official approval) to law schools. The association also publishes studies on subjects of legal and public interest, such as legal aid and prison reform. In addition, the organization provides opportunities for continuing legal education in these subjects. Many members of Congress ask the ABA for its views on current legislation. The ABA publishes the monthly *American Bar Journal,* plus about 7,800 books and pamphlets yearly on topics including business, criminal, and taxation law.

More than 400,000 men and women belong to the ABA. The ABA was founded in 1878 and has headquarters in Chicago.

American Civil Liberties Union (ACLU) is a nonpartisan organization devoted to defending the rights and freedoms of people in the United States. It works mainly by providing lawyers and legal advice for individuals and groups in local, state, and federal courts. In addition, officials of the ACLU testify before state and federal legislative committees, advise government officials, and conduct educational programs. The chief goal of the ACLU is to protect the fundamental rights of individuals as described in the Constitution of the United States. These rights include freedom of speech and protection against unfair punishment for people accused of crimes.

The ACLU has defended the constitutional rights of a wide range of individuals and groups. It played an important part in Supreme Court rulings that guaranteed legal aid to poor people. The group has supported fair treatment of *conscientious objectors,* people whose conscience does not allow them to take part in war. The ACLU has urged desegregation of schools and promoted the black civil rights movement. In 1978, the organization defended the right of a group of American Nazis to march in Skokie, Illinois. One of the current goals of the ACLU is the abolition of capital punishment. The group also calls for further restrictions on government inves-

tigative agencies and for stricter separation of church and state. In addition, it seeks greater protection for the rights of immigrants who enter the United States without the required papers, and for the rights of homosexuals and mental patients. The ACLU also supports the rights of women to have abortions.

The ACLU was founded in 1920. It has about 300,000 members. Its headquarters are in New York City.

American Eskimo dog is a small dog known for its fluffy, white coat. Breeders in the United States developed the dog during the early 1900's. It is descended from European spitz breeds. American Eskimo dogs are often called "Eskies." There are three varieties—the standard, the miniature, and the toy. Standard Eskies measure 15 to 19 inches (38 to 48 centimeters) tall at the shoulder, miniature Eskies stand 12 to 15 (30 to 38 centimeters) inches tall, and toy Eskies are 9 to 12 inches (23 to 30 centimeters) tall.

Darlyn Davison

The American Eskimo dog has a fluffy, white coat.

American Eskimo dogs are intelligent, alert, and energetic. They once performed tricks in many American circuses but are now kept chiefly as pets and show dogs.

American Farm Bureau Federation is the largest general farm organization in the United States. More than 5 million families are members of the federation. The federation works to protect and advance the business and economic interests of farmers and ranchers by supporting educational programs, promoting favorable legislation, and sponsoring helpful services. It is an independent and voluntary organization that operates on local, state, national, and international levels. When promoting legislation, the federation works with both Democrats and Republicans.

The federation helps its members solve many problems affecting individual farm products. It works to reduce crop surpluses and to expand markets for farm products in the United States and in other countries. The federation promotes research to find new uses for farm products in the home and in industry. In many states, insurance, cooperative and group purchasing of farm supplies, and cooperative marketing of farm products are among its most important services. The federation also promotes farm safety, citizenship, leadership training, education, and social and community betterment.

Organization. The American Farm Bureau Federation is composed of state Farm Bureaus from all of the states and from Puerto Rico. The state bureaus are composed of county bureaus, and county bureaus are composed of farm and ranch families.

Each year, delegates from the states meet at the federation's national convention to determine the organization's policies and program of action. All the delegates are farmers whose chief occupation and interest is farming or ranching. The delegates elect a board of directors and a president and vice president. Directors and officers carry on the federation's affairs between conventions. The directors represent all sections of the United States. These officials are responsible to the federation delegate body for their activities.

The American Farm Bureau Federation has its national headquarters in Park Ridge, Illinois. It also has an office

in Washington, D.C. The federation publishes a weekly newsletter. Most of its state bureaus also publish magazines or newspapers.

History. A group of 28 state farm bureaus formed the American Farm Bureau Federation in Chicago in 1919. The federation played an important part in developing farm legislation during the Great Depression of the 1930's. This legislation emphasized soil conservation programs, price supports, and acreage control regulations. After World War II ended in 1945, the federation recommended changes in government farm programs. The changes were intended to reduce the farmers' dependence on crop price supports and acreage controls.

American Federation of Arts. See Arts, American Federation of.

American Federation of Government Employees (AFGE) is a union of civilian employees of the United States government and the District of Columbia. The AFGE represents general office workers, janitors, lawyers, mechanics, and scientists. The union consists of about 1,300 local unions called *lodges.* It is associated with the American Federation of Labor and Congress of Industrial Organizations (AFL-CIO).

The AFGE was formed in 1932 by workers who withdrew from a similar union, the National Federation of Federal Employees (NFFE). In 1931, the NFFE had broken its ties with what was then the AFL. NFFE members who wanted to have an association with the AFL then founded the AFGE. AFGE headquarters are in Washington, D.C. For membership, see **Labor movement** (table: Important U.S. labor unions). James G. Scoville

American Federation of Labor and Congress of Industrial Organizations (AFL-CIO) is a federation of labor unions. The AFL-CIO consists of many national and international craft and industrial unions that together have millions of members. The national unions are self-governing, but cooperate with one another within the federation. Each national union has local unions in the United States and its territories. The international unions also have local unions in Canada and in Puerto Rico, Panama, and other Caribbean lands. Altogether, the national and international labor unions have tens of thousands of local unions.

Organization. All the affiliated unions are represented at the AFL-CIO's conventions, held every two years. The convention is the supreme governing body. It elects the president, the secretary-treasurer, the executive vice president, and a number of vice presidents who make up the executive council. The council determines AFL-CIO policy between conventions and carries out policies established by the convention. The AFL-CIO has *central bodies* (federations) in all 50 states and Puerto Rico, and hundreds of local central bodies. It also has a number of directly affiliated local unions.

Nine trade and industrial departments are affiliated with the AFL-CIO. These departments are the Building and Construction Trades, Metal Trades, Union Label and Service Trades, Maritime Trades, Industrial Union, Food and Allied Service Trades, Professional Employees, Transportation Trades, and Public Employees departments. The national and international unions affiliate with the department or departments that represent their interests.

The AFL-CIO has a number of committees and departments. These groups deal with such matters as organizing, legislation, civil rights, ethical practices, international affairs, education, economic policy, community services, and occupational safety and health.

Activities of the AFL-CIO include working with unions to increase their membership, informing union members about legislative and political matters, providing legal assistance, and representing the interests of workers' families. In the legislative field, the AFL-CIO works for enactment of desired legislation on national and state levels. The organization promotes the activity of union members in such projects as campaigns for voter registration and for improvements in education and training. It also works to resolve certain types of disputes among its member unions. The AFL-CIO's publications include *The AFL-CIO News,* published every other week, and a weekly newsletter, *Work in Progress.*

History. In 1881, in Pittsburgh, a group of trade unionists representing about 50,000 members founded the Federation of Organized Trades and Labor Unions of the United States and Canada. In 1886, the group reorganized, changing its name to the American Federation of Labor. Its approach was to organize workers by crafts and skills. In 1935, eight leaders of AFL unions set up the Committee for Industrial Organization to carry on an organizing drive in mass-production industries. The CIO tried to sign up all workers in a plant, unskilled as well as skilled. Because of a disagreement over this type of organizing, the AFL suspended 10 national unions participating in the CIO in 1936. The CIO then formed its own labor federation in 1938 and changed its name to the Congress of Industrial Organizations. The AFL and the CIO formally merged in 1955. In 1957, the Teamsters Union, then the largest union in the United States, was expelled from the AFL-CIO after its leaders were accused of unethical practices. The Teamsters rejoined in 1987. Another of the country's largest unions, the United Automobile Workers, disaffiliated in 1968 but rejoined in 1981. AFL-CIO headquarters are in Washington, D.C.

American Federation of State, County, and Municipal Employees is one of the largest unions in the United States. It represents public employees and health care workers. The union has more than 1.2 million members. They include employees of state, county, and municipal governments; school districts; public and private hospitals; universities; and nonprofit agencies. Health and hospital workers form the largest occupational group, with more than 325,000 members.

The union's chief goal is to improve working conditions and achieve dignity for its members through collective bargaining with employers. It has over 4,000 local unions and is affiliated with the American Federation of Labor and Congress of Industrial Organizations.

The organization was founded in 1936. Its headquarters are in Washington, D.C. For membership, see Labor movement (table: Important U.S. labor unions).

American Federation of Teachers is a union affiliated with the American Federation of Labor and Congress of Industrial Organizations (AFL-CIO). It is made up of various educational workers, including teachers, counselors, school custodians, and school-bus drivers. It also represents state employees, faculty at colleges and universities, and nurses. The American Federation of Teachers has about 2,200 local unions in the United States and other countries.

The union's chief objectives are to promote professionalism in teaching and to secure appropriate wages, better working conditions, and job security for its members. The union supports school-based management, better school construction, and equal educational opportunities for people of all races. The federation upholds the rights of teachers to help form school policies and programs. Its members believe it can achieve its goals through democratic discussions between teacher representatives and school administrators, and through collective bargaining.

The American Federation of Teachers was founded in 1916. Its headquarters are in Washington, D.C. For membership, see Labor movement (table: Important U.S. labor unions).

American foxhound is a medium-sized hunting dog. It is trained to hunt foxes by following the scent they leave on the ground. Hounds can be trained to hunt singly or in packs of 15 or 20. Most hunt clubs use packs of foxhounds. American foxhounds are trained to run competitively at field trials. They are well known for their speed, endurance, and stamina in the field.

Foxhounds are usually white, with different-sized patches of black or tan or both. But a foxhound can be almost any color. The American foxhound stands from 21 to 25 inches (53 to 64 centimeters) tall at the shoulder and weighs 60 to 70 pounds (27 to 32 kilograms). It has well-shaped legs, hard muscles, a long tail, ears that hang down, and a distinctive bark. See also Dog (picture: Hounds); English foxhound.

An American foxhound is a medium-sized hunting dog. Most foxhounds have a white, black, and tan coat. The dog uses its speed, endurance, and sensitive nose to help people hunt foxes.

American Friends Service Committee (AFSC) is a Quaker organization committed to nonviolence and social equality. The AFSC promotes peaceful policies that respect human rights and the rights of nations to choose their own future. The AFSC has played a prominent role in efforts to end racial separation in South Africa. In addition, the AFSC carries out programs in developing countries that help people raise food and improve health conditions.

Quakers, who started the AFSC, believe in the equality of all people. In the United States, the AFSC works for fair treatment of American Indians, farm laborers, racial minorities, gay and lesbian people, immigrants, and others who experience poverty or discrimination.

The AFSC was founded in 1917 with the aim of caring for civilian victims of World War I. In 1947,the AFSC was awarded the Nobel Peace Prize for its relief work after World War II. The AFSC is privately funded by individuals from many religious backgrounds. It operates assistance programs in 30 countries. The organization's headquarters are in Philadelphia.

American GI Forum of the United States is a civil rights organization for Mexican American military veterans and their families. It fights discrimination against Mexican Americans in education, employment, and housing.

Hector P. García, a World War II combat surgeon, founded the organization in 1948 in Corpus Christi, Texas. The previous year, an undertaker in Three Rivers, Texas, refused to rebury a Mexican American GI who had been killed during the war and buried overseas. García and other veterans organized the American GI Forum of the United States to aid needy and disabled veterans who encountered such prejudice after the war. The group sponsors programs to help Mexican Americans obtain jobs, medical services, and scholarships.

The American GI Forum of the United States has about 50,000 members, with local chapters in nearly every state. Its national headquarters are in Austin, Texas. Feliciano M. Ribera

American Indian. See Indian, American.

American Indian Movement (AIM) is a civil rights organization in the United States and Canada. It works for equal rights for American Indians and improvement of their living conditions. The group has participated in efforts to establish Indian land ownership rights.

The American Indian Movement has often been critical of the Bureau of Indian Affairs, a U.S. government agency that works to promote the welfare of the nation's Indians. AIM believes the bureau has failed to eliminate widespread job and housing discrimination and poverty

among Native Americans. The organization also has demanded the return of property rights guaranteed by treaties between the U.S. and Canadian governments and various Indian tribes.

AIM was founded in Minneapolis in 1968 by Dennis Banks, George Mitchell, and Clyde Bellecourt. Its original goals were to help improve the lives of the city's Indians and to protect them from police actions that AIM considered brutality. AIM chapters began to be formed in other cities in 1970. AIM has carried out several protests to call national attention to the problems of Indians. In 1972, members occupied the headquarters of the Bureau of Indian Affairs in Washington, D.C., for seven days. The following year, AIM members and other Indians seized the village of Wounded Knee, S. Dak., where the U.S. Cavalry massacred as many as 300 Sioux in 1890 (see **Wounded Knee**).

During the 1970's, AIM also established and operated a number of organizations to help Indians develop a sense of self-determination. These groups, consisting only of Indians, worked to improve schools, legal services, employment programs, and health services for Native Americans. Since 1974, AIM has attempted to unite Native Americans throughout the Western Hemisphere. But problems among AIM leaders contributed to the group's decline in the 1980's. W. Roger Buffalohead

American Institute of Aeronautics and Astronautics is a professional society for engineers and scientists who are engaged in aviation and space work in the United States. The institute encourages research and aids education in the fields of science and engineering. It sponsors technical meetings and discussions, and it publishes six journals, two book series, and a monthly magazine. The institute was established in 1963 through the consolidation of the American Rocket Society and the Institute of the Aerospace Sciences. It has more than 70 corporate members and more than 44,000 professional and student members. Headquarters are in Washington, D.C. Critically reviewed by the American Institute of Aeronautics and Astronautics

American Kennel Club (AKC) is the world's largest registry for purebred dogs. The club recognizes 137 breeds of purebred dogs and registers more than 1 million dogs a year. It maintains a file called the Stud Book, which contains a family history of every dog ever registered with the AKC.

The AKC is made up of about 500 member dog clubs in the United States. The national member breed clubs set the standards by which dogs are judged at AKC shows. Representatives from the clubs carry out the AKC's activities. The AKC makes rules for dog shows and such competitions as obedience trials, field trials, and hunting tests. The AKC also approves dog show judges and maintains a staff to assist at competitions.

The AKC encourages interest in purebred dogs and promotes their health and welfare. The club publishes a number of periodicals, including the monthly magazine *Pure-Bred Dogs—American Kennel Gazette;* and *Stud Book Register,* a monthly listing of male and female dogs that have bred for the first time. It publishes the reference books *The Complete Dog Book* and *AKC Dog Care and Training.*

The AKC also produces videos on each breed and on other subjects of interest to dog owners. In addition, the AKC maintains a library and a museum.

The AKC was founded in 1884. Its headquarters are in New York City. Critically reviewed by the American Kennel Club

American League. See **Baseball**.

American Legion ranks as the largest veterans' organization in the United States. Men and women who served honorably in the U. S. armed forces during World War I, World War II, the Korean War, the Vietnam War, the Persian Gulf War, or in military actions in Grenada, Lebanon, or Panama, may join the American Legion. The Legion seeks to advance the aims and interests of veterans, to continue friendships formed during military service, and to see that disabled veterans get the care and help they need. It takes part in programs that promote the American way of life at the local, state, and national levels. It also sponsors patriotic community projects and educational and charitable programs.

The American Legion has about 3 million members. They are organized into 58 departments and about 16,000 local posts. It holds a convention each year to determine policies and programs and to elect national officers, including a national commander. The national adjutant heads the national headquarters staff at 700 N. Pennsylvania Street, Indianapolis, IN 46204. The Legion also has a national office in Washington, D.C. The official publication is the *American Legion Magazine.*

Activities. Legion posts have built community houses, swimming pools, playgrounds, and many parks throughout the United States. They have supplied ambulances and special equipment for community hospitals and for hospitals operated by the Department of Veterans Affairs. The Legion became particularly active in education during economic depressions during the early 1920's and early 1930's. More than 1,000 posts received certificates of honor from the National Education Association for keeping local schools running in spite of the reduced budgets with which they had to operate. The American Legion originated the yearly observance of American Education Week (see **Education Week, American**).

American Legion
Legion emblem

The Legion has actively opposed Communism, fascism, and all forms of totalitarianism. Its program of youth activities works to build American ideals. The Legion sponsors youth baseball leagues in all parts of the country. Each year, American Legion posts sponsor more than 4,000 baseball and other athletic teams.

The Legion sponsors more than 1,400 Boy Scout troops. Each year, the Legion holds a national high school oratory contest to promote the study of the United States Constitution and the Bill of Rights. It awards $60,000 in scholarships to the finalists. The Legion also sponsors an annual Boys State. Under this program, boys selected by local Legion posts and civic, religious, and educational organizations take part in a one-week course on the practical operation of state government. The program also includes health and

recreational activities. Boys who have taken part in Boys State are selected to attend the Legion's annual Boys Nation. This is a program in the study of national government (see **Boys State**). In national defense, the Legion has always favored adequate military preparedness.

History. A group of 20 officers who served in the American Expeditionary Forces (A.E.F.) in France in World War I is credited with planning the Legion. A.E.F. headquarters asked these officers to suggest ideas on how to improve troop morale. One officer, Lieutenant Colonel Theodore Roosevelt, Jr., proposed an organization of veterans. In February 1919, this group formed a temporary committee and selected several hundred officers who had the confidence and respect of the army.

When the first organization meeting took place in Paris in March 1919, about 1,000 officers and enlisted men attended. The meeting, known as the Paris Caucus, adopted a temporary constitution and the name *The American Legion.* It also elected an executive committee to complete the organization work. It considered each soldier of the A.E.F. a member of the Legion. The executive committee named a subcommittee to organize veterans in the United States.

The Legion held a second organizing caucus in St. Louis, Mo., in May 1919. It completed the constitution and made plans for a permanent organization. It set up temporary headquarters in New York City, and began its relief, employment, and patriotism programs.

Congress granted the Legion a national charter in September 1919. The first national convention, held in Minneapolis, adopted a permanent constitution and elected officers to head the organization.

In 1921, the country plunged into a short, sharp economic depression. Millions lost their jobs. About 4 million soldiers had returned to civilian life. The Legion turned itself into a nationwide employment service, with 11,000 branch offices. Veterans reported at Legion posts for jobs. More than 1 million people found jobs in this way. The Legion also began its fight for the relief of wounded and disabled soldiers. It organized a rehabilitation service to help disabled veterans make claims for compensation and obtain medical care. At the close of World War II, the Legion helped write the GI Bill of Rights and worked for its adoption by Congress.

Until 1942, membership in the Legion was limited to American soldiers, sailors, marines, and nurses who had served on active duty during World War I. In 1942, the Legion amended its charter to allow World War II veterans to join. Korean War veterans became eligible in 1950, Vietnam War veterans in 1966, and Persian Gulf War veterans in 1991. Veterans of the actions in Grenada, Lebanon, and Panama became eligible in 1990.

During and after the Vietnam War (1957-1975), the legion promoted job opportunities for returning veterans. It also worked to increase veterans' benefits under the GI Bill to meet rising educational costs.

American Legion Auxiliary is the largest women's patriotic organization in the United States. It is affiliated with the American Legion. Women eligible for membership are (1) wives, mothers, sisters, and female descendants of American Legion members; (2) wives, mothers, sisters, and female descendants of men and women who died in World Wars I and II, the Korean War, the Vietnam War, the Persian Gulf War, and the military conflicts in Grenada, Lebanon, and Panama, or of men and women who died after they were honorably discharged from the armed services; (3) female military veterans eligible for membership in the American Legion; and (4) female members of the Legion. The Auxiliary has nearly 1 million members in more than 12,000 local units.

Auxiliary emblem

The Auxiliary conducts programs to benefit veterans, their families, and the community. It sponsors Girls State, an annual program that educates high school girls about American government and citizenship (see **Girls State**). The first national American Legion convention in 1919 authorized the formation of the Auxiliary. The organization held its first convention in Kansas City, Mo. in 1921. The Auxiliary's headquarters are at 777 N. Meridian Street, Indianapolis, IN 46204.

American Liberty League. See **Liberty League**.

American Library Association (ALA) is an organization founded in 1876 for libraries, librarians, library trustees, and other people interested in libraries. It works closely with organizations in the fields of education, recreation, and public service. The association's 50,000 members include individuals and libraries from all parts of the world.

The ALA aims to improve the quality and effectiveness of libraries. It seeks to make libraries accessible to all people, to improve professional standards of libraries and librarians, and to promote the distribution of books and other library materials without censorship. The ALA presents several awards and citations for outstanding achievements in librarianship and related fields. Its Association for Library Service to Children awards the Caldecott and Newbery medals for children's books (see **Caldecott Medal; Newbery Medal**).

The association works for legislation to increase the availability or to improve the quality of library service. It urged passage of the Library Services Act of 1956, which was designed to aid the development of public libraries in rural areas. In 1964, the act was amended and became known as the Library Services and Construction Act. This and later amendments authorized aid to both urban and rural libraries. After a new copyright law was enacted in 1976, the association helped librarians and library users understand the law's provisions.

The ALA publishes books and periodicals. Its official bulletin, *American Libraries,* is published 11 times a year. Other periodicals include *Booklist, Choice, College and Research Libraries, Library Resources and Technical Services, RQ,* and *School Library Media Quarterly.* The ALA publishes an annual yearbook on library and information services. It also provides information about careers in the library field. ALA headquarters are at 50 E. Huron Street, Chicago, IL 60611.

American literature

American literature cannot be captured in a simple definition. It reflects the many religious, historical, and cultural traditions of the American people, one of the world's most varied populations. It includes poetry, fiction, drama, and other kinds of writing by authors in what is now the United States. It also includes nonwritten material, such as the oral literature of the American Indians and folk tales and legends. In addition, American literature includes accounts of America written by immigrants and visitors from other countries, as well as works by American writers who spent some or all of their lives abroad.

This article discusses the literature of what is now the United States. For information on the literature of Canada and Latin America, see the articles **Canadian literature** and **Latin-American literature**.

Beginnings of American literature

American literature begins with the legends, myths, and poetry of the American Indians, the first people to live in what is now the United States. Indian legends included stories about the origin of the world, the histories of various tribes, and tales of tribal heroes. With rare exceptions, this oral literature was not written down until the 1800's.

The earliest writing in America consisted of the journals and reports of European explorers and missionaries. These early authors left a rich literature describing their encounters with new lands and new civilizations. They publicized their adventures, described the New World, and tried to attract settlers in works that sometimes mixed facts with propaganda.

Colonial literature (1608-1764)

Colonists from England and other European countries began settling along the eastern coast of North America in the early 1600's and created the first American colonial literature. The colonies in Virginia and New England produced the most important writings in the 1600's. In the 1700's, Philadelphia emerged as the literary center of the American Colonies.

Virginia. Captain John Smith wrote what is regarded as the first American book, *A True Relation of . . . Virginia* (1608). It describes how he and other colonists established the first permanent English settlement in America at Jamestown, Va., in 1607. Smith told a version of the famous story of Pocahontas in *The Generall Historie of Virginia, New England, and the Summer Isles* (1624). The story claims that Pocahontas, the daughter of an Indian chief, saved Smith's life when her father was about to have him killed.

In *The History and Present State of Virginia* (1705), historian Robert Beverley wrote about the tragic destruction of the American Indians. To Beverley, the Indians represented possibilities for happiness, innocence, harmony, and freedom. William Byrd II, a Virginia planter, told about a 1728 surveying expedition in *The History of the Dividing Line* (published in 1841). The "line" divides the orderly society of Virginia from the less polished settlers of North Carolina.

New England. In 1620, the Pilgrims founded Plymouth Colony, the second permanent English settlement in America. Many Pilgrims belonged to a group of English Protestants called *Puritans,* who were followers of the religious reformer John Calvin. The Puritans faced persecution in England and came to America mainly to seek refuge where they could practice their religion. The Puritans were an intensely intellectual people. Soon after arriving, they began founding schools and colleges and writing and printing books. They wrote histories, sermons and other religious writings, and poetry.

Histories. The Puritans recorded their own history out of a desire to communicate with fellow believers in England, to attract new colonists, and to justify their bold move to a new country. In their histories, the Puritans portrayed their successes as evidence of God's favor and their hardships as signs of God's disapproval.

William Bradford, the second governor of Plymouth Colony, told the story of the colony in *Of Plimoth Plantation* (written between 1630 and 1651 and published in 1856 as *History of Plymouth Plantation*).

Cotton Mather was the greatest of the Puritan historians. He wrote more than 400 works on many subjects, including a defense of the witchcraft trials of the 1690's in Salem, Mass. But he poured his heart into *Magnalia Christi Americana* (1702), a religious history of New England that upholds traditional Puritan beliefs.

Religious writings. The Puritans based their religion on constant study of the Bible. Sermons began with a passage from the Bible, followed by an analysis of its meaning, and then its application to personal and community life. The greatest Puritan preacher and theologian was Jonathan Edwards. He wrote learned essays reformulating traditional Calvinist doctrines, but also defending them. Edwards' most important book is *Freedom of Will* (1754). In it, he defended the doctrine of *predestination,* the idea that God has chosen certain souls to be saved.

Poetry. Most critics today rate Edward Taylor as the best of the Puritan poets. A clergyman, Taylor composed a series of meditative poems on Scripture readings. He intended the poems to prepare his mind to preach and to celebrate Communion. His verse followed the learned style of the English metaphysical poets of the 1600's. Like them, he mingled everyday words and incidents with Biblical language and complex metaphors. Taylor's poems were not discovered until 1937 and not published until 1939.

Although life as a settler was hard, Anne Bradstreet found time to write poetry, chiefly for her father and husband. Her brother-in-law had her work printed in London as *The Tenth Muse Lately Sprung Up in America* (1650), the first volume of American poetry ever published. The resulting publicity made Bradstreet more conscious of her craftsmanship. She began experimenting with meter, imagery, structure, and theme. *Several Poems* (1678), a revised second edition, was published after her death. It includes her best poem, "Contemplations," a nature poem on the briefness of human life.

Michael Wigglesworth's *The Day of Doom* (1662) was

Donald G. Marshall, the contributor of this article, is Professor and Head of the Department of English at the University of Illinois at Chicago.

the most popular poem of colonial times. But the poem's jingling meter and threatening theme—about sinners being sentenced to hell on Judgment Day—seem quaint today.

Philadelphia was the largest city in the American Colonies by 1710. It replaced Virginia and New England as the cultural center of the emerging nation.

During the 1700's, a greater number of people learned to read, and a growing press served new literary tastes. Literature addressed such interests as politics and science. The essay, satire, and novel became important literary forms.

The publisher, statesman, and scientist Benjamin Franklin helped make Philadelphia a center of intellectual life. His *Autobiography* tells the story of how he ran away from Boston to Philadelphia at the age of 17. His rise from "rags to riches" through hard work and self-improvement became a model for American success. Franklin's writings emphasized practical intelligence and material success, balanced by charity and public service. His worldliness differed greatly from the earnest spirituality of the Puritans. Franklin's witty and often satiric proverbs made *Poor Richard's Almanac,* published yearly from 1733 to 1758, one of his most popular publications.

The revolutionary period (1765-1787)

During the 1760's, a movement to end British rule in the American Colonies began to gain strength. The United States became an independent nation by winning the Revolutionary War in America (1775-1783). Much of the literature of this period addressed issues relating to American independence.

Thomas Paine, a poor and largely self-taught Englishman, immigrated to Philadelphia in 1774. He soon became famous for his fiery essays in support of the American patriots. His pamphlet *Common Sense* (1776) called for complete independence from Great Britain. In a series of pamphlets called *The American Crisis* (1776-1783), he encouraged the rebels to persist during the darkest days of the Revolutionary War.

The French-born essayist Michel-Guillaume Jean de Crèvecoeur, also an immigrant to America, helped the colonists think of themselves as Americans rather than Europeans. One of the letters in his *Letters from an American Farmer* (1782) begins with the question "What is an American?" Crèvecoeur saw America as a new land where individuals could throw off old prejudices, suffocating social customs, and tyrannical government.

Like many writers of the 1700's, Franklin, Paine, and Crèvecoeur wrote in dignified, but plain and clear, prose. This style reached its peak in the ringing eloquence of the Declaration of Independence written by Thomas Jefferson. The same type of writing appears in the sober language of the Constitution of the United States, much of which was drafted by Gouverneur Morris. Alexander Hamilton, James Madison, and John Jay used this clear style in *The Federalist* (1787-1788), a series of public letters that persuaded New Yorkers to ratify the Constitution.

Literature of a young nation (1788-1830)

In the early years of United States independence, many American writers still patterned their writing after Europe's latest literary styles and forms. Gradually, however, American literature began to reflect American experiences.

The most successful American writer of the early 1800's was Washington Irving. He rose to fame with humorous and satiric writing about New York City and its past in the magazine *Salmagundi* (1807-1808) and in a book, *A History of New York from the Beginning of the World to the End of the Dutch Dynasty* (1809). The book is also called *Knickerbocker's History of New York* because Irving wrote it under the name Diedrich Knickerbocker. In *The Sketch Book of Geoffrey Crayon, Gent.* (1819-1820), Irving combined the style of the essay and the sketch to create the first short stories in American literature. The book includes "Rip Van Winkle" and "The Legend of Sleepy Hollow," two of Irving's most famous tales. In "Rip Van Winkle," the title character awakens from a 20-year sleep to find everything changed by the Revolutionary War. Irving's doubts about American independence, his hostility toward New England culture, and his desire to maintain cultural ties with England run through all his early writing.

The poet William Cullen Bryant adapted the style of English romantic poetry to describe the American landscape and to find moral significance in its beauty. Such poems as "Thanatopsis" (1817), "To a Waterfowl" (1818), and "To the Fringed Gentian" (1832) reflect Bryant's admiration of nature.

The Era of Expansion (1831-1870)

During the mid-1800's, the United States gained control of Texas, California, Oregon, and other Western lands. By the 1850's, the nation stretched from coast to coast. Americans moved westward by the thousands. The Indians who occupied many of these lands were forced to surrender their claims and to resettle on reservations. During this period, many American writers glorified the frontier or praised the beauty of nature. Much American literature reflected the optimism of a rapidly growing nation. But other American literature focused on the country's problems, including slavery. In 1861, the Civil War broke out between the North and South chiefly over this issue. The North won the war in 1865, and slavery was soon outlawed throughout the United States.

Two main forms of fiction were practiced by American writers in the mid-1800's: (1) the sentimental novel and (2) the romance. Other important literary forms included nonfiction prose and poetry.

The sentimental novel, which had been developed by English author Samuel Richardson in the mid-1700's, became immensely popular in the United States in the mid-1800's. This type of novel emphasized feelings and such values as religious faith, moral virtue, and family closeness. Its stress on traditional values appealed to many people during a period of rapid social and political change.

The sentimental novel also urged reform. It became the means for rousing concern about the plight of black slaves, poor people, and other unfortunate members of society. Harriet Beecher Stowe's *Uncle Tom's Cabin* (1851-1852), a powerful description of the evils of slavery, became a best seller. It combined an exciting plot, memorable characters, stirring appeals to the emotions,

and humor. Stage adaptations of the book also drew large audiences.

Louisa May Alcott's novel *Little Women* (1868-1869) was another best-selling sentimental novel. Based loosely on the author's own life, it tells the story of four sisters growing up. The story centers on the girls' home and personal life. Two of the sisters fall in love, while Jo, the heroine, develops a career as a writer.

The romance. Most people use the term *novel* to refer to any long fictional story in prose. Critics of the 1800's, however, distinguished a novel from a *romance.* A romance is a long work of fiction that is less realistic than a novel. Instead of everyday events, a romance describes exciting adventures or strange events. Writers often use the romance to explore dark passions or to examine the problem of evil.

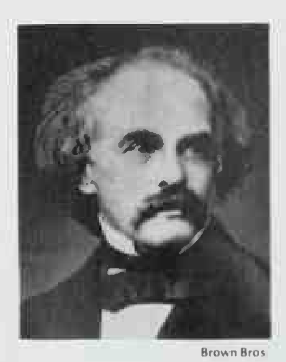
James Fenimore Cooper wrote historical romances that explored the moral uncertainties of Americans' push westward. In Cooper's romances, such as *The Last of the Mohicans* (1826) and *The Deerslayer* (1841), the beauty and majesty of nature inspire a nearly religious feeling of awe. But civilization intrudes, and settlers turn the wilderness into property that they selfishly or thoughtlessly misuse.

Nathaniel Hawthorne used the romance to study the depths of human nature. Many of his romances show the psychological effects of the Puritan focus on sin and evil. *The Scarlet Letter* (1850), set in Puritan New England, dramatizes the suffering caused by the concealment of sin.

Most critics consider the greatest American romance to be Herman Melville's *Moby-Dick* (1851). Most of the story is set on a whaling ship. It describes the hunt for Moby Dick, a fierce white whale. Ahab, the ship's captain, has lost his leg in an earlier encounter with Moby Dick and is determined to kill the whale. Ahab eventually loses his life in the pursuit. On a symbolic level, the book describes one man's struggle against fate.

A type of romance called the *Gothic novel* influenced the American poet and short-story writer Edgar Allan Poe. The Gothic novel featured exotic settings and mysterious or supernatural happenings. These novels were called *Gothic* because they often took place in gloomy medieval castles. Poe adapted these elements in shortened form in the Gothic horror story. He filled his powerful tales with decaying castles, forbidden passions, and guilt-ridden and insane criminals. With "The Murders in the Rue Morgue" (1841), Poe invented the modern detective story.

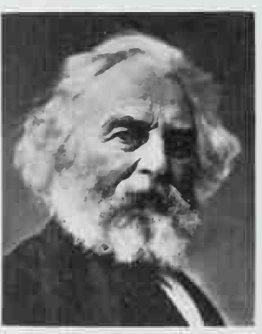
Nonfiction prose. During the 1830's and 1840's, a literary and philosophical movement called *transcendentalism* developed in New England. The transcendentalists believed that God was present in nature. They also believed that human beings intuitively know what is true, and so they stressed self-reliance and individuality. The transcendentalists included Ralph Waldo Emerson; Henry David Thoreau; George Ripley; Margaret Fuller; and Bronson Alcott, Louisa May Alcott's father.



Emerson was the leader of the movement. He kept a journal in which he recorded incidents, ideas, and reactions to his wide reading. Emerson drew on his journal in such essays as *Nature* (1836) and "Self-Reliance" (1841), achieving a prose style that was personal and conversational.

Emerson caught the mood of Americans at the time, a buoyant optimism and sense that the United States was an exciting new beginning in human history. He urged Americans to be independent thinkers and to study life directly. Emerson declared that individuals had access to the eternal and ideal truths of nature. He therefore urged Americans to trust their own creative instincts and not look to Europe for models.

In *Walden* (1854), Thoreau described his experiences living close to nature. The book tells how he built a cabin in the woods on the shore of Walden Pond in Massachusetts and lived there alone. He read, entertained visitors, worked the land for his food, and recorded his observations in journals. Thoreau's style shows his sensitive response to the root meanings, sounds, images, and nuances of words.



In 1838, Frederick Douglass escaped from slavery and fled North. During the early 1840's, he joined the abolitionists. His fiery attacks on slavery made him a famous speaker. In the first edition of his autobiography, the *Narrative of the Life of Frederick Douglass* (1845), Douglass vividly describes his life as a slave.

Poetry. During the 1800's, the most famous American poets were William Cullen Bryant, Henry Wadsworth Longfellow, James Russell Lowell, John Greenleaf Whittier, and Oliver Wendell Holmes. They were called the "Fireside Poets" or the "Schoolroom Poets" because their works were most often read "by the fireside" at home or in school in *anthologies* (collections of literary works). Like the sentimental novelists, these poets concerned

Ralph Waldo Emerson

themselves with feelings and called for social reform.

Edgar Allan Poe wrote haunting, often mournful poems. "The Raven" (1845) and "Annabel Lee" (1849) express despair over the death of a woman. Poe's poetry did not make an immediate impact on American poets. But he gained a great following in Europe after two important French poets, Charles Baudelaire and Stéphane Mallarmé, praised and translated his work. Influenced by Poe, they in turn inspired several modern American poets, including T. S. Eliot and Wallace Stevens.

Walt Whitman and Emily Dickinson were the two greatest American poets of the 1800's. Whitman took inspiration from Emerson's call for a self-confident American literature. He expressed the variety of American life in long lines that caught the flow of operatic singing. His verse often takes the form of rhythmic lists. It sprawls, seeming improvised. But Whitman also packed his poems with vivid images and memorable phrases. He wrote in *free verse,* a style of poetry that avoids regular meter and rhyme. Whitman published the first edition of his masterpiece, *Leaves of Grass,* in 1855. Five more enlarged and revised editions of the collection appeared between 1856 and 1882. *Leaves of Grass* describes the best and worst of American life, from exuberant democracy to suffering slaves. The longest poem in the collection, "Song of Myself," glorifies a spiritual life grounded in the body and everyday life.

Dickinson wrote more than 1,700 short, puzzling poems in the mid-1800's. Her subjects were love, death, nature, and immortality. Only 11 of Dickinson's poems were printed in her lifetime. After an accurate, complete edition of her poems appeared in 1955, Dickinson's reputation and influence rapidly grew. Critics admired her precise observations, her complex and unexpected images, and her questioning of established religion and authority.

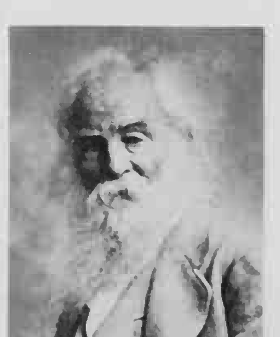
The Age of Realism (1871-1913)

The Civil War marked a dramatic change in American life. The war ended slavery, but it left the deeper problem of race relations. After the conflict, the United States turned its energies to economic concerns. Machines replaced hand labor as the chief means of manufacturing, and industry grew enormously. The new business activity centered in cities, and people moved to them in huge numbers. While some people made fortunes in business, others lived in poverty.

Realists. Many American writers of the late 1800's were inspired by an international literary movement called *realism.* Realism was in part a revolt against romanticism and its idealized portrayal of life. The realists sought to show life as it is. Realism encouraged writers to examine the problems and conditions around them and to use the language of ordinary people, including dialects. In this way, it encouraged the emergence of a distinctively American literature.

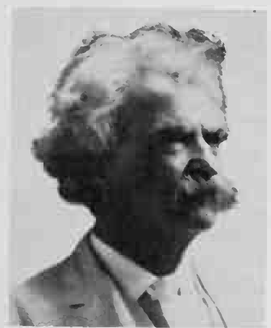
The realists explored the new economic conditions and often called for social reforms. The American dream of "rags to riches" success was captured in popular novels by Horatio Alger. But the American realists focused on the harsh underside of this dream. They feared that success brought greed, materialism, and corruption.

William Dean Howells, an influential magazine editor, vigorously argued for realism against romanticism and sentimentalism. In such novels as *The Rise of Silas Lapham* (1885) and *A Hazard of New Fortunes* (1890), he explored the impact of commercial success and failure.



Many of the realists focused on particular regions of the United States. Bret Harte portrayed the West of the gold rush in such short stories as "The Luck of Roaring Camp" (1868) and "The Outcasts of Poker Flat" (1869). Sarah Orne Jewett's *The Country of the Pointed Firs* (1896) shows a rural New England left behind by economic development.

Early Southern realists included George Washington Cable and Joel Chandler Harris. Cable's *The Grandissimes* (1880) portrays the tragic clash of races and cultures in Louisiana. Harris' *Uncle Remus: His Songs and His Sayings* (1881) and later collections of stories were immensely popular. They retell, in dialect, black folklore and stories. The black writer Charles Waddell Chesnutt's *The Conjure Woman* (1899) is also a collection of folk tales in dialect.



Naturalists were the most extreme and pessimistic realists. Unlike the realists, the naturalists believed that people could not make moral choices. They showed their characters as completely controlled by economic, social, or biological forces.

Hamlin Garland wrote bitterly of the hardships of Midwestern farmers in *Main-Travelled Roads* (1891). Frank Norris described the struggle of California farmers against the powerful railroads in *The Octopus* (1901). Upton Sinclair's *The Jungle* (1906) exposed unsanitary conditions in the Chicago meat-packing industry and

Emily Dickinson

Bettmann Archive
Mark Twain

helped bring about federal regulation.

In such stories as "The Open Boat" (1897) and "The Blue Hotel" (1898), Stephen Crane stressed the need for courage and generosity in a universe indifferent to human life. His most famous work, *The Red Badge of Courage* (1895), shows a young soldier in the Civil War, wandering in a state of shock and confusion through scenes of battle.

Theodore Dreiser was the leading American naturalist. His *Sister Carrie* traces a young woman's rise to success and social prominence despite her violation of moral codes. Her fate contrasts with her first lover's decline into poverty and suicide. Although *Sister Carrie* was printed in 1900, the publisher refused to advertise or distribute the book because his wife thought it lacked a sense of right and wrong. Another publisher issued it in 1912.

Mark Twain and Henry James are considered by critics as the two greatest American novelists of the late 1800's. Twain's *Adventures of Tom Sawyer* (1876) describes the adventures of a clever and mischievous boy and his friend Huck Finn. *Adventures of Huckleberry Finn* (1884) continues the story. It narrates the adventures of Huck and the runaway slave Jim as they float down the Mississippi River on a raft. In this book, Twain contrasts nature—where a white boy and a black man can become friends—with the hypocrisy of civilization along the shore. Twain also satirized the styles of writing that dominated earlier American literature.

Henry James left the United States in his 30's and settled in England. In his study of *Hawthorne* (1879), he argued that the lack of a rich cultural tradition made American novels thin and abstract. James wrote *novels of manners,* which first appeared in England in the late 1700's. Novels of manners depict realistic characters and scenes and describe the customs of a particular social class. In many of James's works, American characters travel to Europe, where their innocence and integrity clash with a culture that is attractive but sometimes corrupt. In *The Portrait of a Lady* (1881), a young American discovers too late the immorality of her husband, an American who has immigrated to Italy. James's style grew more complex in later novels. He traced with increasing detail the psychological and moral problems of his intelligent and self-conscious characters.

Women writers. Kate Chopin powerfully portrayed a woman's psychological and sexual development in *The Awakening* (1899). However, the hostile reaction to the novel ended Chopin's career.

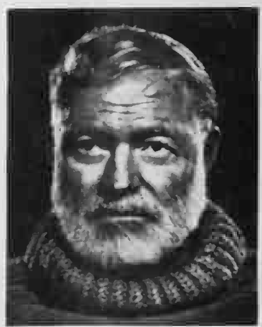
Edith Wharton was a close friend of James's. Like him, she wrote novels of manners. But many of them have American, instead of European, settings. Wharton became known for her keen moral and psychological examination of characters. *The House of Mirth* (1905) exposes the selfishness and materialism of upper-class society in New York City.

Nonfiction writers also flourished in the United States after the Civil War. The philosopher William James, brother of Henry James, wrote powerfully on many subjects, including religion and psychology. In *The Principles of Psychology* (1890), James invented the phrase *stream-of-consciousness* and thus sparked the development of a new fictional technique. In this technique, the writer tracks the shifting feelings and thoughts flowing through the mind of a character.

The economist Thorstein Veblen explored social and economic issues with biting satire in *The Theory of the Leisure Class* (1899). In *The Story of My Life* (1903), Helen Keller told how she had been helped to overcome blindness and deafness. Jane Addams' *Twenty Years at Hull House* (1912) tells of her work among Chicago's Italian, Greek, Russian, and other immigrants. As settlement in the West became more widespread, many Americans wanted to preserve the unspoiled wilderness. In *The Mountains of California* (1894) and other books, the naturalist John Muir described the American wilderness as God's temple and attacked threats to its preservation.

One of the most notable nonfiction prose writers of this period was the historian Henry Adams. In his autobiography, *The Education of Henry Adams* (privately printed in 1907, published in 1918), Adams contrasted the power of religion in the Middle Ages with the power of science in the modern world.

Two prominent black leaders disagreed on the best course for black advancement. In his autobiography, *Up from Slavery* (1901), educator Booker T. Washington urged blacks to temporarily suspend their demands for equal rights in exchange for vocational education and jobs. He predicted that blacks would achieve equal rights once they gained economic power. But historian and sociologist W. E. B. Du Bois challenged what he regarded as Washington's surrender of rights for economic gain. Du Bois refused all compromises. He insisted that "the problem of the twentieth century is the problem of the color line."



The world wars and depression (1914-1945)

In 1914, World War I broke out in Europe. In 1917, the United States entered the war against Germany, which was defeated in 1918. After the war, the United States economy boomed. But prosperity did not last. A stock market crash in 1929 led to the Great Depression, a deep economic slump in the 1930's.

In 1939, World War II began in Europe. The United States fought in the war from 1941 to 1945 and played an important role in defeating Germany and Japan.

About the time of World War I, an international artistic movement called *modernism* emerged in Europe. Modernist artists believed that the traditional social, religious, and political order had broken down. They felt that realism could not adequately describe how greatly

modern life differed from the past. As a result, they sought stylistic innovations that could better portray new realities.

The American writers who lived in Europe around the time of World War I made important contributions to modernism. Their influence extended to writers in the United States. The Great Depression led some writers of the period to focus on social or economic issues.

Modernist poetry leaves out the explanations and narrative connections that provide unity and clarity in traditional writing. It mixes everyday language with elegant phrases and short quotations from earlier poems. Modernist poets placed contradictory feelings and events side by side to evoke the disconnectedness of modern life.

Modernism was influenced by a poetic movement called *imagism,* which lasted from 1908 to 1917. Imagist poetry was characterized by precise images and a spareness of expression. The most important imagist poets were Ezra Pound, Amy Lowell, and Hilda Doolittle, who wrote under the initials H. D.

T. S. Eliot, one of the first modernists, moved to London in 1914. There, he became friends with Pound, who had already settled in Europe. Together, Eliot and Pound discovered and absorbed a wide range of poetic traditions. They developed many of the features of modernist poetry and made them well known.

Eliot mastered the modernist style in "The Love Song of J. Alfred Prufrock" (1915). His long poem *The Waste Land* (1922) created an uproar. This complex, pessimistic reflection on the emptiness of modern life seemed a masterpiece to some but bewildering to others. Eliot gradually gained a widespread influence in modern poetry. In many critical essays, he redefined the way people thought about literature.

Pound's long poem *Cantos,* published in several installments from 1925 to 1968, reflects on poetry and the course of European and American history. Pound was also important as a critic, vigorously promoting a wide range of ancient and modern poets.

Several important modernist poets emerged in the United States. Hart Crane's *The Bridge* (1930) weaves American images and themes, such as the Brooklyn Bridge, into a visionary modernist poem. Wallace Stevens's philosophical poems explore the relation of imagination to reality.

A group of Southern poets used the modernist style to encourage the preservation of traditional Southern culture. These poets included Allen Tate, John Crowe Ransom, and Robert Penn Warren. They were called the *Fugitives* because of their contributions to the poetry magazine *The Fugitive,* published from 1922 to 1925.

William Carlos Williams celebrated everyday objects and experiences in short poems and an epic, *Paterson* (1946-1958). He favored a clean, direct style that would capture the individuality of the subject matter. E. E. Cummings experimented with the physical form of poems, particularly punctuation, capitalization, and spacing on the page.

Realist poetry. Some poets of the early and mid-1900's practiced realism rather than modernism. Edwin Arlington Robinson's best poems are realist portraits of bleak and wasted lives in a New England village. In Edgar Lee Masters' *Spoon River Anthology* (1915), the now-dead inhabitants of an imaginary Midwestern town tell their life stories. Vachel Lindsay used strong, chant-like rhythms in such poems as "General William Booth Enters into Heaven" (1913) and "The Congo" (1914). Carl Sandburg was influenced by Whitman in his use of plain, everyday language. He aimed to help readers understand the lives of common people. Robinson Jeffers undertook such themes as human corruption and industrial society's destruction of nature.

The poems of Robert Frost, such as "Mending Wall" (1914) and "Stopping by Woods on a Snowy Evening" (1923), are simple and readable on the surface. But they reveal complex feelings, often through subtle irony and dry wit. Frost expressed in ordinary language the puzzling hints of doubt and uncertainty that haunt everyday incidents. These feelings connect him to modernism, despite his traditional meter, rhyme, and verse forms.

Paul Laurence Dunbar was perhaps the first black American to achieve national recognition as a writer of both poetry and fiction. Many of his poems use standard English and traditional meter, but he achieved greater fame for his portraits in dialect of black life in the South.

The Lost Generation. A number of writers joined the flourishing arts community in Paris after World War I. Many of these newcomers to Paris gathered around the novelist and critic Gertrude Stein, who had settled there before the war. She described these disillusioned writers as a "lost generation." Her experiments with prose rhythm, fractured sentence structure, and disconnected narrative were challenging and influential.

Two of the most important writers of the Lost Generation were Ernest Hemingway and F. Scott Fitzgerald. Hemingway's *The Sun Also Rises* (1926) describes these uprooted Americans in a desperate search for something to believe in after the destruction caused by the war. In short stories that some critics still consider his finest work, Hemingway crafted a bare, blunt prose that sought to clear away the emptiness of old ideas and values. His prose style has inspired many imitators.

Fitzgerald focused on American life in the Roaring Twenties, also called the Jazz Age. In short stories and in such novels as *The Great Gatsby* (1925) and *Tender Is the Night* (1934), he showed how the values of the American dream had been corrupted by materialism and class divisions. Fitzgerald's strong visual sense and way of composing a story into scenes showed the influence of early motion pictures.

Modernist fiction. Modernism led writers of fiction to reexamine the techniques of storytelling. Writers

began to strip away descriptions of scenes and characters, explanations, direct statements of theme, and summaries of the plot. A few writers experimented with prose styles as fragmented and difficult as some modern poetry.

Some critics regard William Faulkner as the greatest American novelist of the 1900's. Faulkner set most of his novels, such as *The Sound and the Fury* (1929) and *As I Lay Dying* (1930), in the imaginary Mississippi county of Yoknapatawpha. He saw slavery and racism as the great sins haunting Southern history. He believed the South fought heroically in the Civil War but for an evil cause. Faulkner's Southerners live with this heritage of guilt and useless, misguided nobility. Faulkner absorbed all the techniques of modernist storytelling. His style is symbolic, lyric, and sometimes eloquent. He evoked the contradictory feelings of his characters through fragmented and difficult plots. Faulkner often employed the stream-of-consciousness technique.

The Harlem Renaissance. During the early 1900's, particularly in the 1920's, black literature began to flourish in Harlem, a district of New York City. This movement became known as the Harlem Renaissance. It was also called the New Negro after the title of an anthology collected by educator and writer Alain Locke. The major writers of the Harlem Renaissance were Sterling A. Brown, Countee Cullen, Jessie Redmon Fauset, Langston Hughes, Zora Neale Hurston, James Weldon Johnson, Alain Locke, Claude McKay, and Jean Toomer.

Johnson's *God's Trombones* (1927) consists of seven black sermons set in verse. His poetry's dramatic and musical qualities also reflect his experience writing songs for the musical theater. McKay was one of the most powerful black poets. He began with poems in dialect. Later, he wrote highly formal but emotional verse, often on explosive topics. Hughes made a deliberate effort to bring the rhythms of African American music into poetry. Brown used dialect in subtly varied ways both to protest against racial prejudice and to express pride in the distinctive cultural tradition of African Americans. Cullen was mainly a lyric poet, but he sometimes used verse to protest racism.

Black prose writers also flourished during the Harlem Renaissance. Toomer's *Cane* (1923) is a sophisticated mixture of short stories, sketches, poetry, and a play. Hurston collected African American folk tales and became well known as a skilled oral storyteller. Her best-known novel, *Their Eyes Were Watching God* (1937), traces a black woman's steady growth in insight and spiritual strength. Her characters are vivid, realistic mixtures of strength and weakness. Locke wrote several nonfiction works on African American culture.

William Faulkner

Random House
Eugene O'Neill

Satirists. Sinclair Lewis' novel *Main Street* (1920) is a biting satire on small-town life in the early 1900's. *Babbitt* (1922) mocks the businessmen of such communities, ridiculing their civic boosterism and their equation of "progress" with real estate development. In 1930, Lewis became the first American writer to win a Nobel Prize for literature.

The sometimes savagely critical journalism of H. L. Mencken also satirized American life. Mencken, whose articles were collected in a six-volume series titled *Prejudices* (1919-1927), voiced his disgust with middle-class life and values. In *The American Language* (1919, with several later editions), he described and praised the American version of English.

Realist fiction. In *O Pioneers!* (1913) and *My Antonia* (1918), Willa Cather described frontier life in Nebraska. Each story in Sherwood Anderson's *Winesburg, Ohio* (1919) explores, from a psychological viewpoint, a different personality in a small Ohio town. Ole Rölvaag's *Giants in the Earth* (1927; published first as two books in 1924 and 1925 in Norway) concerns Norwegian immigrants in the Midwest. William Saroyan's novels portray the Armenian-American community in Fresno, California. Thomas Wolfe studied American morals and values in four huge, poetic novels. Each novel, beginning with *Look Homeward, Angel* (1929), is based on Wolfe's own life. James T. Farrell's *Studs Lonigan* series (1932-1935) describes the harsh life of working-class people in Chicago. One of the most powerful realist novels is John Steinbeck's *The Grapes of Wrath* (1939), which depicts the sufferings of Dust Bowl farmers who migrate from Oklahoma to California during the Great Depression. The black writer Richard Wright's *Native Son* (1940) tells the story of a poor young black man driven to brutal violence by the hatred and prejudice he meets in a white world.

During the 1920's and 1930's, many writers and critics debated the relation between literature and social or political change. Particularly because of the depression, many writers felt a responsibility to address economic and social problems. These authors often used journalistic techniques to educate a wide audience about needed reforms. Other writers, such as John Dos Passos, experimented with new forms and styles. In his trilogy *The 42nd Parallel* (1930), *1919* (1932), and *The Big Money* (1936)—published together as *U.S.A.* in 1938—Dos Passos aimed to portray American society fully and realistically. His novels include what he called Newsreels, which use newspaper headlines, words from popular songs, and advertisements to surround characters and action.

Dashiell Hammett and Raymond Chandler pioneered the "hard-boiled" detective novel during the 1930's. The hard-boiled hero is usually a tough, streetwise private detective who sometimes uses illegal methods to solve crimes.

Drama. Most American plays of the 1700's and 1800's were sentimental comedies or melodramatic tragedies. Eugene O'Neill broke this tradition in the 1920's. Early in his career, he created highly realistic plays. He wrote

about the criminals, homeless, alcoholics, laborers, artists, and radicals he had encountered in several years of drifting. These characters spoke in crude, slangy, but lively language. Gradually, O'Neill's plays grew longer, and he experimented more boldly with artistic techniques. He moved toward a more symbolic, stylized theater that could express his characters' inner emotions. He turned toward autobiographical material for his final plays, such as *Long Day's Journey into Night* (written from 1939 to 1941 and first performed in 1956) and *A Moon for the Misbegotten* (written from 1941 to 1943 and first performed in 1957).

During the 1930's, vigorous debates took place over the purpose of drama. Some playwrights wanted the theater to be a force for social reform. Others concentrated on experimental technique, and still others aimed at frankly escapist and commercially successful work. Clifford Odets' *Waiting for Lefty* (1935) and *Awake and Sing!* (1935) attack social problems of the time. Lillian Hellman's plays, such as *The Children's Hour* (1934) and *The Little Foxes* (1939), explore the destructiveness of greed, materialism, and sexual repression in American life. Elmer Rice's *The Adding Machine* (1923) is a satire on the growing mechanization of humanity. In *Our Town* (1938), Thornton Wilder used uncommon staging techniques, such as the absence of scenery or a curtain, to balance a somewhat sentimental picture of small-town New England life.

Literature since 1945

After World War II ended in 1945, the United States underwent many changes. The economy prospered, but the gulf between the rich and the poor widened. The black civil rights movement gathered strength in the 1960's. Other groups, including women, also began to demand fuller rights. The United States remained an important world power but was criticized for its participation in the Vietnam War (1957-1975) and for its influence abroad. Much American literature was concerned with these economic and social changes.

Poetry. By the 1950's, modernism was the dominant form. A generation of poets, including Robert Lowell, John Berryman, and Theodore Roethke, thoroughly mastered modernist techniques.

Variations on modernist poetry. A number of poets and groups developed poetic styles that were variations on modernism. One group, called the Black Mountain poets, gathered around Charles Olson at Black Mountain College, an experimental arts school in Black Mountain, N.C. Olson sought to give poetry a physical immediacy. In *The Maximus Poems* (1953-1975), he let the rhythm of his own breathing determine the length of his verse lines. Robert Creeley, Robert Duncan, and Denise Levertov carried forward Olson's style of verse, seeking an "open" form that could admit a range of experiences, feelings, and insights.

A group called the *beat poets* condemned the failings of American society and turned poetry into a powerful tool of social protest. The beat poets shared a disgust with false values and a desire to achieve spiritual elevation. One of the most important beat poets was Allen Ginsberg. Ginsberg's "Howl" (1956) describes spiritual ecstasy and the torments of urban life in long lines influenced by Whitman and William Carlos Williams.

Gary Snyder's poetry reflects his interest in Asian culture and in the relation of human beings to their environment. Snyder's poems are collected in *Myths and Texts* (1960), *Turtle Island* (1974), and other volumes.

Frank O'Hara led a group of poets centered in New York City. His poems read like improvised and casual records of quickly changing and scattered urban life. John Ashbery, a member of the New York group, wrote poems that reflect the influence of modern art and music. Many of his poems hint at their subject only indirectly and vaguely.

James Merrill began his career with polished formal verse, often autobiographical but highly restrained. *The Changing Light at Sandover* (1982) is a record of messages from a Ouija board, a device supposedly used to communicate with the dead.

A. R. Ammons experimented with verse form and punctuation, seeking a language to express the interaction between a scene being observed and an observer. W. S. Merwin's haunting phrases express his concern with political and ecological issues.

Elizabeth Bishop's highly regarded poems are formal and self-restrained, but express powerful personal feelings and experiences. *Questions of Travel* (1965) and *Geography III* (1976) explore themes of travel, exile, and response to exotic landscapes. Robert Penn Warren gained fame as a novelist but also wrote verse. His poems center on history, memory, and the effort to deal with time's erosive power.

"Confessional" poetry. Some poets began to write poetry, sometimes called "confessional" poetry, that was more personal and emotional. Robert Lowell's *Life Studies* (1959) and John Berryman's *77 Dream Songs* (1964) speak frankly of their troubled lives. Theodore Roethke explored the themes of growth and childhood in elegantly written poems. Sylvia Plath sometimes used the Holocaust, the mass murder of European Jews by the Nazis during World War II, as a metaphor for personal crisis. Anne Sexton wrote about her mental illness in a direct and open style. Adrienne Rich moved from formal verse to steadily deeper probings of her consciousness as a woman.

The black experience became the subject of many poets in the 1950's and 1960's. The early poetry of Gwendolyn Brooks showed her skill in traditional rhyming verse and forms like the *sonnet,* a 14-line poem with a formal arrangement of rhymes. Yet her words drew on oral black preaching and street talk. She described the

Jill Krementz

Robert Lowell

Bob Black *Chicago Daily News*

Gwendolyn Brooks

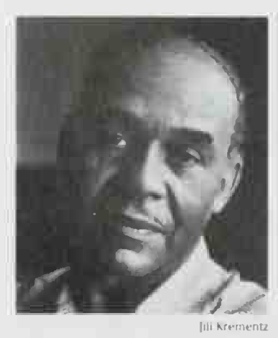
ordinary lives of blacks and the injustices they suffered.

In the 1960's, with the rise of the civil rights movement, many African Americans rejected earlier hopes for an integrated society and began to call for a separate black culture. LeRoi Jones's early poems express the personal agonies of living in a prejudiced world. But he increasingly saw the problem as social, not personal. He began to write plays and helped start the Black Arts movement. The movement rejected the literary forms and values of white culture, instead founding magazines and institutions to support writing that reflected black experience. As Jones became more politically active, he changed his name to Imamu Ameer Baraka, then to Amiri Baraka, to reflect his African heritage.

Fiction and other prose. In the postwar period, many writers continued to create realist fiction. Several authors drew their subjects from World War II, including James Jones, Norman Mailer, Irwin Shaw, and Herman Wouk. Others described regions of the country or the experiences of certain age groups or races. John Cheever and John O'Hara wrote about suburban life in New England, New York, and Pennsylvania. J. D. Salinger exposed the shortcomings of the adult world as seen through the eyes of a New York teen-ager in *The Catcher in the Rye* (1951). James Baldwin wrote about the black experience in such novels as *Go Tell It on the Mountain* (1953) and *Another Country* (1962). Ralph Ellison, in *Invisible Man* (1952), provided a haunting picture of African American life in the United States. John Updike examined the materialism of middle-class American life in the four-volume "Rabbit" series, from *Rabbit Run* (1960) to *Rabbit at Rest* (1990). Joyce Carol Oates produced a large body of fiction that ranged from realistic stories of urban life to nightmarish novels.

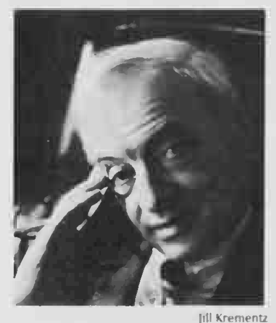
Saul Bellow is one of the most widely respected postwar novelists. His early work, such as *Henderson the Rain King* (1959), is exuberant and comic. His later novels focus on mature, thoughtful men who experience and reflect on the problems of modern life.

The beat novelist Jack Kerouac's *On the Road* (1957) tells of young rebels against the boredom and pointlessness of daily life who wander the United States in a search for meaning. Kerouac's strongly rhythmic flow of words creates an impression of spontaneity and improvisation, like that in jazz.

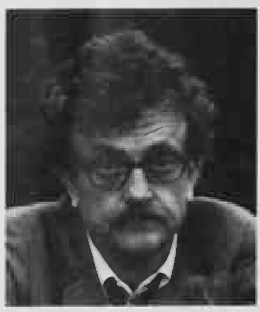


Southern fiction. A number of Southern writers, influenced by Faulkner, focused on the poor, outcasts, or grotesque characters. Among these writers were Carson McCullers and Flannery O'Connor. McCullers depicted the pain of loneliness in many of her works, including *The Member of the Wedding* (1946) and *The Ballad of the Sad Café* (1951). In brilliant short stories and in such novels as *Wise Blood* (1952) and *The Violent Bear It Away* (1960), O'Connor presented grotesque characters and disturbed behavior in a darkly comic style.

Eudora Welty sets most of her novels and short stories in her native Mississippi. In her works, comic and satiric twists lighten the impact of odd characters or moments of violence. Walker Percy was strongly influenced by European philosophy, especially a movement called *existentialism,* which stresses that individuals must choose their own way to live and act. His novels, including *The Moviegoer* (1961) and *The Second Coming* (1980), humorously take up the existential themes of alienation and the search for self-fulfillment.



Experimental styles. The stylistic experiments of the modernists opened the way for a technique called *self-reflexive fiction,* an innovative manipulation of language and narrative. Self-reflexive fiction often calls attention to the act of writing itself. For example, it may comment on or even argue with itself and address or even mock the reader. Self-reflexive fiction and other experimental techniques became common among postwar authors. In *The Sot-Weed Factor* (1960), *Chimera* (1972), and other works, John Barth created wild comedies mingling ancient myth, history, and highly unreliable autobiography.



Thomas Pynchon's massive *Gravity's Rainbow* (1973) is a fantastic reimagining of World War II filtered through the social concerns of the early 1970's. Joseph Heller's *Catch-22* (1961) and Kurt Vonnegut's *Slaughterhouse-Five* (1969) use dark comedy to satirize the self-satisfaction they felt resulted from the war. Ken Kesey's *One Flew over the Cuckoo's Nest* (1962) uses a mental hospital and a con-man hero as symbols of modern American society. The Polish-born Jerzy Kosinski's childhood experiences during World War II inspired the grotesque violence of *The Painted Bird* (1965). The same memories haunt the dark comedy of his later novels set in the United States, including *Being There* (1971).

In *Mumbo Jumbo* (1972) and other works, the black writer Ishmael Reed drew a satiric and disorienting picture of race relations and other aspects of modern life. In *Snow White* (1967), *The Dead Father* (1975), and other books, Donald Barthelme aimed to unsettle readers

by violating conventions of realistic storytelling.

John Hawkes used experimental and self-reflexive styles in *The Lime Twig* (1961) and other novels. The Russian-born Vladimir Nabokov won fame for his brilliant language and self-reflexive techniques in such novels as *Lolita* (1958; published in 1955 in France), *Pale Fire* (1962), and *Ada* (1969).

Jim Anderson, Black Star
William Styron

Some postwar writers blend fiction with historic fact. Truman Capote's *In Cold Blood* (1966) employed his powerful narrative skills to tell the story of a brutal multiple murder. Norman Mailer's best work has been journalistic and autobiographical, in particular *The Armies of the Night* (1968), about a mass demonstration against the Vietnam War. The novelist William Styron gave a fictional version of a slave revolt in Virginia in 1831 in *The Confessions of Nat Turner* (1967). E. L. Doctorow used both fictional and real-life characters in his reimaginings of American history.

Works by minority writers. The civil rights movement of the 1960's brought forth a number of popular autobiographies, including *The Autobiography of Malcolm X* (1965, edited by Alex Haley), Claude Brown's *Manchild in the Promised Land* (1965), and Eldridge Cleaver's *Soul on Ice* (1968). Haley's *Roots: The Saga of an American Family* (1976) traces his family's history back through American slaves to his African ancestors.

The black novelist Toni Morrison wrote about the lives of black women in the North in such novels as *Sula* (1973), *Tar Baby* (1981), and *Beloved* (1987). The black writer Alice Walker won fame with the novel *The Color Purple* (1982). Walker has presented a range of black characters, some heroic, but others deeply flawed, particularly black men who treat women unfairly. Like Morrison, she has increasingly found an exuberantly creative language and storytelling technique.

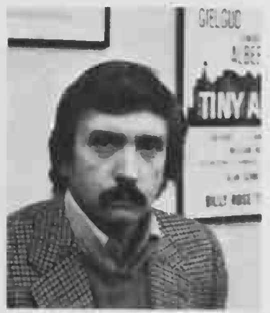
N. Scott Momaday, a writer of Kiowa and Cherokee ancestry, used varied modern narrative techniques in *House Made of Dawn* (1968), the story of an alienated American Indian veteran of World War II. *Ceremony* (1977), by Pueblo Indian novelist Leslie Marmon Silko, tells about another World War II Indian veteran. This young man, torn by the conflict between ancient Indian ways and modern white ways and shattered by his combat experiences, is gradually healed by an Indian ceremony. Maxine Hong Kingston's *The Woman Warrior* (1976) blends fiction with fact to express the complex experience of growing up as a Chinese-American woman.

Essays. Such critics as Irving Howe, Lionel Trilling, and Edmund Wilson played an important role from the 1930's to the 1950's in shaping the public understanding of literature and in popularizing important new intellectual movements. In the 1960's and 1970's, Susan Sontag tried to clarify the leading features of contemporary art.

The journalist Tom Wolfe used an exuberant, inventive style to report on popular culture during the 1960's and 1970's. His writing included cutting satire of those who pursued fashion in politics and modern architecture. Wolfe also wrote fiction, satirizing modern American culture in the novel *The Bonfire of the Vanities* (1987).

Drama. The leading playwrights after World War II were Tennessee Williams and Arthur Miller. Williams' drama often shows a conflict between sensitive, poetic individuals and the brutality and coarseness of modern life. His plays are basically realistic psychological portraits. *The Glass Menagerie* (1945) and *A Streetcar Named Desire* (1947) are his most famous. His later work explores grotesque and sometimes disturbed behavior. Miller's *Death of a Salesman* (1949) lends tragic dignity to the anguish of Willy Loman, a traveling salesman. Loman is destroyed by accepting popularity and material success as the highest values in life.

In *Who's Afraid of Virginia Woolf?* (1962), Edward Albee explored with biting wit and grotesque humor how love and cruelty are entangled within marital relationships and friendships. Albee also adapted the style of the *theater of the absurd* in plays that probed social and personal problems, such as *The Zoo Story* (1959). Theater of the absurd was a drama movement of the 1950's and 1960's that stressed the absurdity and lack of meaning the authors saw in modern life.



During the 1950's and 1960's, black theater often took up political themes. Lorraine Hansberry's *A Raisin in the Sun* (1959) is a realistic portrait of a black family who move into a white area. They must find the courage to resist white prejudice and claim the right to realize their hopes. James Baldwin's *Blues for Mister Charlie* (1964) traces the racial myths that trap both blacks and whites. The poet Amiri Baraka also wrote plays, promoting black nationalism and expressing anger at whites in such dramas as *Dutchman* (1964), *The Slave* (1964), and *Slave Ship* (1967).

August Wilson has written powerfully on the black experience in America in the 1900's in a cycle of plays. *The Piano Lesson* (1987) describes the conflict between a brother and sister over whether to sell or keep the family heirloom, a piano.

In Ntozake Shange's *For Colored Girls Who Have Considered Suicide/When the Rainbow Is Enuf* (1976), seven women dance, sing, and recite poetry. Their performances create a collage of black women's feelings and experiences.

In plays such as *The Basic Training of Pavlo Hummel* (1971) and *Sticks and Bones* (1971), David Rabe portrayed

the disillusionment of soldiers in the Vietnam War. Sam Shepard's dramas, such as *True West* (1980) and *Fool for Love* (1983), are bitter explorations of family relationships and the dominant values in American society and politics. David Mamet's plays, including *American Buffalo* (1975) and *Glengarry Glen Ross* (1983), are noted for their vigorous dialogue, often profane and rapidly exploding into arguments.

The study of American literature

During the 1920's, American literature began to become an important field in higher education. Critics and scholars such as Norman Foerster and Bliss Perry played a key role in editing texts and creating anthologies for use in classes. The need to define a *curriculum* (course of study) led to the designation of some works as "classics" every student should read. Books that did not win this designation were often neglected.

Scholars also began to seek common themes that unified and distinguished American literature. In a series of books during the early 1900's, Van Wyck Brooks stressed the features and outlook that distinguished American from European writing. Historian Perry Miller's two-volume *The New England Mind* (1939-1953) was influential in studies of literature. In that work, Miller traced American culture to the Puritan tension between commercial and religious values and between individualism and community.

Educators today have sought to broaden the definition and scope of American literature. They believe that the past study of American literature concentrated too heavily on white male writers whose works were considered "classics." Teachers and critics today pay more attention to works by blacks and other minority groups, and women. There is also greater interest in nontraditional forms of literature, including journals and other unpublished writing. Donald G. Marshall

American Lung Association is the oldest nationwide voluntary public health agency in the United States. The agency was founded in 1904 to combat tuberculosis. Today, the association, its medical arm—the American Thoracic Society—and its state and local affiliates work to control and prevent all lung diseases. In addition, the association and its affiliates work to combat some of the related causes of breathing problems, including smoking, air pollution, and occupational lung hazards.

The American Lung Association provides public health education programs and materials on such diseases as lung cancer, emphysema, asthma, pneumonia, influenza, tuberculosis, and lung disorders in infants. It supports medical research and awards grants to encourage young medical professionals to specialize in lung health. The work of the association is funded in part by public contributions to its annual Christmas Seal Campaign. Headquarters of the American Lung Association are in New York City.

Critically reviewed by the American Lung Association

American Medical Association (AMA) is a professional society of physicians. Its purpose is "to promote the science and art of medicine and the betterment of public health." Most members join the AMA through one of its state and territorial medical associations. The association's membership includes medical students and resident physicians, and representatives of government services, medical staffs, and medical specialty societies.

The AMA publishes a weekly scientific journal, the *Journal of the American Medical Association;* a weekly newspaper, *American Medical News;* monthly specialty journals; and other publications on medical subjects. The AMA was founded in 1847. Its headquarters are located in Chicago.

Critically reviewed by the American Medical Association

American Museum of Natural History, in New York City, was incorporated in 1869 for the purpose of developing the study of natural science. The museum's scientific departments conduct research programs. It also has a department of education. The museum produces several publications yearly. A research library is also located there. The Rose Center for Earth and Space, which includes the Hayden Planetarium, is directed by the museum.

The American Museum of Natural History includes exhibits on various types of animals, dinosaurs and other fossil life, as well as rare gems, minerals, and meteorites. Other exhibits illustrate human cultures and biology, and the origin of life.

Critically reviewed by the American Museum of Natural History

American Party is a conservative political party in the United States. The party was set up in 1968 under the name *American Independent Party* to support former Governor George C. Wallace of Alabama in his campaign for president. Wallace had been governor of Alabama from 1963 to 1967 and had run unsuccessfully for the Democratic nomination for president in 1964. Wallace had gained national attention by resisting the U.S. government's efforts to desegregate Alabama public schools.

The roots of the American Independent Party can be traced back to the 1960 presidential election. Six of Alabama's 11 Democratic electors in the Electoral College rejected the national Democratic candidate, John F. Kennedy. Instead, they cast their votes for Senator Harry F. Byrd of Virginia.

In 1968, Wallace's supporters succeeded in placing the American Independent Party on the ballot in every state. That year, Wallace chose retired General Curtis E. LeMay as his running mate. The party platform condemned government welfare programs, the Civil Rights Act of 1964, and what the party considered a "no-win" policy in the Vietnam War. Republican Richard M. Nixon won the 1968 election. Wallace ran far behind the Democratic candidate, Hubert H. Humphrey. However, Wallace got 13 $\frac{1}{2}$ percent of the popular vote and 46 electoral votes.

In 1969, representatives from 38 states established the American Party as the successor to the American Independent Party. In 1976, the party split into the American Party and the American Independent Party. Both of the parties have nominated candidates for the presidency and other offices. But neither party achieved the strength of the American Independent Party under Wallace's leadership. The Know-Nothing Party of the 1850's also used the name *American Party* (see Know-Nothings). Peter N. Carroll

American Printing House for the Blind is one of the world's major publishers for the blind. It produces books and magazines in braille, in large-type form, and in recorded versions. It also produces educational tools and teaching aids. It is a nonprofit corporation supported through public donations, sales to individuals and agencies, and contracts with agencies that furnish materials free or at cost. An annual appropriation by Congress is used solely for the manufacture and distribution of educational materials to blind students at lower than college level.

The American Printing House for the Blind has headquarters in Louisville, Kentucky. The Kentucky legislature established the organization in 1858. The federal government authorized its first appropriation in 1879. In 1961, the corporation, with the Field Foundation, Inc., and Field Enterprises Educational Corporation (now World Book, Inc.), published a braille edition of *The World Book Encyclopedia* (see **Braille**). In 1980, the American Printing House for the Blind and World Book, Inc., published a recorded edition of *World Book*. It included cassette tapes of the encyclopedia, a special cassette player, and indexes in both braille and large type.

American Revolution. See Revolutionary War in America.

American Samoa is a United States territory, about 2,300 miles (3,700 kilometers) southwest of Hawaii. Six of the territory's seven islands are divided among three groups—Tutuila and Aunuu; Ofu, Olosega, and Tau (the Manua group); and Rose. These islands are in the Samoan chain. The seventh, Swains Island, lies 200 miles (320 kilometers) north. The Jennings family has owned Swains Island since 1856. That year, Eli Jennings, an American, and his Samoan wife settled there.

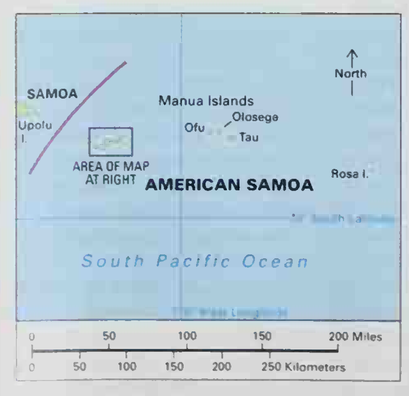
The largest and most important island is Tutuila. Pago Pago (pronounced *PAHNG oh PAHNG oh)*, the capital of American Samoa, lies on Tutuila on one of the best and most beautiful harbors in the South Pacific. Pago Pago is the territory's only port and urban center.

American Samoa's 73,000 people are nationals, but not citizens, of the United States. They may freely enter the country at any time. Many people of Samoan descent live in Hawaii and the continental United States.

Government. American Samoa is administered by the U.S. Department of the Interior. It is classified as an *unorganized and unincorporated territory*. For details, see **Territory** (In the United States). American Samoans adopted a constitution in 1960. They elect a governor to a four-year term. American Samoa has a legislature with a Senate and a House of Representatives. The Senate has 18 members chosen by county councils to serve two- to four-year terms. The House has 20 members elected by the people to two-year terms. Samoans who are 18 years old or older may vote. American Samoans elect a delegate to the U.S. House of Representatives. The delegate may only vote in House committees.

People. Almost all American Samoans are Polynesians. Samoan, a Polynesian language, is the main language, but many people also speak English. Most of the people live in villages, and their lives center around their families. Each family group is headed by a chief who controls the family's property, represents it in the village council, and takes care of its sick or aged. Most American Samoans are Christians.

In 1961, the United States began an economic development program in American Samoa. Many people left their villages to take jobs in industries around Pago Pago. Thatch-roofed *fale* (houses) were replaced by hurricane-proof concrete buildings. New schools were built, and teaching by television was introduced. Children from the ages of 6 to 18 must attend school.



Land. The islands that make up American Samoa have a total area of 77 square miles (199 square kilometers). Only a third of the land can be cultivated. Rose and Swains islands consist of coral. The others are remains of extinct volcanoes. Most of the land is mountainous, with some fertile soil in the valleys. Coconuts, bananas, and taro are grown (see **Taro**). There are few natural resources. The islands have a wet tropical climate. Yearly rainfall averages over 200 inches (510 centimeters). Temperatures range from 70 to 90 °F (21 to 32 °C).

Economy. The leading industry is tuna canning. Fish products make up over 96 percent of all exports. Other exports include handicrafts. A jet airport and a luxury hotel were built in the 1960's, and tourism increased. The U.S. government has provided large amounts of money to give American Samoa a prosperous economy.

History. The Samoa Islands have been occupied by Polynesian peoples for at least 2,000 years. These peoples probably migrated from eastern Melanesia. European explorers first reached the Samoa Islands in 1722 (see **Samoa** [History]). In 1872, the Samoans agreed to let the United States use Pago Pago Bay as a naval coaling

Pago Pago, American Samoa's capital, lies on one of the most beautiful harbors in the South Pacific. Pago Pago is the territory's only port and urban center.

station. Later, the United States was given trading rights in the islands.

In 1899, the United States, Germany, and the United Kingdom signed a treaty dividing the Samoa Islands between the United States and Germany. Germany took control of the western islands in 1900. The United States took control of Tutuila, Aunuu, and Rose Island in 1900, and the Manua group in 1904. Swains Island was annexed in 1925. The islands were administered by the U.S. Navy until 1951, when they were transferred to the Department of the Interior. Afterward, the governor of American Samoa was appointed by the secretary of the interior. In the early 1970's, the United States proposed that the territory elect its governor. But Samoan voters rejected the proposal three times. Many believed the change would weaken their ties to the United States. American Samoans approved the proposal in 1976. They elected a governor in 1977. Donald H. Rubinstein

American Samoa, National Park of, lies in the United States territory of American Samoa in the South Pacific Ocean. The park was established primarily to protect the area's tropical rain forest on the islands of Tutuila and Tau. The rain forest is home to many kinds of plants and animals, including two species of large bats called *flying foxes.* A white sand beach and a coral reef on the island of Ofu are also protected.

The national park also protects the way of life of the Samoan people. The people practice traditional methods of farming and reef fishing in certain areas of the park. The park was established in 1988. For its area, see National Park System (table: National parks).

American Society for the Prevention of Cruelty to Animals. See Society for the Prevention of Cruelty to Animals.

American Society of Composers, Authors and Publishers (ASCAP) is an association of over 100,000 writers and publishers of music. Composer Victor Herbert helped found ASCAP in 1914. The federal copyright law states that no musical work may be performed publicly without permission of the copyright owner. ASCAP is a clearinghouse between users and creators of music. Its license permits users to perform any member's music at any time without separate clearance. ASCAP collects license fees from music users and distributes the income to members and to associated societies. Royalties are distributed to members based on the nature of the performance and how often the music is used. ASCAP has mutual agreements with other performing rights societies in over 40 nations. Its headquarters are in New York City. Critically reviewed by the American Society of Composers, Authors and Publishers

American Staffordshire terrier is a breed of dog that originated in the United States. It descended from the Staffordshire bull terrier, a breed brought from England in the late 1800's. By the early 1900's, American breeders had developed a dog taller and heavier than its British ancestors. The American Staffordshire terrier has been called *Yankee terrier* and *pit bull.* It was once used in vicious dog fights in pits. The dog is still popularly called pit bull. American Staffordshire terriers stand from 17 to 19 inches (43 to 48 centimeters) tall and weigh from 45 to 65 pounds (20 to 29 kilograms). The dogs have a short, stiff coat that may be any color. They resemble bull terriers. See also Dog (picture: Terriers); Pit bull; Staffordshire bull terrier.

American Stock Exchange, also called the Amex, is one of the largest stock exchanges in the United States. It is the country's second largest *options exchange*—that is, marketplace for stock-buying rights. The Amex is also a leader in *exchange-traded funds* (ETF's), publicly traded investments similar to mutual funds.

The Amex conducts trading through an advanced *centralized specialist system.* Under the rules of the exchange, Amex specialists seek to maintain fair and orderly markets in the stocks that are assigned to them. More than 80 percent of the Amex's buying and selling orders come electronically. Other orders are initiated directly on the trading floor by registered brokers. Regardless of where an order originates, orders for any particular stock flow through a single specialist.

The American Stock Exchange started in the mid-1800's as the New York Curb Market. This organization consisted of New York City brokers who met outdoors at the curb to buy and sell stocks. In 1921, trading moved indoors into what has been the Amex's home ever since. In 1953, the organization was renamed the American Stock Exchange. The Amex became a subsidiary of the National Association of Securities Dealers, Inc., in 1998. The headquarters of the American Stock Exchange are in New York City.

American water spaniel is a hunting dog that was developed in the United States. The dog is especially helpful to pheasant and duck hunters. It *flushes* birds (forces them to fly out of their hiding place) so the hunter can shoot the birds. The dog then brings the

dead bird back to the hunter. The dog's thick, curly coat protects it from both cold water and thorny bushes. Its coat may be *liver* (reddish-brown), brown, or dark chocolate-brown in color. Some American water spaniels have white markings on the chest or toes. Most of the dogs weigh from 25 to 45 pounds (11 to 20 kilograms) and stand 15 to 18 inches (38 to 46 centimeters) at the shoulder. Critically reviewed by the American Kennel Club

See also **Dog** (picture: American water spaniel).

American's Creed won a nationwide contest for William Tyler Page of Maryland in 1917 as "the best summary of the political faith of America." It follows:

"I believe in the United States of America as a government of the people, by the people, for the people; whose just powers are derived from the consent of the governed; a democracy in a Republic; a sovereign Nation of many sovereign States; a perfect Union, one and inseparable; established upon those principles of freedom, equality, justice, and humanity for which American patriots sacrificed their lives and fortunes.

"I therefore believe it is my duty to my country to love it; to support its Constitution; to obey its laws; to respect its flag; and to defend it against all enemies."

Kenneth Janda

Americans for Democratic Action (ADA) is an independent political organization that urges government action to promote and maintain liberal policies. The ADA favors action to protect and extend civil rights, to expand programs to provide economic security for all, and to improve international cooperation. The ADA opposes United States participation in military conflicts in the developing countries. The ADA tries to influence public officials. It publishes materials to influence public opinion, and campaigns to elect liberal candidates. The ADA was founded in 1947. Its national headquarters are in Washington, D.C. Murray Clark Havens

America's Cup is the oldest trophy in international sports. It is awarded to the winner of the world's best-known sailboat competition. A yacht from a defending country races against a yacht from a challenging country. The first yacht to win a certain number of races wins the cup. Races are held on a course off the coast of the defending nation every three or four years.

The cup gets its name from the American schooner *America*. In 1851, *America* defeated 14 British yachts in a race around the Isle of Wight to win a silver trophy. The yacht's owners gave the trophy to the New York Yacht Club in New York City in 1857.

The New York Yacht Club successfully defended the cup in 16 challenges before the outbreak of World War II in 1939. In the final three prewar races, the competitors sailed large yachts called *J-Class*. Competition resumed in 1958 in a match sailed on *12-Meter* yachts, which were much smaller than the J-Class.

In 1970, two countries challenged for the cup for the first time, requiring selection trials to determine who would race the defender. In 1983, *Australia II* defeated the New York Yacht Club *Liberty* and became the first challenger ever to win the cup. In 1987, the United States yacht *Stars & Stripes* defeated Australia's *Kookaburra III* to return the cup to the United States.

Competition now operates under a code of conduct and design specifications established after a one-sided match in 1988 between a New Zealand monohull challenger and a United States catamaran defender. The new class is called *International America's Cup Class* (IACC). The yachts are designed to a formula that specifies length, weight, and sail area. The yachts are about 75 feet (23 meters) long, made of lightweight carbon fiber, and have a crew of 16.

The first challenge in IACC yachts took place off San Diego in 1992 when the U.S. yacht *America*[3] defeated the Italian challenger *Il Moro di Venezia*. In 1995, the New Zealand yacht *Black Magic* beat the U.S. defender *Young America* to become only the second challenger to win the cup. In 2000, the New Zealand yacht *Black Magic* defeated the Italian challenger *Luna Rossa*. Charles Mason

Americium, *AM uh RIHSH ee uhm* or *AM uh REES ee uhm,* is an artificially created radioactive element. Its chemical symbol is Am, and its atomic number is 95. Americium has 12 known isotopes, the most stable of which has a mass number of 243 and a half-life of 7,400 years. Only this isotope and one that has a mass number of 241 and a half-life of 432 years can be produced in large amounts. At 20 °C, americium has a density of 13.67 grams per cubic centimeter (see **Density**). The metal melts at 1173 °C.

Americium was discovered in 1944 by the American scientists Glenn T. Seaborg, Ralph A. James, Leon O. Morgan, and Albert Ghiorso when they bombarded plutonium with neutrons. It was named for its place of discovery, the United States of America. Americium is the only radioactive element known to be *superconductive* (see **Superconductivity**). It becomes superconductive when cooled to −272.36 °C. Richard L. Hahn

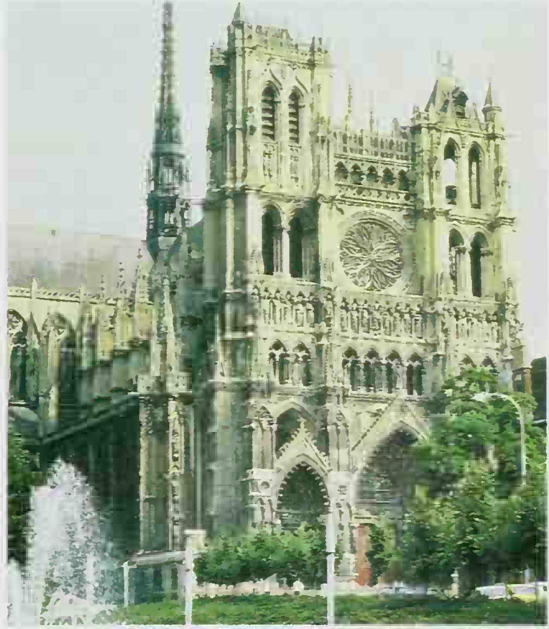
Amerigo Vespucci. See **Vespucci, Amerigo.**

Ames, Adelbert, Jr. (1880-1955), was an American scientist known for his research in optics and visual perception. His views on visual perception are known as the *transactional approach*.

Ames believed that a person's perception of the world confirms what the individual expects to see. Such expectations, according to Ames, result from past experiences—both conscious and subconscious. In one of the visual illusions that Ames designed to study this problem, a familiar object such as a playing card is increased in size while an observer views it. The observer would not say the card was increasing in size because the person would not expect it to do so. Instead, the person would conclude the card was moving closer.

Ames was born in Lowell, Massachusetts. He earned an LL.B. at Harvard University. Robert G. Weyant



Amethyst, *AM uh thihst,* is a gemstone of a purple or bluish-violet color. It is used to make rings, necklaces, and brooches. The amethyst is a variety of quartz. The color of the stone is believed to be caused by impurities such as iron and manganese. Amethysts have been mined in Brazil, Uruguay, Siberia, India, Sri Lanka, Madagascar, Mexico, and Canada. The amethyst is the birthstone for February. The *Oriental amethyst* is a purple variety of the mineral corundum. See also **Birthstone; Gem** (picture). Frederick H. Pough

Amherst, *AM uhrst,* **Lord Jeffery** (1717-1797), a British general, helped Britain win Canada from France. He captured Louisbourg, a French fort in present-day Nova Scotia, in 1758 during the Seven Years' War (known as

the French and Indian War in the United States). Amherst was made commander in chief of the British Army in North America after that victory. In 1759, he captured Crown Point and Fort Ticonderoga, both in present-day New York. In 1760, he directed an advance on Montreal, and the city surrendered.

Amherst was then responsible for administering Canada until his return to England in 1763. He was made a baron in 1776 and commander in chief of the British Army in 1778. He was born on Jan. 29, 1717, in Riverhead, near Tonbridge, England. Phillip Buckner

Amiens, *AM ee uhnz,* or in French *ah MYAN* (pop. 139,210; met. area. pop.: 160,815), is a city in northern France. The city lies along the Somme River (see **France** [political map]). The old section of Amiens has numerous buildings that date from the Middle Ages. This section is dominated by one of the world's largest and most famous Gothic cathedrals, which was built during the 1200's and 1300's. Much of the modern section of the city was built after World War II (1939-1945).

Haesler Art Publishers Art Resource

The cathedral in Amiens is a magnificent Gothic structure. It was built during the 1200's and 1300's. Much of the old section of Amiens dates from the Middle Ages.

Amiens serves as the capital of the Somme *department* (administrative district) and the Picardy region. It is also the region's center of commerce, communications, and education. The city's chief industries include food processing, metalworking, and the manufacture of agricultural machinery, textiles, and tires. The University of Picardy is in the city.

Julius Caesar had headquarters at the site of what is now Amiens in 54 B.C., during the Gallic War. The city grew during the Middle Ages, when it became a center of the textile trade. It was badly damaged in World War I (1914-1918) and World War II. Mark Kesselman

See also **Architecture** (picture: Gothic cathedrals).

Amin Dada, *ah MEEN DAH dah,* **Idi,** *EE dee* (1925?-), was the ruler of Uganda from 1971 to 1979. Amin, an army officer, came to power after leading the army in overthrowing Uganda's civilian government. His rule ended when Ugandans who opposed his policies and troops from neighboring Tanzania overthrew his government. Amin then fled the country.

Amin was a controversial leader. In 1972, he forced an estimated 40,000 to 50,000 Asians living in Uganda to leave the country. He said that he did so to put control of the nation's economy in the hands of Ugandans. Many thousands of Ugandans who opposed Amin's policies were killed, at Amin's order or by order of his supporters. Amin also called for the "extinction of Israel," praised Adolf Hitler for murdering Jews, and denounced the leaders of many nations.

Amin was born in northern Uganda. Amin enlisted in the army in 1944. He was appointed to the rank of deputy commander of the armed forces in 1964. From 1951 to 1960, Amin was the heavyweight boxing champion of Uganda. Robert I. Rotberg

Amino acid, *uh MEE noh,* is the name for the type of organic acids that make up all the proteins in living things. Scientists call amino acids the *building blocks of proteins.* All amino acids contain carbon, hydrogen, oxygen, and nitrogen. Some amino acids contain sulfur.

Green plants and some microorganisms can make all the amino acids they need. But human beings and higher animals cannot make all of the 20 amino acids their bodies need to build tissues. Humans must get at least nine amino acids from their food. Protein foods, such as eggs, meat, milk products, and some vegetables, provide amino acids. The body breaks down these foods into amino acids. It then links the amino acids to form new proteins.

The body can make many different kinds of proteins. A single protein may consist of several hundred amino acid units linked together by chemical bonds. Also, the order of the amino acids may vary, producing different proteins. These different amino acid sequences determine the functions of the proteins.

Some simple proteins may be made up of only four different kinds of amino acids. Most of the more complex proteins contain about 20 amino acids. All amino acids contain one or more groups of one nitrogen and two hydrogen atoms called *amino,* or NH_2, groups. Amino acids are made up of amino groups and certain organic acids. Kermit L. Carraway

See also **Protein; Cell** (The work of a cell); **Hormone** (How hormones work).

Amis, *AY mihs,* **Kingsley** (1922-1995), was an English novelist best known for his witty, satirical stories about British society. His most famous work is his first novel, *Lucky Jim* (1954). In it, Jim Dixon, a young university instructor, is disgusted by the falseness of his colleagues and their work. Amis's other novels include *That Uncertain Feeling* (1955), *Take a Girl Like You* (1960), *One Fat Englishman* (1964), *The Green Man* (1970), *Jake's Thing* (1979), *The Old Devils* (1986), *Difficulties with Girls* (1989), and *The Folks That Live on the Hill* (1990).

Kingsley William Amis was born on April 16, 1922, in London. In the 1950's, he became identified with the *Angry Young Men,* a group of writers who ridiculed middle-class society. Later, he began writing detective and

spy fiction under the name Robert Markham. Amis was also a noted poet. His *Collected Poems: 1944-1979* was published in 1979. *Memoirs* (1991) is a book of autobiographical essays. Amis was knighted by Queen Elizabeth II in 1990. Martin Amis, his son, is a noted English novelist. Michael Seidel

Amish, *AM ihsh* or *AH mihsh,* belong to a Protestant group that originated in Switzerland but is now centered in the United States and Canada. They are also called *Old Order Amish.* The Amish teach separation from the world. Members are forbidden to go to war, swear oaths, or hold public offices. Their doctrine requires farming and personal simplicity as a way of life. Men wear dark clothes and wide-brimmed hats; women wear plain long dresses and bonnets. Strict adherence to Amish ways prohibits the use of electricity, television, computers, and telephones in the home. Amish limit education to the age of 15. Those who break with the Old Order usually join the Mennonites (see **Mennonites**).

Richard Reinhold

Amish worshipers meet in their homes for services. These community members have driven to a service in carriages.

The Amish were named for Jacob Ammann, who led them in breaking away from the Swiss Mennonites in 1693 because of disagreements over church discipline. The Amish were stricter and *shunned* (avoided completely) excommunicated members. They first came to North America from 1717 to 1732, settling in Berks County, Pennsylvania. Today, they live in farm communities in 21 states and in Ontario. Their largest communities are found in Ohio, Pennsylvania, Indiana, Iowa, and Illinois. The Amish are part of the group called *Pennsylvania Dutch* (see **Pennsylvania Dutch**). There is no longer a separate Amish group in Europe. Charles H. Lippy

See also **Indiana** (Places to visit).

Wagner, Katherine. *Life in an Amish Community.* Lucent Bks., 2001.

Amistad Rebellion was a revolt in 1839 by black slaves against Spaniards who had bought them. The rebellion took place on a ship called *La Amistad.* Joseph Cinque, a member of the Mende people of what is now Sierra Leone, led the uprising. The slaves were later tried in courts in the United States for their rebellion and were found not guilty. This legal decision was a landmark because blacks had few rights at the time.

The slaves who became the Amistad rebels were captured in western Africa. Early in 1839, Spanish slave traders brought them to Cuba illegally on a Portuguese ship. In Havana, two Spaniards, Pedro Montez and José Ruiz, bought Cinque and 52 other captives from the traders. Montez and Ruiz intended to resell the 53 slaves in the Cuban town of Puerto Principe (now Camagüey). They set sail in the Caribbean Sea on the schooner *La Amistad.* They hired a ship captain and two crewmen. The captain brought a cook and a cabin boy with him.

The slaves were chained to a wall below the deck of the ship. One night, Cinque saw an opportunity to escape. He used a nail to break his wrist chains and iron collar. He helped other slaves get free and they, in turn, helped others. The slaves attacked the crew and took control of the ship. They killed the captain and his cook. The two crewmen jumped ship and escaped. Montez, Ruiz, and the cabin boy were captured by the slaves. Two slaves died during the rebellion.

The rebels did not know how to sail the ship. Cinque ordered Montez and Ruiz to sail it to Africa. During the day, the Spaniards sailed slowly eastward, the direction of Africa. At night, they secretly changed to a northwest course and moved rapidly. The ship ended up at Long Island, New York. Eight more rebels had died by then.

When *La Amistad* reached New York, Montez and Ruiz reported the killings. The rebels were arrested and taken to Connecticut, where they were put on trial.

United States district and circuit courts ruled that the rebels had been free people who were illegally enslaved and thus were justified in rebelling. The case went to the U.S. Supreme Court in 1841. John Quincy Adams, who had been president of the United States from 1825 to 1829, defended the rebels in the Supreme Court. He based his defense on the right of every person to be free. The court ruled in favor of the rebels. Cinque and most of the other remaining Amistad rebels returned to Africa in January 1842. Nudie Eugene Williams

Amman, *AHM mahn* (pop. 969,598), is the capital and largest city of Jordan. It lies 25 miles (40 kilometers) northeast of the Dead Sea (see **Jordan** [map]).

Most of Amman's buildings stand on several hills. The main streets run between the hills. Amman has many government buildings, churches, and *mosques* (Muslim houses of worship). The city lies on old trade routes and still is a major trading center. Its factories produce more than half of Jordan's manufactured goods.

About 1000 B.C., Amman, then called Rabbath-Ammon, was the capital of the Ammonites. The Bible describes how the Israelites, led by David and Joab, captured it. Greeks, Arab Muslims, and Turks later controlled the city. In 1921, Amman became the capital of the new state of Transjordan. Transjordan changed its name to Jordan in 1949. Bernard Reich

See also **Jordan** (picture).

Ammonia, *uh MOHN yuh* or *uh MOH nee uh* (chemical formula NH_3), is a colorless alkaline gas made up of one part nitrogen and three parts hydrogen. It is lighter

than air and has a sharp, stinging odor. Ammonia can be inhaled safely if it is greatly diluted in air, but concentrated ammonia gas can cause suffocation and death. Ammonia does not burn in air, but it burns in oxygen with a weak yellow flame.

Properties of ammonia. Ammonia is highly soluble in water and forms a solution known as *ammonium hydroxide* (ammonia water). Ammonia is not very reactive when dry, but it reacts with many chemicals when dissolved in water. Ammonium hydroxide neutralizes acids and forms the corresponding ammonium salts. For example, hydrochloric acid (HCl) added to ammonium hydroxide (NH_4OH) produces a solution of ammonium chloride (NH_4Cl). When combined with some metals, ammonium hydroxide forms complex compounds called *ammines*. For example, the addition of ammonium hydroxide to a pale blue solution of cupric sulfate ($CuSO_4$) produces a deep blue solution of cupric ammine sulfate [$Cu(NH_3)_4SO_4$].

Ammonia gas changes to a liquid at −33.35° C. Liquid ammonia boils at the same temperature. It freezes to a clear solid at −77.7 °C. In going from a liquid back to a gas, ammonia absorbs a large amount of heat from its surroundings. Upon evaporation, one gram of ammonia absorbs 327 calories of heat. For this reason, ammonia is widely used in refrigeration equipment.

Preparing ammonia. In the laboratory, ammonia is prepared by heating an ammonium salt with sodium hydroxide.

Commercially, ammonia is made by the Haber process, which combines free nitrogen and hydrogen gases, both of which can be obtained easily and cheaply (see **Haber process**). One volume of nitrogen is mixed with three volumes of hydrogen under high pressure and temperature in the presence of an iron catalyst (see **Catalysis**). Ammonia is also obtained as a by-product in the production of coal and coke gas.

Uses. Ammonia is widely used as a fertilizer. Ammonium nitrate and other ammonium salts help to increase crop production because they have a high percentage of nitrogen. In some farming areas, anhydrous ammonia is now applied directly to the fields from large tanks that contain the compressed gas.

Large quantities of ammonia are oxidized to make nitric acid, which is needed to make such explosives as TNT (trinitrotoluene), nitroglycerin, and ammonium nitrate. The textile industry uses ammonia in the production of synthetic fibers such as nylon and cuprammonium rayon. Ammonia is also used in dyeing and scouring cotton, wool, and other fibers. Ammonia water sometimes serves as a cleaning fluid and can be used to restore fabrics that have been stained by acids. Ammonia is also vital in the manufacture of many chemicals, plastics, vitamins, and drugs. David C. Armbruster

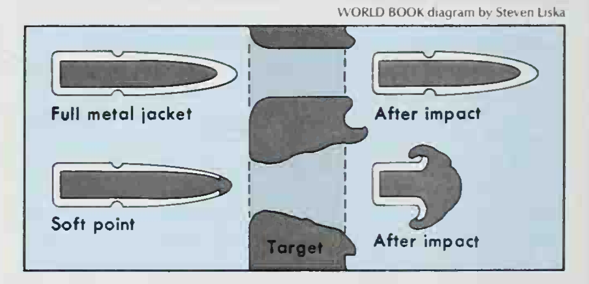
Ammons, A. R. (1926-2001), was an American poet whose verse explores natural processes, from the cosmic to the microscopic. Trained in science, Ammons brought to his poetry a subtle understanding of how organisms and events interact in nature to produce endless complexity. In one poem, "Cascadilla Falls," he contemplated a single stone while trying to imagine all the forces that affect it: gravity, the spinning of the earth and its orbit around the sun, and the movement of the solar system and galaxy.

The form and language of Ammons's poems often reflect the complexity he saw in nature. Some of his poems adopt a loose, wandering format with lines and phrases scattered across the page in patterns that suggest the uneven beauty of a wild landscape. Others unroll in regular groups of lines that resemble the rapid flowing of a stream. In their complex sentence structure and surprising shifts of vocabulary, his poems remind readers of the intricacy and variety of nature.

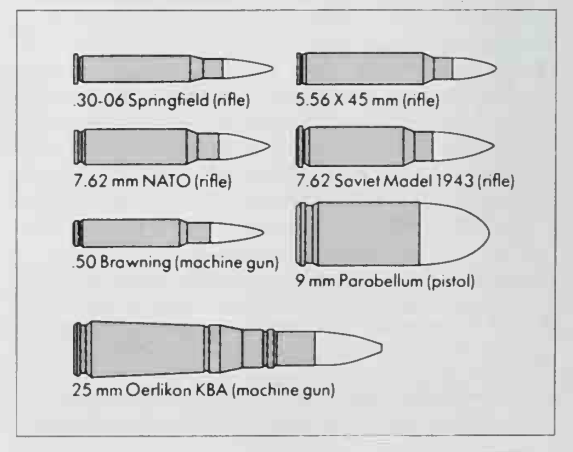


Archie Randolph Ammons was born in Whiteville, North Carolina. His *Selected Poems* were published in 1969, 1977, and 1986. Roger Gilbert

Ammunition is any object fired or launched from a gun or some other weapon. Such objects, also called *projectiles*, include cartridges, shells, and rockets. Weapons that fire projectiles include handguns, cannons, and rocket launchers. Guided missiles and torpedos are also examples of ammunition, but this article does not discuss them. For information on these two

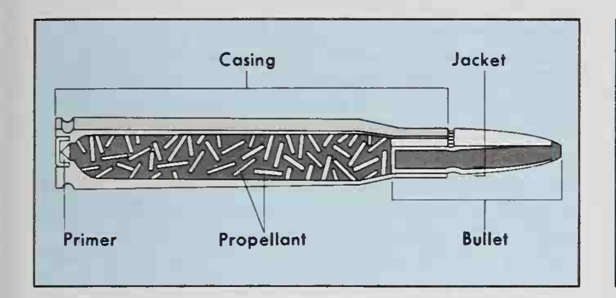
Kinds of bullets

Bullets consist of a metal core that is either fully or partly covered by a metal jacket. Bullets with a full metal jacket keep their shape when they strike a target. However, partly jacketed bullets, called *soft point bullets*, expand on impact, *shown here*.

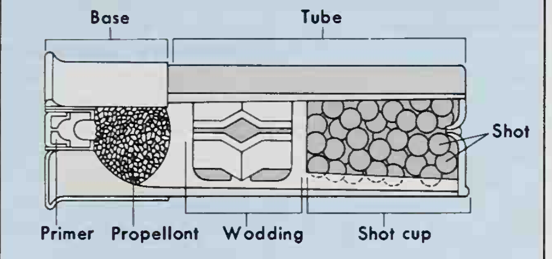


WORLD BOOK diagram by Steven Liska

Common calibers of cartridges



Caliber (bullet diameter) is given in decimal fractions of an inch or in millimeters (mm). For example, the diameter of a .30-06 Springfield cartridge, *shown here*, is $\frac{30}{100}$ inch. This is the same diameter as that of the 7.62 mm Soviet Model 1943. The illustrations are not drawn to the same scale.



WORLD BOOK illustrations by Bensen Studios

Kinds of small-arms ammunition The various small-arms cartridges differ in the type of projectile they contain. Most cartridges include a bullet, *left*. But shotgun cartridges contain a number of metal pellets called *shot, right*.

WORLD BOOK diagrams by Steven Liska

kinds of ammunition, see the **Guided missile** and **Torpedo** articles.

Most kinds of ammunition contain a *propellant,* which is an explosive or a fuel that provides the force to send the projectile to its target. Nearly all ammunition also has a *primer,* a small amount of an explosive that *detonates* (explodes) and ignites the propellant. Some types of ammunition contain an additional explosive that shatters the projectile when it reaches the target, thus increasing the damage.

Ammunition can be classified into three types, according to its effects: (1) *penetrators,* (2) *high explosives,* and (3) *carrier projectiles.* Penetrators pierce targets using a single bullet. High explosives burst before hitting their target, fragmenting into thousands of penetrating pieces or becoming a high-speed jet of molten metal. Carrier projectiles break open near the target to deliver leaflets, radar-deceiving materials, or *submunitions* (small ammunition).

Ammunition can also be categorized by the kind of weapon from which it is fired. Categorized this way, the main types of ammunition are (1) small-arms, (2) artillery, and (3) armored-vehicle ammunition.

Small-arms ammunition

Small arms include light weapons such as pistols, rifles, and shotguns. Most kinds of small arms fire penetrators called cartridges. A single cartridge is known as a *round.*

Cartridges are called *fixed ammunition* because they are manufactured as completely assembled units. Nearly all types of cartridges have a propellant, a primer, and a casing. However, cartridges differ in the type of projectile they contain. Most cartridges contain a bullet. Cartridges fired by shotguns hold metal pellets called *shot.*

The bullet is the projectile part of a cartridge. Most bullets have a steel or lead core covered by a jacket of hard metal. Some types of bullets expand when they strike their target and thus cause severe damage. International law forbids the military use of such bullets. Military forces use bullets that have a jacket of *gilding metal,* an alloy of copper and zinc that prevents expansion. Cartridges used in weapons other than shotguns are measured by *caliber* (the diameter of the bullet). Manufacturers and users of ammunition in the United States have traditionally specified caliber in decimal fractions of an inch. For example, a .30-caliber cartridge has a diameter of $\frac{30}{100}$ inch (7.6 millimeters). However, it is becoming customary to use millimeters instead. The U.S. armed forces specify caliber in millimeters. Small-arms cartridges are less than 20 millimeters or .78 caliber.

The propellant drives the bullet from the gun and propels it to the target. Propellants used in guns are called *low explosives.* Low explosives *deflagrate* (burn rapidly). This accelerates the bullet through the gun's barrel. All small-arms ammunition has a propellant of smokeless powder, which consists of nitrocellulose or a mixture of nitrocellulose and nitroglycerin. This powder is also used in firing projectiles from cannons.

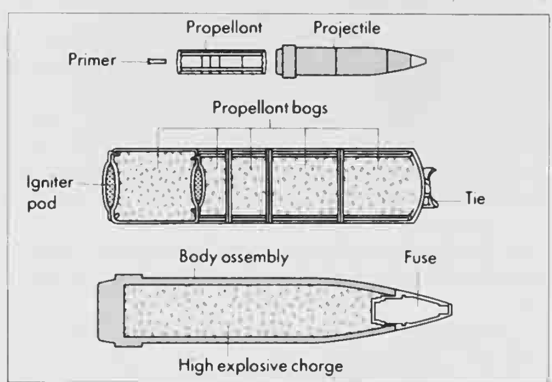
The primer explodes when struck by the *firing pin,* a hammerlike device inside a gun. Lead styphnate is a common primer material.

The casing holds the propellant and the primer and also grips the base of the projectile. It remains in the gun or falls out when the bullet is fired. Most casings are made of aluminum alloys or brass. Some cartridges have no casing. The propellant in caseless cartridges is molded to the base of the bullet. *Cased, telescoped cartridges* hide the bullet inside the propellant.

Shotgun cartridges consist of a plastic or paper tube with a brass or steel case at one end. They contain lead or steel shot instead of bullets.

Riot control ammunition is used by law enforcement officials to subdue rioters without causing serious injury. Most of this ammunition consists of hard rubber bullets. Another type is made of soft rubber rings that look like doughnuts and may contain tear gas. These rings cause less damage than do the rubber bullets.

Artillery ammunition



Artillery includes rocket launchers and such mounted guns as howitzers, mortars, antiaircraft guns, and naval guns. Most types of field and naval artillery ammunition are called *shells.* A single shell, like a single cartridge, is known as a round. Field artillery projectiles range in size from 50 to 240 millimeters and can weigh over 200 pounds (90 kilograms). Most artillery shells taper to the rear, a shape that gives them greater range. Some have streamlined *ogives* (nose shields). Others, known as *base-burner shells,* have a small amount of propellant burning in the tail during flight. This reduces *drag* (air resistance).

Some shells are high explosives, which detonate on impact and damage or destroy the target. Detonating the shell's explosive filler shatters the shell into thousands of fragments. High explosives include TNT; RDX, also known as cyclonite or hexogen; composition B, a

Artillery ammunition

Separate loading ammunition consists of separate sections for the projectile, the primer, and a propelling charge, *upper figure.* The propelling charge and projectile are shown in detail in the two lower figures.

WORLD BOOK illustrations by Bensen Studios

mixture of RDX and TNT; PETN; and pentolite, a combination of PETN and TNT. Other shells contain mines or small shells that can be expelled at intervals over a specified area or during a certain period of time.

Still other shells are filled with a nonexplosive substance, such as a chemical that is poisonous or that produces smoke or fire. *Illuminating,* or *star, shells* light up the battlefield or seascape. A shell with a *chaff warhead* expels strips of aluminum, which produce images on a radar screen similar to those caused by aircraft. Such images confuse radar operators and thus help protect aircraft from enemy attack.

There are five main types of artillery shells: (1) fixed ammunition; (2) semifixed ammunition; (3) separate loading, or bag, ammunition; (4) separated ammunition; and (5) guided ammunition. The word *shell* often refers not only to the entire unit of ammunition but also to the actual projectile part of the unit.

Fixed ammunition fired by artillery consists of a projectile, a casing, a primer, and a propellant. Like small-arms cartridges, fixed artillery ammunition shells are manufactured as complete units.

Semifixed ammunition resembles fixed ammunition. However, the projectile fits loosely into the casing so that the sections can be separated. Thus, the amount of propellant in the casing can be increased or decreased, depending on how far the shell is from the target.

Separate loading ammunition, also called *bag ammunition,* consists of separate sections for the projectile, the primer, and the propellant. The propellant is packed into bags that are placed behind the projectile. The number of bags used depends on the distance the shell must travel. This type of ammunition is used to fire the heaviest artillery shells over great distances.

Separated ammunition consists of two sections. One section is the projectile. The other includes the primer, the casing, and a fixed amount of propellant.

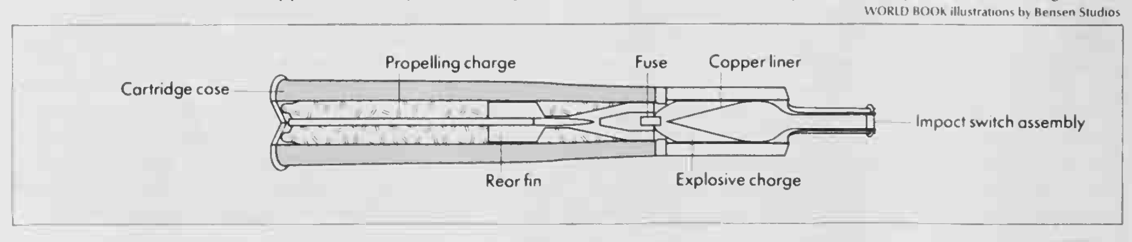
Guided ammunition can correct its flight in the air after being fired. It often uses pop-out tail fins to steer itself. Most guided ammunition finds its target by tracking a laser spot on the target. This spot is usually produced by a *forward observer,* a person or object forward of the line of fire. Some shells known as *smart shells* have small radars and computers in them. These shells can search for and find such targets as armored vehicles or trucks without help.

How shells explode. A shell explodes by means of a process called the *explosive train.* This process consists of a series of explosions that detonate the shell after the projectile has been fired.

The explosive train begins with the explosion of the *fuse* (triggering device). The fuse may explode the instant the shell hits the target, or it may detonate a few seconds earlier or later. Some armor-piercing shells have a delayed fuse, which enables the projectile to penetrate before exploding. Most fuses operate mechanically or electronically. Mechanical fuses are activated by the movement of the shell during launch from the weapon, and the rotation of the shell as it travels through the air. Electronic *proximity fuses* are activated by devices inside the shell that use radar waves to determine when the projectile is near the target.

In most shells, the fuse ignites the primer and thus sets off the first charge in the explosive train. Each successive charge in the process is more powerful than the previous one. The amount of force generated by the explosion of the charges increases until enough power has been created to detonate the main charge.

Armored-vehicle ammunition



Armored-vehicle ammunition consists of projectiles fired by guns mounted on tanks and other armored vehicles. They have diameters from 20 to 125 millimeters.

A common armored-vehicle penetrator is a projectile with a nose cap of tungsten or another heavy metal. The cap helps the projectile penetrate opposing vehicles. A high explosive projectile is a *hollow-charge warhead.* This warhead is hollow in the front and has an explosive charge in the back. Its explosion converts a copper cone in the warhead to a molten, high-speed jet. The jet penetrates the target. Another armored vehicle projectile is a long dart made of tungsten or *depleted uranium* (ura-

nium with most of its radioactivity removed). The dart travels on a device called a *sabot,* which breaks away after the dart leaves the gun's barrel.

History

Stones, which people hurled from slings and other small weapons, were the first form of ammunition. The ancient Romans flung stones from huge siege weapons, such as the ballista and catapult. Arrows fired by longbows were effective ammunition against armored knights during the European Middle Ages (A.D. 400's to 1500's). By the mid-1300's, gunpowder was used to fire stones from cannons. By the 1400's, iron and lead balls were also used as artillery ammunition.

During the 1400's, people began to use handheld weapons that fired lead balls by the use of a trigger. By the 1500's, the Dutch had developed powder-filled metal bombs that were fired from mortars. Cartridges became common in Europe in the early 1600's. During the 1800's, people began using paper fuses and shotguns that fired lead shot enclosed in paper shells. Smokeless powder also was invented in the 1800's.

During World War I (1914-1918), high explosive shells, *incendiary* (fire-producing) bullets and shells, and chemical shells became common. In 1953, the United States Army fired the first shell with a nuclear charge. In the 1960's and 1970's, developments included the production of shells and cartridges made of plastics and lighter, stronger metals. Increasingly powerful propellants and more sophisticated guidance systems also came into use. In the 1980's, weapons experts improved ammunition by increasing its range. Multiple-rocket launchers took the place of many big guns. Weapons experts continue to work to create projectiles that can disable several targets, such as an entire tank column, at once.

Amnesia, *am NEE zhuh,* is a partial or, in rare cases, a complete loss of memory. Everyone forgets minor daily incidents as time goes by, but a person with amnesia has large gaps in memory. People who suffer from amnesia lose the ability to recall past or recent experiences (see **Memory** [Uncommon memory conditions]). They may even leave their homes, wander for a while, and start a new life somewhere else. This wandering while experiencing amnesia is called *psychogenic fugue.* Amnesia may be caused by emotional shock, disease, or physical injury. In emotional shock, amnesia is usually restricted to experiences closely related to the cause of the shock. Doctors treat amnesia of emotional origin by hypnosis or with such drugs as sodium amytal or thiopental. Diseases and injuries may cause changes in the brain, making recall impossible. Nancy C. Andreasen

Amnesty, *AM nuh stee,* is forgiveness by a government for crimes against it. Amnesty restores wrongdoers to the legal status they had before committing the crimes. The term comes from the Greek word *amnestia,* which means *a forgetting.*

Throughout history, governments have granted amnesty to restore unity after a war or an internal uprising. One of the earliest recorded amnesties took place in 403 B.C., when the people of the ancient Greek city of Athens overthrew their rulers, the Thirty Tyrants, and established a democracy. The new leader, Thrasybulus, declared amnesty for all citizens except the Thirty Tyrants and a few other officials.

The Constitution of the United States gives the president authority "to grant reprieves and pardons for offenses against the United States." Those words establish the president's power to declare amnesty because there is no actual difference between an amnesty and a pardon. However, a pardon is granted to an individual, and an amnesty is granted to a group of people. In addition, most pardons are issued after the offender has been convicted. Most amnesties are granted before trial. Congress also can grant amnesties.

During the late 1700's and early 1800's, several presidents used their amnesty powers. In 1795, for example, President George Washington granted amnesty to Pennsylvania residents who had participated in an uprising called the Whiskey Rebellion (see **Whiskey Rebellion**). In 1807, President Thomas Jefferson offered amnesty to all Army deserters who returned to their posts within four months. President James Madison extended similar amnesty before and during the War of 1812.

The Civil War brought a number of amnesty declarations. In 1863, President Abraham Lincoln granted amnesty to Confederates who swore to support the Union. Thousands of soldiers accepted his offer. Lincoln and his successor, Andrew Johnson, issued several more conditional amnesties. In 1898, Congress extended unconditional amnesty to all former Confederates.

Since the early 1900's, most amnesties have involved people who opposed the nation's involvement in a war. In 1917 and 1918, many Americans criticized the U.S. role in World War I. Nearly 2,000 persons were imprisoned for their protests. During the 1920's, Presidents Warren G. Harding and Calvin Coolidge pardoned many individuals on a case-by-case basis. In 1933, President Franklin D. Roosevelt issued an amnesty that restored the voting rights of more than 1,500 of the protesters. They had lost these rights by being convicted of certain crimes in connection with their protests.

After World War II ended in 1945, President Harry S. Truman established a panel to study the individual cases of men who had evaded the draft or had deserted. The board suggested pardons for 1,523 individuals. But it refused to recommend amnesty for men who, according to the board, had "set themselves up as wiser and more competent than society to determine their duty."

In the 1960's and early 1970's, many Americans opposed the Vietnam War. The government estimated that about 93,000 U.S. servicemen deserted or were discharged for going *AWOL* (absent without leave), and about 13,000 men evaded the draft. Many fled to foreign countries or went into hiding in the United States. After U.S. involvement in the war ended in 1973, many people demanded amnesty for the entire group. The demand increased in 1974 after President Gerald R. Ford pardoned former President Richard M. Nixon for all federal crimes he may have committed as chief executive. Ford offered conditional amnesty to deserters and draft evaders who agreed to take public-service jobs. Only about 22,000 men applied for amnesty. In 1977, President

Jimmy Carter granted a pardon to nearly everyone who violated draft laws between 1964 and 1973. The pardon covered all except employees of the draft system and those who used violence in breaking draft laws.

In 1987, the U.S. government began an amnesty program for aliens who had entered the country illegally before Jan. 1, 1982, and had resided in the United States since then. The program was part of the Immigration Reform and Control Act of 1986. Stanley I. Kutler

Amnesty International, *AM nuh stee,* is an independent, worldwide human-rights organization. It works to free people imprisoned "for their beliefs, color, ethnic origin, sex, religion, or language, provided they have neither used nor advocated violence." The organization also works for fair and speedy trials for political prisoners and for an end to torture and executions. It received the Nobel Peace Prize in 1977.

Amnesty International has about 700,000 members in over 150 nations and includes about 4,000 volunteer groups. Each local group "adopts" prisoners in foreign countries. It works for their release by pressuring government officials and arousing public opinion. The organization also sends observers to political trials and on missions to investigate human rights abuses. Amnesty International was founded in 1961. Its headquarters are in London. Critically reviewed by Amnesty International USA

Amniocentesis, *AM nee oh sehn TEE sihs,* is a medical procedure performed during pregnancy to help determine the health and maturity of an unborn baby. It involves the withdrawal and study of a small amount of the *amniotic fluid* that surrounds the fetus in the mother's uterus. With this procedure, physicians can accurately diagnose more than 150 serious disorders that may affect the fetus. Such disorders include Down syndrome and Tay-Sachs disease. Amniocentesis involves little risk to either the mother or the fetus.

Amniocentesis is usually performed either late in the fourth month of pregnancy or during the last three months. In the fourth month, its purpose is to detect genetic disorders. The physician can then immediately treat the fetus for certain diseases or plan to treat other disorders right after birth. Some parents choose to end the pregnancy if amniocentesis reveals an incurable disorder. Amniocentesis is performed during the last three months of pregnancy primarily to determine whether the fetus has reached a normal stage of development.

A physician performs amniocentesis with the aid of *ultrasound* (high frequency sound waves). The ultrasonic waves produce an image of the fetus on a special screen. The physician monitors the position of the fetus while inserting a long hollow needle through the mother's abdominal wall and into the uterus. The physician then withdraws a small amount of amniotic fluid, which contains cells shed by the fetus. These cells are allowed to grow under controlled laboratory conditions for a few weeks and are then examined. Other procedures used by physicians to determine the health of a fetus are *chorionic villus sampling* and *alpha-fetoprotein analysis* (see **Genetic counseling**). Henry L. Nadler

Amoeba. See Ameba.

Amon, *AH muhn,* became the most important god in ancient Egyptian mythology. He was worshiped mainly in the city of Thebes, and was specially honored by the kings of Thebes. Amon's temples at Karnak and Luxor were the wealthiest in the country. Amon gained his greatest importance during the period of the New Kingdom (1554-1070 B.C.), when Thebes was the capital of Egypt. The Egyptians eventually identified Amon with the sun god Re to create a new deity called Amon-Re, who was known as King of the Gods.

Amon first appeared in Egyptian mythology about 2100 B.C. He may have been introduced to Thebes from Hermopolis, a city north of Thebes. At Thebes, Amon's wife was the goddess Mut. Their child was Khons, a moon god. The three became known as the *Theban triad.* Amon was usually portrayed in human form, wearing a double plumed crown. He sometimes appeared as a goose or a ram. R. F. G. Sweet

Amos, Book of, is a book of the Old Testament, or Hebrew Bible, named for an Israelite prophet. Amos was the first prophet to have his sayings collected into a single work. He expressed for the first time in the prophetic literature the idea that there is one God for all humanity, for both Israel and the other nations.

Amos was a native of the southern kingdom of Judah and was active at the shrine of Bethel in the northern kingdom of Israel. Amos prophesied from about 750 to 740 B.C. Most of his statements are announcements of judgment or prophecies of punishment. He stated that God was about to intervene in history to punish Israel for its sins. Amos criticized the excesses in the outward expression of religion. He declared that the Israelites' religion had no worth without demonstrating righteousness and social justice. He pointed out that Israel should suffer more for its sins than the surrounding nations because the Hebrews knew the true God. Eric M. Meyers

Amoy. See **Xiamen**.

Ampere, *AM pihr,* is the unit used to measure the rate of flow of an electric current. It is one of seven base units in the metric system. There is an electric current of 1 ampere when 1 unit of electric charge flows past a cross section of an electric circuit in 1 second. The unit of electric charge is called a *coulomb* (see **Coulomb**). Thus, 1 ampere equals 1 coulomb per second. Physicists also define amperes in terms of the magnetic force produced by electric currents in parallel wires.

A 100-watt light bulb requires about 1 ampere of current at 100 volts. Calculators and computers use currents so tiny they are measured in *microamperes* (millionths of amperes). Large industrial equipment uses currents measured in *kiloamperes* (thousands of amperes). The ampere was named for the French physicist André Marie Ampère. He was the first person to show that currents flowing through parallel wires cause magnetic forces between the wires (see **Ampère, André Marie**). Raymond D. Findlay

See also **Ohm's law**.

Ampère, *ahn PAIR* or *AM peer,* **André Marie,** *ahn DRAY mah REE* (1775-1836), a French mathematician

and physicist, discovered the laws of electromagnetism in the 1820's. He showed that parallel electric currents attract each other if they move in the same direction, and repel if their directions are opposite. His mathematical theory describing these phenomena provided the foundation for the development of electrodynamics. He found that an electric current flowing through a coiled wire acts like a magnet. This led to the invention of the galvanometer, an instrument for detecting and measuring electric currents. Ampère used the galvanometer to show that an electric current completes a circuit through the battery which produces the current.

Born in Lyon, Ampère showed early promise as a mathematician. He taught at the École Polytechnique in Paris. His classic work, *Mathematical Theory of Electrodynamic Phenomena,* was published in 1827.

Richard G. Olson

Amphetamine, *am FEHT uh meen,* is one of several drugs that increase physical and mental activity, prevent sleep, and decrease appetite. Many people become psychologically dependent on amphetamines, and some scientists believe these drugs can also cause addiction. The United States and many other countries prohibit the use of amphetamines unless prescribed by a physician. But many people take them illegally for energy or pleasure.

Amphetamines include such drugs as Benzedrine, Dexedrine, and methamphetamine. They are sometimes called "bennies," "pep pills," "uppers," or "wakeups." Methamphetamine is also called "speed" (see **Methamphetamine**).

Medical uses. Doctors prescribe amphetamines for three purposes. The drugs decrease appetite, but they lose this effect in a few weeks. They also control *narcolepsy,* an illness that causes sudden, uncontrollable attacks of sleep. In addition, amphetamines calm children with *hyperkinesis,* a brain disorder that causes constant activity and inability to concentrate. Physicians do not know why amphetamines have the opposite effect on hyperkinetic children than on other patients.

Amphetamine abuse. Some people occasionally take amphetamines to stay awake or to increase their confidence and energy for such activities as study or athletics. But amphetamines do little to speed learning, and they may slow it down. In athletics, the drugs increase alertness and may quicken reflex actions. But amphetamines have an unpredictable effect on strength, and they may cause poor judgment.

A person who uses amphetamines regularly must take increasingly large doses to get the same effects. In time, the person may feel dizzy, irritable, nervous, or shaky.

Some people take large, repeated doses of amphetamines. Most of these users inject the drugs, but some sniff or swallow them. Such doses produce a sense of joyous excitement. The user becomes extremely active and talkative and feels able to do anything.

When the effects of amphetamines wear off, users sleep for hours. After awakening, they feel hungry, sluggish, and depressed. To feel better, they may start to take amphetamines again. Some users feel so depressed that they attempt suicide.

Persons who take large, repeated doses of amphetamines may become overly alert, tense, and suspicious. These users may believe that others want to hurt them, and they may try to injure these "enemies." Such beliefs and actions resemble those of some persons with the mental illness called *paranoia.* Amphetamine users may also *hallucinate* (see, hear, or feel things that are not present). If a person stops using the drugs, the paranoid feelings and hallucinations will probably disappear.

Continued use of large amounts of amphetamines may cause physical collapse and even death. Constant supervision, and group discussions with former amphetamine users, have helped many users break their drug habit. Donald J. Wolk

Amphibian. See **Airplane** (Seaplanes).

Amphibian, *am FIHB ee uhn,* is an animal with scaleless skin that—with a few exceptions—lives part of its life in water and part on land. There are about 4,000 kinds of amphibians, and they make up one of the classes of *vertebrates* (animals with backbones). Amphibians include frogs, toads, salamanders, and caecilians.

Most amphibians hatch from eggs laid in water or moist ground, and begin life as water-dwelling *larvae* (young). Through a gradual process called *metamorphosis,* the larvae change into adults. The adults look very different from the larvae. Some adults continue to live in water, but most spend their lives on land. Almost all return to water to find mates and produce young.

Amphibians are generally smaller than such other vertebrates as fish, birds, and mammals. Most amphibians are no more than 6 inches (15 centimeters) long and weigh less than 2 ounces (60 grams). The smallest frog

WORLD BOOK illustration by Richard Lewington

Amphibians are divided into three main groups: (1) caecilians, (2) salamanders, and (3) frogs and toads. These drawings show representatives from each of the three groups.

in the world can sit on a person's thumbnail. The largest amphibian is the Japanese giant salamander. Adults can be more than 5 feet ($1\frac{1}{2}$ meters) long.

Amphibians are cold-blooded—that is, their body temperature stays about the same as the temperature of their surroundings. Those that live in regions with harsh winters hibernate during the cold weather. Many of those that live in warm, dry climates *estivate*—that is, become inactive during summer.

Amphibians live on every continent except Antarctica. They generally live in moist habitats near ponds, lakes, or streams. Certain tropical tree frogs never leave the trees. They lay their eggs in rain water that collects at the base of leaves. Some amphibians live in dry regions. They survive for weeks or months in moist places underground, waiting for rain to create puddles. After a rainfall, they gather at the puddles to mate and lay their eggs. The eggs hatch and the larvae develop quickly, before the puddles dry up.

Most amphibians eat insects. In some areas of the world, amphibians are quite numerous, and they play an important role in maintaining the balance of nature. Amphibians aid people by eating insects and insect larvae that destroy crops and carry disease. In some places, people use amphibians as food.

Kinds of amphibians

Zoologists divide amphibians into three groups: (1) frogs and toads; (2) salamanders; and (3) caecilians.

Frogs and toads have four legs and no tail. Their hind legs are very long and are used for jumping. Frogs generally have longer legs than toads. There are about 3,800 species of frogs and toads. Most of them live in tropical climates. But two species occur as far north as the Arctic Circle, and others are found as far south as Tierra del Fuego, at the tip of South America.

Salamanders have long tails and four—or in a few species, two—short, weak legs. There are about 360 species of salamanders. Most live in *temperate zones*—that is, in areas of the world having seasonal changes in temperature. Salamanders are also common in warm, humid areas of Central America and South America.

Caecilians have no legs and look like large earthworms. There are about 160 species of caecilians, which are found only in tropical regions. Most caecilians live in underground burrows, but some are aquatic.

The bodies of amphibians

Skin of amphibians has no external scales, hair, or feathers. Most amphibians have smooth skin, but some toads have thick, leathery skin. The outer layer of skin, called the *epidermis,* protects the animal's deeper tissues. Adult amphibians shed the outermost portion of the epidermis several times a year. The inner layer of skin, called the *dermis,* contains many nerves and blood vessels. It also has many glands, which open onto the skin surface. Many of them produce *mucus,* a thick, slimy substance that moistens and protects the skin. Other glands produce poisons that can hurt or kill an enemy.

Many frogs and salamanders have brightly colored skin. The color results from *pigments* (coloring matter) found in special cells that lie just below the epidermis. Movement of the pigments in the cells allows some species to change color rapidly. For example, some change color when the temperature goes up or down.

Breathing. Most land-dwelling adult amphibians breathe with lungs. Water-dwelling adults and larvae breathe by means of gills, as do fish. Some adults have both lungs and gills. In addition, all amphibians take in oxygen through the skin and through the lining of the mouth and throat. Some small salamanders have no lungs and breathe only through the skin and mouth.

Digestive system of amphibians includes the mouth, *esophagus* (tube to the stomach), stomach, and intestines. Food is mixed and partially *digested* (broken down) in the stomach, but most digestion takes place in the small intestine. The walls of the stomach and small intestine contain numerous glands that secrete digestive juices, which break food down into substances that can be absorbed and used by the animal's body. In addition, two large glands—the liver and pancreas—pour digestive juices into the small intestine. The digested food is absorbed from the small intestine, and the remaining wastes travel down the large intestine to the *cloaca,* a chamber that opens to the outside of the body. Waste products, eggs, and sperm (male sex cells) all pass out of the body through the cloaca.

Sense organs. Most frogs, toads, and salamanders have good eyesight, which helps them catch insects. Caecilians' eyes are either very small or completely absent. Caecilians have little use for eyes in their underground burrows. Water-dwelling amphibians also have a *lateral line system,* which is a set of sensitive organs along the sides of the body. It allows an animal to sense movement in the surrounding water.

Frogs and toads can hear a wider range of sounds than salamanders and caecilians. Frogs and toads have well-developed voices. Their calls are important in mating. Caecilians and most salamanders have no voices.

Most amphibians smell and taste by means of the *Jacobson's organ,* a pair of tiny cavities in the roof of the mouth. The tissues that line these cavities respond to chemical changes in the mouth or nose.

Ways of life

Reproduction. Amphibians generally mate during a rainy period. They gather at night into large groups to find partners. Among frogs and toads, *fertilization*—that is, the joining of egg and sperm—takes place outside the female's body. Among salamanders and caecilians, fertilization occurs inside the female's body, before the eggs are laid. In most amphibians, the females lay many eggs at one time. The eggs generally develop and hatch in water or another moist place.

Amphibian eggs do not have shells but are enclosed in a jellylike substance. The adults usually leave the eggs unguarded. However, some frogs and toads carry the eggs until they hatch, and caecilians wrap their bodies around the eggs. The eggs hatch into larvae with gills, a flattened tail, and tiny limbs or no limbs at all. Frog and toad larvae are known as *tadpoles* or *polliwogs.* Metamorphosis into adults takes from two weeks to several months. The larvae slowly lose their gills and develop lungs. Among tadpoles, the hind legs develop before the front legs do. The eyes, digestive system, and other organs must also undergo changes to prepare the amphibian for life on land.

Interesting facts about amphibians

WORLD BOOK illustrations by James Teason

Some amphibians change color and body form during the mating season. A male smooth newt is shown in its nonbreeding form, *above left,* and its breeding form, *above right.*

Metamorphosis, which involves striking changes in body structure, occurs during the growth of most amphibians. The metamorphosis of a southern leopard frog is shown above.

The largest amphibian, the Japanese giant salamander, *above,* is 5 feet (1 ½ meters) long.

Unlike most amphibians, a female caecilian, *above,* guards her eggs.

A prehistoric labyrinthodont, *above,* was one of the first amphibians.

Food and enemies. Most amphibian larvae eat algae and plant material, but salamander larvae feed on small water animals. Adult amphibians prey on insects and many other kinds of small animals. Bullfrogs and other large amphibians may eat snakes, small mammals, and birds. One group of South American frogs feeds mainly on other frogs. Most amphibians use their tongues to capture prey.

Adult amphibians have many enemies, including snakes, birds, and mammals. Numerous kinds of fish and small water animals prey on amphibian larvae. Amphibians use many methods to protect themselves. Some amphibians are hard to see because they are the same color as their surroundings. Tree frogs are often green, and ground-dwelling salamanders may be dull gray or brown. Salamanders and caecilians avoid their enemies simply by staying out of sight. Caecilians are so well hidden in their burrows that even scientists know little about them. Poisons from the skin glands of some frogs and salamanders irritate the mouths of attackers.

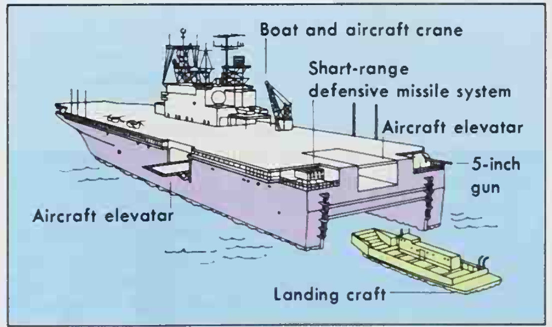
The history of amphibians

According to *paleontologists* (scientists who study prehistoric life), the oldest fossils of amphibians date back to the end of the Devonian Period—about 360 million years ago. Amphibians are thought to have been the first group of vertebrates to emerge from the water and live on land. Most scientists believe the amphibians *evolved* (developed slowly) from the *lobe-finned fish.* Lobe-finned fish had lungs and enlarged fins supported

by bones and muscles. They could use their fins as legs to come out of the water for brief periods. These fins probably developed into amphibian legs. Amphibians were the most important vertebrates on land during the Carboniferous Period—from 360 million to 286 million years ago. There were many more kinds of amphibians then than there are now.

The groups to which modern amphibians belong did not appear until the Mesozoic Era—from 248 million to 65 million years ago. By then, most of the other amphibians had died out. Scientists do not know all the reasons why amphibians became less numerous. The world's climate was becoming drier, and many of the ponds and lakes needed by amphibians were disappearing. Also, reptiles, which first appeared during the Pennsylvanian Period, were becoming more important. Reptiles are not so dependent on water because they have hard-shelled eggs that will not dry out on land. Reptiles probably ate the same foods as many of the early amphibians and probably preyed on amphibians themselves.

Today, there are fewer species of amphibians than of any other class of vertebrates. Human activities pose the biggest threat to amphibians. Amphibians are successful in moist, humid areas of the world, but such habitats are continually reduced by the construction of roads, towns, and farms. J. Whitfield Gibbons



See **Frog**, **Salamander**, and **Toad** with their *Related article* lists. See also **Heart** (Amphibians and reptiles).

Amphibious ship, *am FIHB ee uhs,* is a warship that lands troops, weapons, and vehicles on beaches during amphibious assaults. Some amphibious ships unload troops and equipment directly onto a beach. Others transfer troops and cargo using helicopters and small amphibious landing craft.

Amphibious ships generally have only short-range guns and missiles for defense against aircraft. However, some amphibious ships also have rocket launchers for bombing shorelines. Amphibious ships measure up to 820 feet (245 meters) long and travel at speeds of about 20 knots (nautical miles per hour). Most are equipped to handle helicopter take-offs and landings. Both the United States and Russia have many amphibious ships. The United States Navy has various kinds of amphibious ships. They include assault, cargo, command, dock landing, and tank landing vessels.

Large amphibious assault ships carry up to 30 helicopters. They also have a garage for trucks and armored vehicles. Some assault ships have a *docking well* that can be flooded, enabling landing craft to float out and carry troops ashore. Amphibious cargo ships carry provisions, landing craft, and heavy equipment. Amphibious command ships serve as communications centers that coordinate air, surface, and shore operations.

Dock landing ships are combination ships and dry docks. They transport landing craft and dry-dock them for repairs. Tank landing ships unload troops, cargo, and vehicles directly onto a beach through large doors in the bow. Norman Polmar

WORLD BOOK diagram by George Suyeoka

Amphibious ships, such as the U.S.S. *Tarawa,* land troops, weapons, and vehicles for amphibious attacks. The *Tarawa,* as seen from the stern, is shown in this diagram.

Amphibious warfare, *am FIHB ee uhs,* is the conduct of military operations by naval, air, and land forces for the purpose of seizing a beach or coastal area. Amphibious operations are generally considered the most complex form of warfare. In the Pacific Ocean region during World War II (1939-1945), a common objective of United States amphibious operations was to seize islands on which to build advance air and naval bases for operations against Japan.

Steps in amphibious operations. Officers of the various forces taking part in an amphibious operation first decide where the landing will take place. They plan the number and kinds of ships, planes, and troops that will take part. Even the loading of the ships is carefully worked out so that the troops will have the equipment they need in the order that they need to use it.

The first step in an amphibious landing is to gain complete mastery of the skies over the area to be seized. Planes from aircraft carriers or land bases destroy enemy defenses. Next, warships bombard the landing beach with naval guns and rockets to prevent defenders from shooting at the approaching landing craft and helicopters.

Amphibious ships then arrive with troops, weapons, vehicles, and other cargo. Some unload the troops and equipment directly onto the beach. Others transfer the troops and equipment using small amphibious landing craft and helicopters. Once a *beachhead* (foothold) has been established, amphibious ships and cargo ships send more troops and equipment ashore.

History of amphibious warfare. The ancient Greeks and Romans carried out early forms of amphibious landings. In 1066, the Normans undertook a successful amphibious landing when they invaded England (see **Norman Conquest**).

Amphibious operations played a major role in World War II. The Japanese carried out amphibious assaults on the Philippines, Malaya, and the East Indies. American forces counterattacked with amphibious landings in the Central Pacific. Beginning at Guadalcanal in the Solomon Islands, they worked their way toward Japan by landing on numerous Pacific islands. Allied troops also made amphibious invasions of North Africa and Italy. The Allied landing at Normandy in northern France on June 6, 1944—known as D-Day—was the largest amphibious invasion in history. German and Soviet forces also made amphibious landings during the war.

During the Korean War (1950-1953), U.S. marines made a difficult but highly successful landing at the Korean port of Inchon on the Yellow Sea. In 1982, British forces made a major amphibious landing in the Falkland Islands after Argentine troops invaded and occupied the

islands. U.S. troops undertook an amphibious invasion of the Caribbean island of Grenada in 1983 after Communists took control of Grenada's government.

After World War II, American and British forces developed techniques for moving troops by helicopter from ship to shore. Today, air cushion vehicles (ACV's) are also used. ACV's can move troops and equipment at high speeds from amphibious ships to the beach. These craft travel on a cushion of air and can move over land or water (see **Air cushion vehicle**). The U.S. Navy has large numbers of ACV's. Norman Polmar

Amphibole, *AM fuh bohl,* is any one of a large group of relatively hard minerals found in many igneous and metamorphic rocks (see **Rock**). Many amphiboles are shaped like blades. Many are black, brown, or green, though they can be almost any color.

An amphibole called nephrite is the chief source of jade, which is widely used for fine carvings and jewelry. Amphibole asbestos is used in cement pipe and in filters that are resistant to harsh chemicals.

The general chemical formula for amphiboles is $A_{0\text{-}1}X_2Y_5Z_8O_{22}(OH)_2$, in which *A* can be potassium or sodium; *X* can be calcium, magnesium, manganese, or sodium; *Y* can be aluminum, iron, magnesium, manganese, or titanium; and *Z* can be aluminum or silicon. Amphibole crystals form in the monoclinic or the orthorhombic system (see **Crystal** [Classifying crystals]). They have pyramid-shaped units of silicon and oxygen that are linked in double chains. David L. Bish

See also **Asbestos**; **Jade**; **Silicate**.

Amphioxus, *AM fee AHK suhs,* also called *lancelet, LANS liht,* is a small sea animal that lives in shallow water. It is a link between vertebrates and invertebrates. It has no distinct brain, but it has a nerve cord running along its back that is similar to the spinal cord of animals with backbones. Instead of the hard, jointed backbone of the vertebrates, the amphioxus has an organ called the *notochord.* This is a fairly stiff rod of cartilage, found along the back just under the nerve cord. This primitive form of backbone makes the amphioxus more like a vertebrate than an invertebrate. L. Muscatine

S. Stammers, Science Photo Library

The amphioxus is a slender, fishlike sea animal that lives in shallow water. The amphioxus is also known as the lancelet.

Scientific classification. Amphioxus is in the family Branchiostomidae. A typical lancelet is *Branchiostoma costa.*

Amphisbaenian, *AM fihs BAY nee uhn,* also known as *worm lizard,* is any of a group of wormlike, burrowing reptiles related to lizards and snakes. More than 100 amphisbaenian species live in warm regions around the world, largely in Africa, South America, and southern North America.

Adult amphisbaenians range from about 3 to 30 inches (8 to 76 centimeters) long. All species have long bodies with tiny eyes. An amphisbaenian's thick, bony skull helps it dig tunnels through the soil. Its loose skin enables it to travel underground using *rectilinear motion.* In this motion, the reptile moves part of its skin forward and anchors it against the tunnel walls. It then uses muscles to move the rest of its body forward with the skin. Most amphisbaenians have no limbs. However, three Mexican species have well developed front limbs with toes and claws for digging.

© Jany Sauvanet, Photo Researchers

An amphisbaenian has a long, wormlike body and tiny eyes. It spends most of its life underground in tunnels that it digs through the soil. Amphisbaenians inhabit many warm regions.

Amphisbaenians usually lay eggs, but a few kinds give birth to live young. All species are effective predators, using good hearing and strong jaws to find and capture prey. The reptiles feed primarily on such small animals as worms and insects. D. Bruce Means

Scientific classification. Amphisbaenians belong to the order Squamata in the class Reptilia. They make up the suborder Amphisbaenia.

Ampicillin, *AM puh SIHL ihn,* is a drug used to treat infections caused by certain bacteria. It is an *antibiotic* (drug produced by microbes). It belongs to the penicillin group of drugs and is a *semisynthetic penicillin.*

Ampicillin can kill some bacteria that are not effectively killed by *penicillin G,* one of the most widely used forms of penicillin. For example, ampicillin is used against *Salmonella* bacteria, which cause a form of food poisoning. The drug is also effective in treating severe ear and sinus infections, meningitis in children, and urinary and respiratory tract infections.

Some people who take ampicillin suffer side effects. In most cases, the side effects are minor, such as rashes. But some people who take the drug by mouth develop diarrhea. In such cases, physicians prescribe a semisynthetic penicillin called *amoxicillin,* which produces fewer side effects involving the stomach and intestines.

Ampicillin was introduced in 1961. Since then, its effectiveness has decreased as some of the bacteria that were once killed by the drug have developed a resistance to it. Eugene M. Johnson, Jr.

See also **Penicillin**.

Amputation, *AM pyuh TAY shuhn,* is the process of cutting off a limb, part of a limb, or another part of the body. Amputation may be necessary as a result of severe injury, infection, tumor, or other diseases.

Before surgery, the patient is given an anesthetic. The

body part to receive the incision is cleaned, disinfected, and protected with a drape. The surgeon uses a *tourniquet* (tight cloth wrapped around the limb) to stop the flow of blood through the large vessels of the limb (see **Tourniquet**). The soft tissues are cut apart in a way they can be used to cover the end of the bone.

Before cutting through the bone, the surgeon severs and ties the blood vessels to prevent bleeding. The surgeon then saws through the bone. After this, the tourniquet is released. In most amputations done under war conditions, the wound cannot be closed immediately because of danger of infection. In such cases, healing takes many weeks. In most cases resulting from injury in civilian life, the wound can be sewed up right after the amputation. The most common dangers are infection, hemorrhage, and shock. James A. Hill

See also **Artificial limb**.

Amritsar, *uhm RIHT suhr* (pop. 975,695), is a manufacturing center in Punjab, a state in northern India (see **India** [political map]). Amritsar was founded in 1577. It is the holy city of Sikhism, an Indian religion. The city grew up around the famous Golden Temple, the main center of Sikh devotion. The temple stands in a *tank* (pool) of constantly changing fresh water. The city was named for the tank, which was called *Amritsar*—meaning *the tank of nectar or immortality*. Sikhs and Hindus live in Amritsar. Factories include steel mills, cement plants, spinning mills, carpet and silk-weaving firms, and factories that manufacture electrical and chemical products. See also **Sikhism** (picture). P. P. Karan

Amsterdam (pop. 724,096; met. area pop. 1,100,120) is the capital and largest city of the Netherlands. It lies at the junction of the Amstel River and the IJ, an arm of a large lake called the IJsselmeer. For location, see **Netherlands** (political map). The city's name means *dam of the Amstel* and refers to a dam built there in the 1200's. Amsterdam is the national capital, but the seat of government is in The Hague, 34 miles (55 kilometers) away.

The city lies on marshy land slightly below sea level. Most of its buildings stand on large wooden or concrete *piles* (posts) driven into the soggy ground. More than 100 canals crisscross the city and help drain the land. The canals and attractive buildings help make Amsterdam one of Europe's most charming cities.

The old section of Amsterdam lies at the heart of the city. This section is a jumble of narrow streets, many of which are closed to automobile traffic. Some of its buildings date from the Middle Ages. The Royal Palace, built in the mid-1600's, overlooks Dam Square at the center of the old section. Next to the palace stands the Nieuwe Kerk (New Church), where the nation's monarchs are inaugurated. The church was built in the 1400's. The city's stock exchange, founded in 1612, is nearby.

The IJ and the port area are just north of the old section. Three canals—the Herengracht, the Keizersgracht, and the Prinsengracht—border the old section on the east, south, and west. Impressive mansions, built during the 1600's by the city's merchants, line the canals. Many of the mansions are now banks or office buildings. Beyond the canals are large neighborhoods and suburbs built during the 1800's and 1900's.

Amsterdam's major cultural attractions include the Rijksmuseum, Amsterdam's principal art museum; the Stedelijk Museum, a municipal museum of modern art; and the Van Gogh Museum, which features many works by the famous Dutch painter Vincent van Gogh. Amsterdam also has a municipal theater, two universities, and the world-famous Royal Concertgebouw Orchestra.

Economy. Amsterdam's economy is based on financial services, manufacturing, tourism, and foreign trade. The city is the headquarters of the Netherlands Central Bank, the nation's major commercial banks, and many insurance and investment companies. Amsterdam's stock exchange is part of Euronext, an exchange serving all of Europe. Its industries include aircraft manufacturing, electronics, food processing, publishing, ship repairing, and production of chemicals and steel. Few other cities attract more foreign visitors than Amsterdam. Canals link the city to the North Sea and to the Rhine River, Europe's chief waterway. Schiphol Airport lies south of Amsterdam.

History. Amsterdam was founded about 1200 as a fishing village. A dam was built there during the 1200's. The village then became the point for cargo transfers between seagoing ships on the IJ and boats on the Amstel River. By the 1400's, Amsterdam had developed into a prosperous center of European trade.

The city began to grow rapidly in the 1580's. During

Photri

Handsome mansions line the Keizersgracht, *shown here,* one of the main canals of Amsterdam. The city's merchants built the mansions during the 1600's. Glass-topped boats take visitors on tours of the canals.

that period, and for about the next 100 years, thousands of political and religious refugees fled to Amsterdam to escape persecution. They included Jews from Portugal and Protestant merchants from Antwerp and other cities in Flanders. They helped establish a variety of industries and trade links. The city's trade spread to Africa, the Americas, the East Indies, and elsewhere. Amsterdam was Europe's greatest trading center during the 1600's, and the city's cultural life also flourished.

During the 1700's, Amsterdam developed into a great financial center. Its bankers lent money throughout Europe, especially to foreign governments. France took control of the Netherlands in 1795 and made Amsterdam the capital in 1808. But the Dutch restored their government in The Hague after they regained independence in 1813. Amsterdam's economy was ruined during the period of French rule, but the opening of the North Sea Canal in 1876 helped revive it.

Amsterdam's people suffered greatly during World War II (1939-1945). The city was occupied by German troops, and its Jewish community was almost wiped out in Nazi concentration camps. Jews had made up about 10 percent of Amsterdam's population before the war. The city also suffered a severe famine during the winter of 1944, and thousands starved.

Amsterdam had a housing shortage for many years after World War II. To relieve overcrowding, several carefully planned residential areas were built on the outskirts of the city. One apartment complex, constructed in the 1970's, houses 100,000 people. A subway connects the complex to the old section of the city. Jan de Vries

Amtrak is a semipublic corporation that operates intercity passenger trains in the United States. It was created by Congress in 1970 and took over the operation of intercity trains in 1971. It is partly financed by the U.S. government. All members of Amtrak's board of directors are nominated by the president or by the Department of Transportation.

When Amtrak was created, *subsidies* (grants) from Congress covered about 50 percent of its operating costs. But financial support has decreased as the purchase of new equipment has made Amtrak more efficient. Amtrak owns and maintains the tracks on the busy "Northeast Corridor" between Boston, New York City, and Washington, D.C. Elsewhere, it pays freight railroads for the use of their tracks. Amtrak hires its own train crews, operates its own stations, and buys its own locomotives and cars. Amtrak also establishes routes and schedules, and handles ticket sales. It receives income from ticket sales and from carrying mail and express parcels. Richard Saunders, Jr.

See also **Railroad** (map: Railroad passenger routes).

Amulet, *AM yuh liht,* is a charm that supposedly has magic power. It may be worn around the neck. Some people believe that amulets protect them from evil, sickness, and witchcraft. Amulets may be made of any material, but many are made of stone. Others are small cloth bags filled with a supposedly powerful object. A tooth or a piece of horn or wood can also serve as an amulet. Some amulets have a symbolic shape, such as a crescent. Alan Dundes

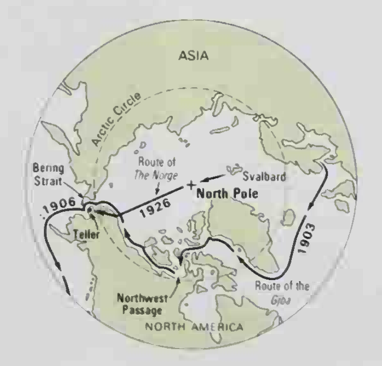
Amundsen, *AH muhn suhn* or *AH muhnd suhn,* **Roald,** *ROH ahl* (1872-1928), a Norwegian explorer, led the first expedition to reach the South Pole. Amundsen and four companions discovered the pole on Dec. 14, 1911. They beat a British expedition led by Robert F. Scott by five weeks. Amundsen is also noted for his many Arctic explorations.

Bettmann Archive



Roald Amundsen

The race to the South Pole. Amundsen had originally planned on discovering the North Pole. He organized an Arctic expedition and was about to leave when he heard that Commander Robert E. Peary, an American explorer, had just reached the pole (see **Peary, Robert E.**). Amundsen changed his plans and decided to lead an expedition to the South Pole instead.

Amundsen left Norway secretly in June 1910 aboard the ship *Fram.* At about the same time, Scott, unaware of Amundsen's expedition, also was on his way to the Antarctic. While stopping in Melbourne, Australia, in October 1910, Scott received a message from Amundsen informing him that Amundsen was proceeding to Antarctica. The race to the South Pole was on.

Amundsen and his crew arrived at the eastern edge of the Ross Ice Shelf in January 1911. They spent an Antarctic winter there, making short trips inland to set

Roald Amundsen explored in the Arctic and Antarctic regions. During a voyage from 1903 to 1906, he sailed his ship, the *Gjöa,* along the water route called the Northwest Passage. In 1911, Amundsen crossed the Ross Ice Shelf of Antarctica and discovered the South Pole. In 1926, he flew over the North Pole in a dirigible, the *Norge.*

WORLD BOOK maps

up stores of food and fuel. On Oct. 19, 1911, after spring had arrived, Amundsen and his men set off for the pole in four sleds pulled by 52 dogs. Near the journey's end, when they were no longer needed to pull the sleds, the weaker dogs were killed. They were fed to the surviving animals and to the men.

Scott's expedition met with disaster. Instead of using dogs all the way, Scott relied mainly on ponies to pull the sledges. But the ponies became exhausted and had to be shot. Without ponies, the men had to pull the sledges, carrying the supplies. The men also had to fight severe cold and fierce winds, and they lacked the proper clothes for such conditions. See **Scott, Robert F.**

Amundsen had a smooth journey by comparison. The route he had chosen was shorter than Scott's and covered flatter terrain. The dogs withstood the hard work and cold well, and the weather was clear.

On Dec. 14, 1911, Amundsen and his companions calculated that they had reached the South Pole. They began their return journey three days later, leaving behind them a tent and a Norwegian flag. Five weeks later, Scott and his men finally reached the pole, only to discover that Amundsen had been there first. Weary and disappointed, they began their return. But injuries, fatigue, and continued bad weather slowed them down. The entire party soon died of cold and hunger.

Other achievements. Roald Engelbregt Gravning Amundsen was born in Borge, near Oslo. He studied medicine for two years before going to sea in 1897 aboard the *Belgica.* During this voyage, Amundsen's efforts helped to combat scurvy among the crew. In 1898, the *Belgica,* with Amundsen aboard, became the first ship to winter in Antarctic waters. In 1906, Amundsen completed the first voyage from the Atlantic to the Pacific through the Arctic waters of Canada. During this voyage through the Northwest Passage, Amundsen determined the precise position of the north magnetic pole. From 1918 to 1920, he sailed the Northeast Passage. He traveled from Norway through the Arctic Ocean to the Bering Sea. Amundsen was the first person to sail both the Northwest and Northeast passages.

In 1926, Amundsen made history by flying over the North Pole in an airship called the *Norge.* The aircraft was piloted by Umberto Nobile, an Italian explorer. In June 1928, Amundsen and his crew vanished in the Arctic while searching for Nobile, who had disappeared in May. Nobile was eventually rescued. Barry M. Gough

Amur River, *uh MOOR,* is a huge river in eastern Siberia, formed by the joining of the Argun and Shilka rivers. The Amur-Argun river system is about 2,744 miles (4,416 kilometers) long (see **Russia** [terrain map]).

The Amur flows east along China's northern border and then turns north into the Khabarovsk Region of Russia. It empties into the northern Tatar Strait, a narrow band of water separating Sakhalin Island from the east coast of Siberia. The valleys of the Amur and its branches cover about 715,000 square miles (1,850,000 square kilometers). These branches include the Ussuri, Sungari, Zeya, and Bureya rivers. Large dams have been built on the Zeya and the Bureya. The Amur becomes wide in the Khabarovsk Region, and it often floods there during the summer monsoon season.

Large boats operate on the Amur for most of its length from April to November. The cities of Khabarovsk and Komsomolsk stand on the banks of the Amur. Railroads link both cities with the port of Vladivostok to the south. Craig ZumBrunnen

Amusement park is a permanent outdoor entertainment complex that typically offers games, rides, and shows. There are amusement parks in many countries, but most of the larger parks are in the United States.

Amusement parks developed in the United States in the late 1800's. One of the earliest types was the *trolley park.* Railways built these at the end of their lines to encourage the weekend use of trolleys. The World's Columbian Exposition, held in Chicago in 1893, stimulated the development of the amusement park. The first important park, and the model for all later parks, was opened in the late 1800's at Coney Island, a beach resort in the Brooklyn area of New York City.

Amusement parks flourished from about 1900 until World War II (1939-1945). Since then, their popularity has declined, and many parks have closed. In the United States, *theme parks* have replaced many amusement parks. They are organized around such themes as local historical events, pioneer life, and wildlife. They emphasize cleanliness, courtesy, and family entertainment. The first theme park, Disneyland, opened in 1955 in Anaheim, California. Its theme is the cartoon characters created by Walt Disney. Don B. Wilmeth

Amusements. See **Recreation.**

AMVETS is an organization of veterans who have served honorably in the United States military. It was founded in 1944 during World War II and chartered by Congress in 1947. Its major aims are to promote world peace, to preserve the American way of life, and to help veterans help themselves. AMVETS has about 150,000 members and about 1,400 local posts. Its headquarters are in Lanham, Maryland. Critically reviewed by AMVETS

Amyotrophic lateral sclerosis, *uh MY uh TRAHF ihk LAT uhr uhl sklih ROH sihs,* also called ALS, is a rare, incurable disease of the nervous system. It is also called *Lou Gehrig's disease,* after a baseball player who died from it. ALS gradually destroys the nerves that control the muscles. Weakness, paralysis, and eventually death result. Physicians advise patients to remain active as long as possible. No treatment can halt ALS.

ALS develops when certain nerve cells in the brain and spinal cord *degenerate* (break down) and die. These cells, called *motor neurons,* make the muscles work by sending them *impulses* (nerve messages). As the motor neurons degenerate, they lose the ability to transmit impulses. The muscles they control gradually stop working and then waste away. Physicians believe that there may be more than one cause of ALS. In 2000, scientists in California and France discovered traces of a virus, called

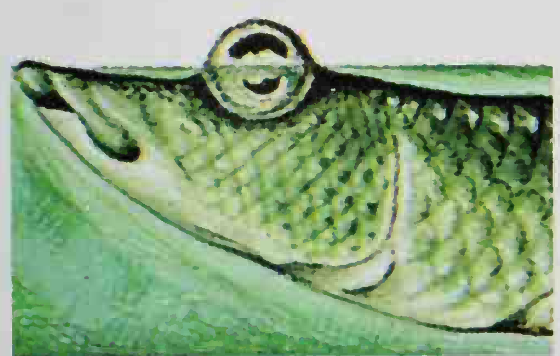
echovirus 7, in the spinal nerves of several patients who died of ALS. If a viral cause is confirmed, treatments for ALS might one day be possible.

Small twitches occur in ALS patients as the dying neurons send irregular impulses to the muscles. The arms and legs grow increasingly weak. Patients find it hard to walk and to do simple tasks with their hands. They lose weight and gradually become paralyzed as their muscles grow useless. Talking and swallowing may become hard. Death occurs when the muscles that control breathing stop working. In most cases, this happens within two to five years after the first symptoms appear.

ALS is painless and does not affect the mind. It afflicts slightly more men than women. Most patients develop the symptoms in their 50's. William J. Weiner

See also **Gehrig, Lou.**

Anabaptists were one form of what has been called the radical wing of the Reformation of the 1500's. The Anabaptists believed that the church was a gathering of people united by faith, repentance, obedience, and discipline. Therefore, baptism as an entrance to this community should be limited to believers old enough to choose membership. People called them *anabaptists* (rebaptizers) because they baptized adults who had been baptized in infancy. The Anabaptists condemned government involvement in religion, which eventually led to the idea of the separation of church and state.

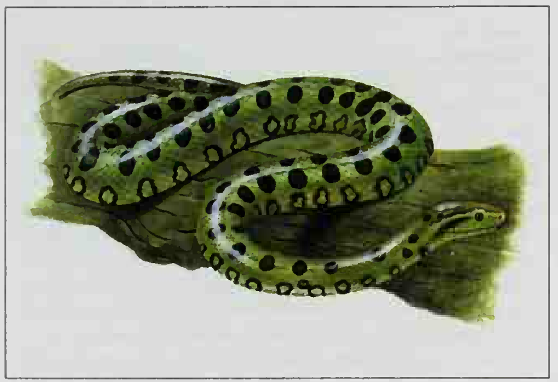


Many Anabaptists were persecuted in both Protestant and Roman Catholic countries. Their movement was concentrated in Switzerland, southern Germany, Austria, and the Netherlands. The Anabaptists' beliefs survive today in Mennonite and Hutterite religious communities (see **Mennonites; Hutterites**). Stanley K. Stowers

See also **Reformation** (Zwingli and the Anabaptists).

Anableps, *AN uh blehps,* also called *four-eyed fish,* is a small fish that lives in freshwater streams of tropical America. This fish swims at the top of the water with its eyes projecting partway into the air. The upper half of each eye can see threatening birds of prey in the air. The lower half, different in structure, can see underwater and enables the fish to find food. John E. McCosker

Scientific classification. The anableps belongs to the family Anablepidae. It is *Anableps anableps.*



See also **Fish** (Interesting facts about fish).

WORLD BOOK illustration by Harry McNaught

The anableps swims with its eyes projecting partway into the air. Both eyes are divided into two parts. The top part can see above water, while the bottom part can see underwater.

Anaconda, *AN uh KAHN duh,* is the name of two kinds of large snakes found in tropical South America. Anacondas are also called *water boas.* One kind may grow as long as 30 feet (9 meters) or more. But all adult anacondas are more than 15 feet (4.6 meters) long. No other South American snake approaches this length.

WORLD BOOK illustration by Richard Lewington, The Garden Studio

The anaconda is the largest snake in the Western Hemisphere. A typical anaconda has olive-green skin with black rings or spots. It lives in the tropical forests and rivers of South America.

Anacondas have olive-green skin, often with many black rings or spots. These snakes live near water, often swimming in rivers. Anacondas bear live young. Their main foods are birds and small mammals. They kill their prey by wrapping their coils tightly around them to keep them from breathing. Only the largest anacondas ever attack large mammals. Like most snakes, they defend themselves from enemies by retreating or, if cornered, by biting. Their bite is not poisonous, but their many teeth can inflict deep wounds. Albert F. Bennett

Scientific classification. Anacondas are members of the family Boidae. They are classified as *Eunectes murinas* and *E. notaeus.*

See also **Boa; Boa constrictor; Python.**

Anacreon, *uh NAK ree uhn* (572?-487 B.C.), a Greek lyric poet, made wine and love his main themes. Little of his work has survived. Most of the so-called *Anacreontics,* popular in the 1700's, are imitations. The tune of a drinking song about him, "To Anacreon in Heaven," was adopted for "The Star-Spangled Banner" (see **Star-Spangled Banner**). He is called "the Teian bard" because he was born in Teos, in Ionia. The emphasis on wit and pleasure in his poems is probably due to the taste and demands of his royal patrons. Cynthia W. Shelmerdine

Anaheim, *AN uh HYM* (pop. 328,014), is a residential and light-industrial city and tourist center in southern California. It lies 28 miles (45 kilometers) southeast of Los Angeles and 16 miles (26 kilometers) from the Pacific Ocean (see **California** [political map]). It is part of the Orange County metropolitan area, which has a population of 2,846,289. Anaheim's more than 1,000 industries include aircraft, automotive, electronics, engineering, and hardware plants. Disneyland, an amusement park that opened in 1955, is the largest employer. A second park, Disney's California Adventure, opened in 2001. The Anaheim Angels baseball team is in the American League. The Mighty Ducks play in the National Hockey League.

Anaheim was originally part of a Spanish land grant to the San Gabriel mission. The city was founded in 1857 as an agricultural community by a group of former Forty-Niners, mostly of German descent (see **Forty-Niners**). The name *Anaheim* means *home by the Santa Ana River.* Anaheim has a council-manager form of government.

James J. Rawls

Analgesic, *AN uhl JEE zihk,* is any drug that relieves pain without causing unconsciousness. People use various analgesics to eliminate or reduce many types of pain. Aspirin, a relatively mild analgesic, relieves headaches, muscle pains, and some discomforts of a cold. A doctor may prescribe more powerful analgesics, such as codeine, for the severe pain caused by back injuries, serious burns, and such illnesses as cancer. Analgesics relieve pain by acting on the nervous system or by blocking the formation of *prostaglandins,* hormonelike chemicals found throughout the body. However, scientists do not know exactly how analgesics work.

There are two kinds of analgesics, *narcotic* and *nonnarcotic.* Narcotic analgesics, also known as *opioid analgesics,* relieve severe pain but are addictive. Nonnarcotic analgesics relieve only fairly minor pain but are not addictive. The most commonly used nonnarcotic analgesics include *acetylsalicylic acid,* or aspirin; and acetaminophen, used by many people who cannot take aspirin without suffering side effects. Acetaminophen is sold under many trade names, the best known probably being Tylenol. Narcotic analgesics include codeine, morphine, and meperidine, a drug that is often referred to by the trade name Demerol.

The misuse of any analgesic can cause severe illness or death. Narcotic analgesics are especially dangerous because they are addictive. For this reason, narcotic analgesics can be legally obtained only with a prescription from a physician or dentist. N. E. Sladek

Acetaminophen	Drug	Morphine
Aspirin	Drug abuse	Narcotic
Codeine	Ibuprofen	

Analog computer is a device that solves problems by measuring a continuously varying quantity, such as weight, speed, or voltage. Many familiar devices, including speedometers and thermometers, work as analog computers. An analog computer replaces a calculation with a physical system that performs the calculation. For example, the rise and fall of mercury in a thermometer imitates a change in temperature.

Analog computers reached the peak of their popularity in the 1940's. During World War II (1939-1945), they were used to calculate the paths of bombs and bullets. The development of *digital computers* since that war limited the use of analog computers. A digital computer uses numerical digits to represent a quantity. Today, most computers are digital. See **Computer.**

An electronic analog computer represents numbers with electrical quantities, especially voltages, and solves problems by manipulating those quantities. Electronic analog computers are useful for representing quantities that change continuously. They are sometimes used to duplicate the behavior of machines and some natural systems. Analog computers may be programmed to solve a wide variety of equations that describe such systems.

Analog computers can be extremely fast. However, they are not as accurate as digital computers because they work with quantities that cannot be measured precisely. Digital computers count rather than measure, so their accuracy is limited only by the number of digits they can handle. A. K. Dewdney

Analogous structures. See **Homologous structures.**

Analytic geometry. See **Geometry.**

Anaphylactic shock, *an uh fu LAK tihk,* also called *anaphylaxis,* is a rare, life-threatening allergic reaction that affects the whole body. The reaction develops rapidly after two or more exposures to an *allergen* (substance that causes an allergy). The allergens that cause most anaphylactic reactions include bee and wasp venom, antibiotics, latex rubber, and such foods as eggs, nuts, and shellfish.

Symptoms of anaphylactic shock include skin rashes, wheezing, chest tightness, and nausea. The blood pressure drops, and the person may collapse. Without immediate medical attention, death may occur. Doctors treat anaphylactic shock with epinephrine or certain other drugs and oxygen to help restore normal blood pressure and breathing.

Usually, the speed of an anaphylactic reaction makes the allergen that caused the attack obvious. If there is any doubt, blood and skin tests can help people identify and avoid the allergen. People also should wear a medical bracelet identifying the allergen and carry an emergency epinephrine injection for use should another attack occur. Carol A. Hirshman

Anarchism, *AN uhr kihz uhm,* is a belief that every form of regulation or government is immoral, and that restraint of one person by another is an evil which must be destroyed. *Anarchism* comes from a Greek word meaning *without government.*

Anarchism dates back to ancient times. The legends of many countries tell of a "golden age" of freedom which preceded organized governments. Anarchism also appeared among early Christian groups.

Later anarchism proposed a social organization that was based on common ownership and free agreements, but its disciples differed among themselves in methods and forms. Pierre Joseph Proudhon of France, often called the father of anarchism, became the first to make anarchism a mass movement. Proudhon's *philosophical,* or *individualistic,* anarchism urged the willing cooperation of free individuals without any regulation or government.

Terroristic anarchism began under the leadership of Mikhail Bakunin (1814-1876) in Russia during the 1800's. Followers of this type of anarchism believed in the destruction of the government by violence and terror. They thought that land and other means of production should be owned in common. Many anarchists throughout the world resorted to revolution and assassination in the belief that terror would correct what they thought to be evil. They murdered heads of governments, including Czar Alexander II of Russia and President William McKinley of the United States. After the death of McKinley, the U.S. government passed a law barring anarchists from entering the country.

Anarchism under the leadership of Prince Peter Kropotkin of Russia, during the late 1800's, assumed a

more rigid communistic form. Kropotkin rejected the terroristic methods of Bakunin, but he also opposed the authoritative type of communism. Under his kind of anarchism, the state would be eliminated and society would be built on the *communes,* or *village communities,* which had existed in feudal Russian society. Each commune would be a self-sufficient group.

The strength of anarchism declined throughout the world in the 1900's. Anarchists played a part in the Spanish Civil War (1936-1939). Anarchism also influenced such radical groups as Students for a Democratic Society (SDS) in the United States in the 1960's, and the Baader-Meinhof gang in West Germany in the 1970's. Some groups in Europe practice terroristic anarchism.

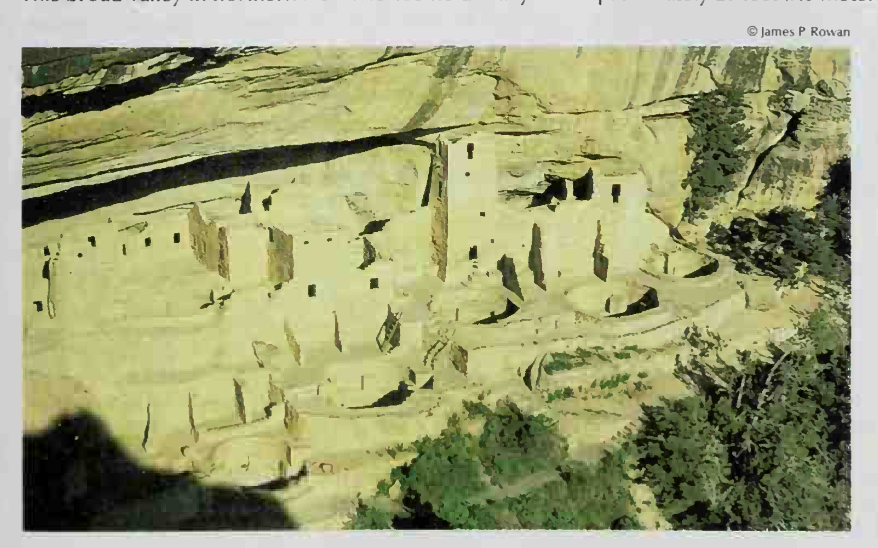
Anasazi, *AH nuh SAH zee,* sometimes called the *cliff dwellers* or *Ancestral Puebloans,* were the ancestors of the modern-day Pueblo Indians. The Anasazi culture centered in the southwestern United States, especially in what is now the Four Corners area, where Colorado, Utah, New Mexico, and Arizona meet. In that region, about A.D. 1100, the Anasazi built homes called *cliff dwellings* in canyon walls or under rocky overhangs.

History. The Anasazi culture developed from Basketmaker ancestors in the Southwest about A.D. 1. They lived in villages of *pit houses,* underground pits with roofs formed by a wooden framework covered with earth. They farmed and gathered food in the wild. Around 750, they began building *pueblos,* aboveground structures resembling modern apartment buildings. By this time, the Anasazi traded extensively with peoples in what are now Mexico and California.

The Anasazi built their first large pueblos about 900, in the area known today as Chaco Canyon, New Mexico. This broad valley in northern New Mexico held many large pueblos made of shaped stone. The pueblos were two or three stories high with many rooms. The largest, Pueblo Bonito, had about 800 rooms and may have housed as many as 1,200 people. The Anasazi in Chaco Canyon produced turquoise beads and figurines. The Anasazi of Chaco Canyon traded with peoples in what is now Mexico for such items as copper bells, shell trumpets, and macaws. The Chaco Canyon culture ended about 1150, perhaps due to drought, warfare, or disease.



Some of the Chaco Canyon peoples settled in the Four Corners area, the location of the famous cliff dwellings seen at Mesa Verde National Park in Colorado. These buildings consist of many levels of rooms built one above another. The largest cliff dwellings, constructed of sandstone, could house as many as 2,500 people.

The Anasazi abandoned the area about 1300. Scientists have developed several theories to explain why the sites were abandoned, including drought, invasion, plague, and resource depletion, but no theory has completely answered the question. Some people moved to northern New Mexico, while others settled on *mesas* (flat-topped hills) in eastern Arizona. There they built large multi-story surface pueblos and developed the traits of Puebloan culture seen today in the peoples known as Hopi and Zuni.

Way of life. The Anasazi built large permanent structures because their agricultural lifestyle allowed them to stay in one place for long periods. In valleys and on top of mesas, they grew corn, beans, squash, cotton, and tobacco. They raised turkeys, but they also hunted both deer and mountain sheep to add to their diet. Hunters and warriors launched stone-tipped spears using a device called an *atlatl (AHT laht uhl),* a stick with a spur at one end to hold the butt of the spear. Between 400 and 700, Anasazi hunters had begun to use the bow and arrow. Anasazi warfare may have included cannibalism.

During the winter, the Anasazi wore robes and blankets made from rabbit fur and turkey feathers. During the summer, both men and women wore skirts made from cotton and other materials. The men held social and religious ceremonies in *kivas,* underground pits approximately 25 feet (7.6 meters) in diameter. Colorful

A multilevel Anasazi home known as the Cliff Palace is the largest cliff dwelling in Mesa Verde National Park in southwestern Colorado. Some sections of the Cliff Palace are four stories high. The Anasazi began building cliff dwellings in about 1200.

symbolic paintings decorated the walls of the kivas.

The dry climate of the Southwest and the protection of the cliffs and canyons preserved many items made by the Anasazi. Archaeologists have found many artifacts that the Indians used in everyday life, including clothing and stone tools. Anasazi potters created fine ceramics, the earliest of which were black-on white style. Later, pottery featured black-and-red patterns painted on jars, bowls, and pitchers. As pottery techniques improved, these designs became more complex. By studying the patterns on fragments of pottery, archaeologists can determine the age of Anasazi ruins. Thomas R. Hester

Anatolia. See Asia Minor; Turkey.

Anatolian shepherd is a breed of large, rugged working dog. It stands about 30 inches (76 centimeters) tall at the shoulders and weighs from 80 to 150 pounds (36 to 68 kilograms). The breed has an outer coat that varies from short to medium long and a thick undercoat. Coat colors include *fawn* (light beige), white, *brindle* (black body with brown stripes), and *pinto* (white body with beige to dark gray spots).

Mary Bloom © American Kennel Club

The Anatolian shepherd has a strong, sturdy body.

The Anatolian shepherd originated in Turkey during ancient times. Shepherds developed the breed to guard their sheep. The breed can make an excellent family pet, and is protective of children and property. But it must undergo obedience training and become accustomed to the people and surroundings outside its home.

Critically reviewed by the Anatolian Shepherd Dog Club of America

Anatomy is the study of the biological structure of living things. The term comes from the Greek words meaning *to cut up,* because knowledge of anatomy was first obtained through dissection. The bodies of human beings and animals are so complex that scientists divide anatomy into many branches. *Gross anatomy* is the study of structures that can be seen with the unaided eye. *Microscopic anatomy,* or *histology,* is the study of tissues under a microscope. *Comparative anatomy* compares the structure of different animals. *Embryology* is the study of the development of plants and animals in their earliest stages.

Human anatomy includes the study of the structure of the skeleton, muscles, nerves, and the various organs of the human body. A knowledge of the structure of the body is essential for an understanding of its function in health and disease. Health care professionals must know the structure of the part of the body they expect to treat. Physical education and health science teachers also need to know how the body is built.

In ancient times, people believed that the dead body was a sacred thing. Cutting it up ranked as a serious crime. After 400 B.C., the Greeks allowed occasional dissections. The physician Galen, in the A.D. 100's, described many anatomical structures. But he based his work mainly on dissections of animals and treatment of injured gladiators. After A.D. 1300, dissection and anatomy became a recognized part of medical education in western Europe. In 1543, Andreas Vesalius published his classic work on anatomy, which was based on human dissections. Since then, steady progress has made possible such discoveries as William Harvey's on blood circulation. Because of present knowledge of the body's structure and function, a surgeon can operate on every part of the body. Delmas J. Allen

Anaxagoras, *AN ak SAG uhr uhs* (500?-428 B.C.), was an early Greek philosopher. He argued that, in the beginning, the world was a uniform mixture of all the things that would later emerge during its development. Thus, nothing really comes to be or perishes in the world, and all change is merely rearrangement of the original components. He also argued that matter is infinitely divisible, and that everything has a tiny portion of everything else in it. A thing appears to be the thing that makes up its largest part. Anaxagoras introduced *Mind* as a cosmic principle. He regarded Mind as composed of exceptionally fine and pure matter. Its primary function was to initiate a rotary motion in the original mixture of the world that led to the separation of the various parts. Anaxagoras was born in Clazomenae in Asia Minor (now Turkey) but spent much of his life in Athens. Carl A. Huffman

See also Pre-Socratic philosophy.

Anaximander, *uh NAK suh MAN duhr* (611?-547? B.C.), was an early Greek philosopher. He was one of the first people to describe the world as governed by systematic laws rather than by the actions of the gods. Only one fragment survives from a book he wrote on nature, but we know his views from other ancient authors.

Anaximander believed that the world originated from what he called the *indefinite* or *unlimited.* He probably imagined the indefinite as a substance of no definite character that was unlimited in extent. Opposites such

as hot and cold and dry and wet emerged from the indefinite and came into conflict with one another, thus producing the world. None of the opposites gains the upper hand. This balancing of opposites in part explains such phenomena as the seasons. He anticipated aspects of the theory of evolution by stating that animals came from a moist environment and that human beings originally had fishlike forms. Anaximander was born in Miletus in Asia Minor (now Turkey). Carl A. Huffman

See also **Pre-Socratic philosophy.**

Anaximenes, *an ak SIHM uh neez,* was an early Greek philosopher who lived in Miletus in Asia Minor (now Turkey) during the 500's B.C. Like other Greek philosophers of his time, Anaximenes was interested in giving an account of the natural world. He did so by describing how he believed the universe began, followed by a discussion of astronomy and meteorology. Almost nothing remains of a book he wrote on nature, and we rely for our knowledge of his work on the reports of other ancient authors.

Anaximenes believed that the world developed out of air. He argued that air turned into such substances as water and earth through condensation and into fire through a process called *rarefaction.* Anaximenes's theory may be partly based on the observation of the phenomenon of evaporation. He also believed that human souls consist of air, and he may have chosen air as the original substance of the universe because of this belief.

Carl A. Huffman

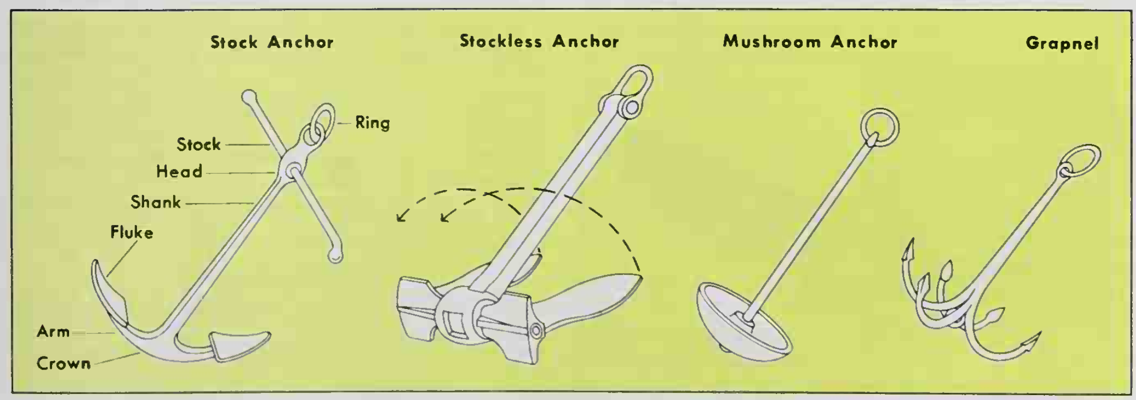
Ancestor worship refers to certain beliefs and practices of families with regard to ancestors who have been dead for many years. In some cultures, deceased ancestors are worshiped as gods. Such worship may involve rituals performed at a shrine decorated with objects that symbolize the ancestor. In many cultures, people believe that the spirits of ancestors are angered by violations of law or custom, and they use rituals to pacify them. These rituals commonly include offerings of food and other items. Ancestor worship forms a part of many religions, especially in Asia and Africa. In general, it serves to uphold the authority and honor of elders, to keep the family together, and to maintain the society's traditions. Edward O. Henry

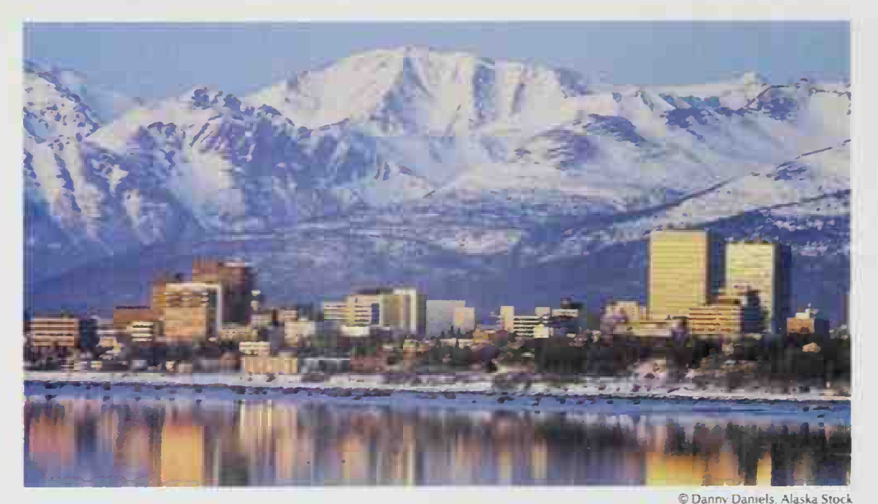
Ancestry. See **Genealogy.**

Anchor is a heavy weight used to hold a ship or boat in place. A rope or chain is fastened to the anchor and tied to the ship. When the anchor is lowered, it generally catches at the bottom of the water to keep the vessel in place. An anchor may be as simple as a rock tied to the end of a line. The most common kinds of anchors are made of iron or steel.

Anchors come in a wide variety of shapes and sizes. The shape depends in part upon the expected composition of the land at the bottom of the water. For example, when the bottom is mud, a small boat may be held in place by a *mushroom anchor,* a cast-iron bowl on the end of a shank. But for a rock bottom, the boat would be secured with a *grapnel,* an anchor with several hooks on the end of its shank. The size of the anchor depends mainly on the size of the craft. A huge aircraft carrier may use an anchor weighing more than 60,000 pounds (27,200 kilograms). Anchors are essential for navigation buoys, which must remain in one place at all times and in all kinds of weather. Buoys are held to the bottom by anchors made of concrete. Robert L. Scheina



Anchorage (pop. 260,283) is Alaska's largest city in population and the state's main center of commerce and transportation. It is also a chief United States defense center. Anchorage is one of the largest U.S. cities in area. It covers 1,958 square miles (5,071 square kilometers). It lies on Cook Inlet in south-central Alaska, west of the Chugach Mountains (see **Alaska** [political map]).



Anchorage is a modern city with high-rise buildings, hotels, and shopping malls. An extensive system of bicycle paths extends in and around the city. Anchorage International Airport serves as an important transfer point for both passengers and freight bound for other destinations. The city is a chief Alaskan port. The Alaska Railroad, a freight and passenger line, has its headquarters in Anchorage. Attractions include an art and history museum and the Alaska Center for the Performing Arts. The center is the home of the Anchorage Symphony, the Anchorage Opera, and the Alaska Light Opera. Alaska

Some common anchors

These illustrations show four common kinds of anchors: the *stock anchor,* the *stockless anchor,* the *mushroom anchor,* and the *grapnel.* The stock and stockless anchors are used chiefly on large vessels. The mushroom anchor and the grapnel are used to hold small boats in place.

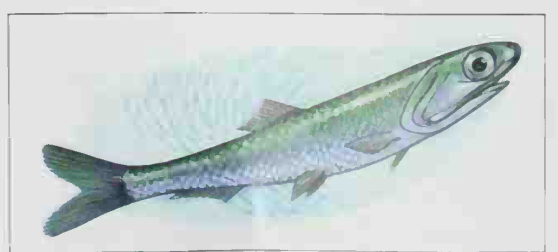
Pacific University and a campus of the University of Alaska are also in Anchorage. Just outside Anchorage are two major military installations--Elmendorf Air Force Base, and Fort Richardson, an Army post. Anchorage is the administrative center of Alaska's oil industry.



Athabaskan Indians lived in what is now the Anchorage area before white settlers arrived. Anchorage was founded in 1914 as the construction center of the Alaska Railroad. The town, originally called Ship Creek and then Woodrow, was renamed Anchorage in 1915. Its people chose that name because ships anchored there with supplies for the railroad.

The city began to grow quickly after the two military bases opened in 1940, during World War II. The discovery of oil south of the city in 1957 led to further growth. On March 27, 1964, one of the worst earthquakes in the history of North America hit the Anchorage area. It killed 131 people and caused $750 million in damage.

In 1975, Anchorage merged with several other communities to form an expanded city known officially as the Municipality of Anchorage. The construction of the Trans-Alaska Pipeline in 1977 provided a strong boost to the economy. In 2000, government officials passed "Anchorage 2020," a comprehensive plan that will manage the city's future growth. Anchorage has a mayor-council form of government. F. Patrick Fitzgerald

See also Alaska (Climate; picture).

Anchovy is a popular food fish related to the herring. Anchovies are used in salads, pizza, and sauces, and they are often canned, dried, or made into a paste. Some people eat freshly cooked anchovies.

WORLD BOOK illustration by John F. Eggert

The anchovy is a popular food fish.

Anchovies have tender, oily flesh. Most anchovies measure less than 4 inches (10 centimeters) long. The fish have large eyes and a long snout that sticks out far beyond their lower jaw. An anchovy has a silvery underside and a green or blue back. Most species have blue or silver bands along their sides.

Anchovies travel in large schools. Most live in the shallow coastal waters of warm tropical regions. Large quantities of the fish are caught in the Mediterranean Sea and along the coast of Peru in South America. The type of anchovy caught along the Peruvian coast is sometimes called an *anchovetta.* It is used mainly in animal feed or as fish bait. Robert R. Rofen

Scientific classification. Anchovies belong to the family Engraulidae. The European anchovy is *Engraulis encrasicholus,* and the Peruvian anchovy is *E. ringens.* The northern anchovy that lives off the west coast of North America is *E. mordax.* The bay anchovy that ranges from Cape Cod, Massachusetts, to the Yucatán Peninsula, in Mexico, is *Anchoa mitchelli.*

Ancient civilization refers to civilizations that flourished long ago. The term is used especially for the way of life that existed around the Mediterranean Sea beginning before 3000 B.C. and ending with the fall of Rome in A.D. 476. It includes great civilizations developed by the Assyrians, Egyptians, Israelites, and Persians. The cultures of ancient Greece and Rome are also considered part of it. But great early civilizations also grew in the Far East, India, central and southern Africa, and North and South America. Barbara Mertz

Andersen, Hans Christian (1805-1875), was Denmark's most famous author. His fairy tales are among the most widely read works in world literature. His stories of make-believe have enchanted young readers around the world for generations.

Andersen wrote with wisdom, deliberate simplicity, and often with sly humor. Like Jonathan Swift's *Gulliver's Travels,* Andersen's fairy tales can be considered both children's literature and adult literature. Many of Andersen's fairy tales have serious moral meanings that are intended for adults.

Andersen gave each tale its own style, but his stories can be roughly classified into four groups. These groups are (1) imitations of folk tales ("The Tinder Box," "Little Claus and Big Claus," and "The Traveling Companion"); (2) tales based on Andersen's life ("The Ugly Duckling" and "She Was Good for Nothing"); (3) tales that make fun of human faults ("The Emperor's New Clothes" and "The Rags"); and (4) philosophical tales ("The Story of a Mother" and "The Shadow"). Some of the tales use settings in Denmark ("The Wind Tells About Valdemar Daae and His Daughters" and "Holger Danske"), but others can take place anywhere.

Andersen was born in Odense. He was the son of a poor shoemaker who died when Hans was 11 years old. After attending the city school for poor children, Andersen left Odense at the age of 14 to seek a career as an artist in Copenhagen. He nearly starved while trying to earn a living as an actor, singer, and dancer. In Copenhagen, he received help from Jonas Collin, who became his lifelong friend. Collin got him a royal scholarship, which permitted Andersen to continue his education from 1822 to 1828.

In 1829, his first play, *Love in St. Nicolai Church Tower,* was produced. For several years, Andersen's reputation as a writer rested on his many plays and novels. But his plays are no longer produced. His novels, the best of which is *The Improvisation* (1835), are now seldom read outside of Scandinavia.

Andersen published the first of his 156 fairy tales in 1835 and continued writing them until he died. They first appeared in a series of pamphlets and later were collected and published in books. The stories became popular in the early 1840's, and made Andersen famous. His acquaintances included royalty and such fellow artists as the composer Franz Liszt, the poet Heinrich Heine, and the novelists Charles Dickens and Victor Hugo.

Andersen traveled throughout Europe and wrote many lively books about his experiences. *A Poet's Bazaar* (1842) and *In Sweden* (1851) are probably his best travel books. He also wrote an autobiography called *The Fairy Tale of My Life* (1855).

Andersen was a sensitive man who eagerly sought fame and success. He never married, although he fell in love with three women, including the Swedish singer Jenny Lind and the daughter of Jonas Collin. None of the women returned his love. But Andersen won admiration and fame for his writing. Niels Ingwersen

Anderson, Carl David (1905-1991), an American physicist, discovered two subatomic particles—the *positron* and the *muon.* He identified these particles while studying cosmic rays with the aid of a Wilson cloud chamber (see **Cosmic rays**). For his discovery of the positron, Anderson shared the 1936 Nobel Prize in physics with Victor F. Hess.

The positron, which Anderson discovered in 1932, was the first known antiparticle (see **Antimatter**). The positron has a mass equal to that of the negatively charged electron, but its electric charge is positive. In 1937, Anderson discovered the particle now known as the muon. Muons have positive or negative charges and closely resemble positrons and electrons. But a muon's mass is about 207 times as great as that of an electron.

Anderson was born in New York City. In 1930, he received a Ph.D. degree in physics from the California Institute of Technology. Robert H. March

See also **Dirac, Paul A. M.; Meson.**

Anderson, Judith (1898-1992), ranked among the leading English-speaking actresses of the 1900's. Anderson was a character actress and interpreter of intensely emotional roles who appeared in a great variety of parts. Her greatest stage successes included *Strange Interlude* (1928), *Mourning Becomes Electra* (1931), *Macbeth* (1941), and *Medea* (1947). Her major films included *Rebecca* (1940) and *King's Row* (1941).

Anderson was born in Adelaide, Australia. Her real name was Frances Margaret Anderson. Queen Elizabeth II named her Dame Commander of the Order of the British Empire in 1960, and she became known as Dame Judith Anderson. She was the first Australian actress so honored. Don B. Wilmeth

Anderson, Marian (1897-1993), was an African American contralto. She gained fame primarily as a concert singer. In 1955, Anderson became the first black soloist to sing with the Metropolitan Opera of New York City. The famous conductor Arturo Toscanini praised her voice as one "that comes once in a hundred years."

Anderson was born in Philadelphia and sang in church choirs during her childhood. After graduating from high school, she studied voice and began to make concert tours. Anderson then spent several years studying and performing in Europe, where her singing won wide praise. She became a top concert singer in the United States after performing at Town Hall in New York City in 1935.

Racism affected Anderson's career. In 1939, the Daughters of the American Revolution would not let her perform in Constitution Hall in Washington, D.C., because she was black. She sang instead at the Lincoln Memorial for over 75,000 people. Anderson won the Spingarn Medal that year. She was a U.S. delegate to the United Nations (UN) in 1958 and won the UN peace prize in

Franz Rupp
Marian Anderson

1977. *My Lord, What a Morning* (1956) is her autobiography. Thomas Bauman

Anderson, Maxwell (1888-1959), an American playwright, brought seriousness and idealism to the theater. He wrote several realistic plays, including the war drama *What Price Glory?* (with Laurence Stallings, 1924) and the psychological melodrama *The Bad Seed* (1955). But his major contributions were historical plays, verse dramas, and his attempts to revive traditional heroic tragedy in the modern theater.

Among Anderson's historical plays, *Elizabeth the Queen* (1930) is one of the most significant. This tragedy in verse is based on the romance of Queen Elizabeth and Lord Essex. Like many of Anderson's works, it pictures the defeat of good by the inevitable forces of evil, but it also praises the counterforces of nobility and love in humanity. *Winterset* (1935), his most enduring play, is based on the Sacco-Vanzetti case (see **Sacco-Vanzetti case**). But it mainly deals with the dilemma created when love conflicts with a crusade for justice against evil. Another verse tragedy, *Key Largo* (1939), explores the difficulties of deciding to fight evil, as symbolized by a gangster. Anderson won the 1933 Pulitzer Prize for his political satire *Both Your Houses* (1933).

Anderson was born in Atlantic, Pennsylvania. In 1938, he helped found the Playwrights' Company, which produced many notable plays. Thomas P. Adler

Anderson, Sherwood (1876-1941), was an American short-story writer and novelist. Although none of his novels was wholly successful, several of his short stories have become classics. Anderson was a major influence on the generation of American writers who came after him. These writers included Ernest Hemingway, F. Scott Fitzgerald, and William Faulkner. Anderson thus occupies a place in literary history that cannot be fully explained by the literary quality of his work.

Schaal Pix: Harcourt, Brace

Sherwood Anderson

Anderson was born in Camden, Ohio. He never finished high school because he had to work to support his family. By 1912, he was the successful manager of a paint factory in Elyria, Ohio, and the father of three children by the first of his four wives. In 1912, Anderson deserted his family and job. In early 1913, he moved to Chicago, where he devoted more time to his imaginative writing. He became a heroic model for younger writers because he broke with what they considered to be American materialism and convention to commit himself to art.

Anderson's most important book is *Winesburg, Ohio* (1919), a collection of 22 stories. The stories explore the lives of inhabitants of Winesburg, a fictional version of Clyde, Ohio, the small farm town where Anderson lived for about 12 years of his early life. These tales made a significant break with the traditional American short story. Instead of emphasizing plot and action, Anderson used a simple, precise, unsentimental style to reveal the frustration, loneliness, and longing in the lives of his characters. These characters are stunted by the narrowness of Midwestern small-town life and by their own limitations.

In *Winesburg, Ohio,* Anderson became one of the first American writers to use modern psychological insights, especially those of the Austrian psychiatrist Sigmund Freud. Anderson's characters tend to make themselves into what the author called *grotesques.* Anderson believed that there were once hundreds of truths, all of them beautiful. But people tended to adopt only one truth and call it theirs. According to Anderson, the moment "one of the people took one of the truths to himself, called it his truth, and tried to live his life by it, he became a grotesque and the truth he embraced became a falsehood."

Anderson's most important book after *Winesburg, Ohio* is the short-story collection *The Triumph of the Egg* (1921). His many novels include *Poor White* (1920) and *Dark Laughter* (1925). He also wrote several volumes of revealing autobiography. Daniel Mark Fogel

Andersonville. See **Civil War** (Prisons).

Andes Mountains, *AN deez,* are the world's longest chain of mountains above sea level. They stretch along the entire west coast of South America from Cape Horn to Panama and Venezuela for a distance of 4,500 miles (7,200 kilometers).

Only the Himalaya of northern India and Tibet are higher than the Andes range. Many Andean peaks rise over 20,000 feet (6,100 meters) high. The chain is about 400 miles (645 kilometers) wide across its widest part. In Spanish, the Andes are called *Cordillera de los Andes,* which means *Andes Mountain Range.*

Physical features. The Andes may be divided into three natural regions: southern, central, and northern.

The southern Andes are less than 10,000 feet (3,000 meters) high near the southern tip of the continent. Farther north, the peaks are higher. Aconcagua (22,831 feet, or 6,959 meters) is the highest peak in the Americas. It stands in Argentina, about 65 miles (105 kilometers) from Santiago, Chile.

The central Andes form the broadest part of the mountain system. Two ranges running northwest and southeast make up this section. Between these ranges lie the wide, high plains, or plateaus, of Peru and western Bolivia. The plateaus themselves lie about 13,000 feet (4,000 meters) above sea level. Farther north, the two ranges draw closer together. The highest peaks of the central Andes include Pissis (22,241 feet, or 6,779 meters), Huascarán (22,205 feet, or 6,768 meters), Sorata or Illampu (21,276 feet, or 6,485 meters), Sajama (21,463 feet, or 6,542 meters), Illimani (21,004 feet, or 6,402 meters), Chimborazo (20,561 feet, or 6,267 meters), and Cotopaxi (19,347 feet, or 5,897 meters).

The northern Andes have three ranges of mountains. None of these ranges rise as high as the mountains farther south. One range runs along the coast through Colombia and into Panama. The central range is located between the narrow valley of the Cauca River and the valley of the Magdalena River. This range includes the volcano of Tolima (17,110 feet, or 5,215 meters). The third range, on the east, runs northeast into Venezuela. Many mountain peaks in the northern Andes reach 15,000 feet

(4,570 meters) or more. The highest peak is Cristóbal Colón (18,947 feet, or 5,775 meters) in Colombia.

Volcanoes and earthquakes. Many of the high mountains of the Andes are volcanoes. Some of them are active. The most famous of these volcanoes are Cotopaxi, Tungurahua, and Sangay in Ecuador and Nevado del Ruiz in Colombia. Earthquakes are common in the Andes. Many towns have been wiped out by them. Cities that have been greatly damaged by earthquakes include Valparaíso, Chile; Lima and Callao, Peru; Popayán, Colombia; and Quito, Ecuador.

Glaciers, lakes, and rivers. Glaciers cover many of the high peaks of the Andes, even those close to the equator. The largest glaciers are in southern Chile. Others reach down to the Pacific Coast. Many of the glaciers in the southern Andes have cut deep valleys into the rocky coastline. These valleys go far below the water level and make the coastline ragged like that of Norway. Many deep inlets and rocky islands lie along the coast. Rivers flow into the Pacific through gaps cut by glaciers on the west side of the Andes.

Many of the chief headstreams of the Amazon River rise on the eastern slopes of the Andes. Two other great rivers, the Paraná and the Orinoco, also receive tributaries from the Andes. Rainfall is light on the western slopes of the Andes, except in the section north of the equator and in the southern third of Chile.

Nature has played an unusual prank in the section between the two ranges of the central Andes in Bolivia and northern Argentina. Water from the high plateau does not flow to the Atlantic or the Pacific. Instead, it collects in Lake Titicaca, and then flows into Lake Poopó. The level of this lake has fallen below its outlet. Now water can escape only through evaporation, or, when the water is high, it overflows into a swamp.

Natural resources. The name Andes is believed to have come from *anti,* the Quechuan word for copper. Much copper is found in the mountains. The Andes also contain gold, silver, tin, lead, iron, platinum, and quicksilver. Many kinds of wild animals live in the mountains, including squirrellike chinchillas, condors, deer called huemul, and members of the camel family called vicuña. Llamas and alpacas, which were tamed in prehistoric times, graze in the Central Andes in the high grasslands called *puna* or *paramos.* Below the grasslands, farmers have removed many forests. They have created large terraces and irrigation systems, and they grow such crops as potatoes, corn, and coffee.

Transportation. The passes of the Andes Mountains are narrow, steep, and winding. The mountains are so high and rise so sharply from low plains that they divide the continent into Pacific South America and Atlantic South America. Engineers find railroads much harder to build in the Andes Mountains than in the Rocky Mountains. In the central Andes, engineers have had to climb more than 10,000 feet (3,000 meters) to find a pass suitable for a railroad.

Four railroads run up the west slope to the rich mineral beds on the plateaus of Peru and Bolivia. One of these, the Central Railway, climbs to over 15,800 feet (4,816 meters) above sea level. It is the highest standard gauge railroad in the world.

In Peru, a paved highway runs from Callao on the west coast to Cerro de Pasco, over 100 miles (160 kilometers) inland. From here, an all-weather road continues down a deep canyon in the eastern Andes to a branch of the Amazon River. Other highways lead over the Andes into the eastern lowlands. Trucks, buses, and automobiles travel over these roads.

Flying also provides an important means of travel in the Andes. Regular flights link Santiago, Chile, and Buenos Aires, Argentina. Large passenger planes fly through foggy, 12,674-foot (3,863-meter) Uspallata Pass. Above this pass, passengers may look down and see the "Christ of the Andes." This huge statue, put up by Argentina and Chile, marks the settlement of a boundary

Chip and Rosa Maria Peterson

The Andes Mountains stretch along the west coast of South America. Many Andean peaks rise more than 20,000 feet (6,100 meters) above sea level.

Andorra, one of the smallest countries in the world, lies high in the Pyrenees mountains between France and Spain. The official name of Andorra in Catalan, a language that closely resembles the Provençal spoken in southern France, is Valls d'Andorra (Valleys of Andorra). Andorra la Vella (Andorra the Old), a town of about 22,000 people, is the capital.

Many tourists visit Andorra each year. They enjoy the mountains' rugged beauty, the old churches, and the quaintness of the country. Many people also go to Andorra each year to buy goods that are relatively inexpensive because Andorra charges almost no tax on them.

The steep, rocky mountains that surround Andorra cut the country off from the rest of the world for hundreds of years. As a result, Andorra's boundaries have changed little since the Middle Ages. Andorra's legal system is based on ancient laws and *common law* (rules based on customs) that date from the Roman Empire.

Government. Andorra is a parliamentary coprincipality. Until 1993, the bishop of Urgel, Spain, and the president of France ruled Andorra jointly under treaties signed in the 1200's. Both rulers, known as the "princes of Andorra," had to agree before any changes could be made in Andorra's government. Each prince had the right to veto laws made by the parliament.

In 1993, Andorra's citizens adopted their first constitution. It made elected officials responsible for governing Andorra. The role of the princes became mostly ceremonial. But the princes still must approve international treaties with France and Spain, and some other matters concerning boundaries, defense, and internal security.

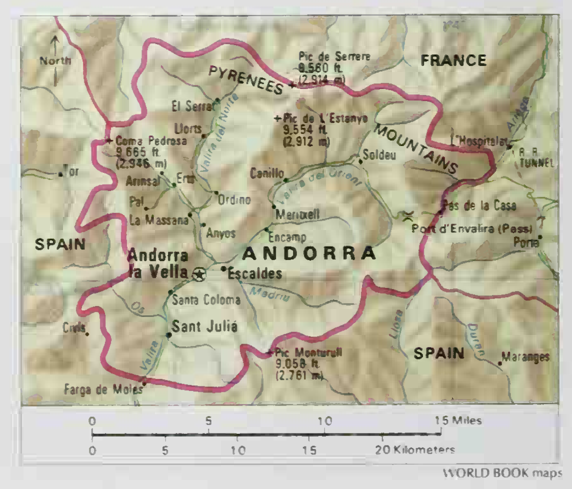
Under the Constitution, a prime minister heads the government. The people elect the prime minister. The prime minister selects an Executive Council of four to six counselors to help administer the government. A 28-member parliament known as the General Council of the Valleys makes the nation's laws. Two members are elected from each of Andorra's seven *parishes* (districts), and the other 14 members are elected nationwide.

Since Andorra had two rulers for hundreds of years, it often has two sets of public services. For example, it has two postal systems—one French and one Spanish. Both the French franc and the Spanish peseta served as *legal tender* (lawful money). They were replaced by the euro, Europe's common currency, in 2002.

People. From the 1100's to the 1930's, life in Andorra changed little. The people worked as farmers and shepherds. The villages and parishes owned the grazing lands, and farmers owned their own cropland. To keep the cropland from being divided into tiny plots, farmers gave at least three-fourths of their inheritance to one of their children, usually the oldest son. Many of the other children had to move out of Andorra. As a result, more people of Andorran descent now live in France and Spain than in Andorra.

The opening of roads to France and Spain in the 1930's and the sudden growth of tourism in the 1950's changed some of the old ways of living. Many who had worked as farmers, shepherds, and smugglers became storekeepers and hotel owners. Tourists brought new wealth, and fewer people had to move out of the country. Some people from Spain have moved into Andorra. Today, only about one-third of the country's people are Andorran citizens. Over half are citizens of Spain. Other inhabitants are mainly from France and Portugal.

These changes weakened the strong control Andorran fathers had always held over their families. But in other ways life has changed little. Life for the average Andorran still centers around the family. Many Andorrans still live in big farmhouses with stone walls and rough slate roofs. Most of these houses are three stories high with a barn to house livestock or a tool shed on the ground floor, a living room and kitchen on the second



Facts in brief

Capital: Andorra la Vella.
Official language: Catalan.
Area: 175 mi² (453 km²). *Greatest distances*—north-south, about 16 mi (26 km); east-west, about 19 mi (31 km).
Elevation: *Highest*—Coma Pedrosa, 9,665 ft (2,946 m) above sea level. *Lowest*—2,756 ft (840 m) above sea level.
Population: *Estimated 2002 population*—69,000; density, 394 per mi² (152 per km²); distribution, 95 percent urban, 5 percent rural. *1996 official estimate*—72,766.
Chief products: *Agriculture*—potatoes, tobacco. *Manufacturing*—cigarettes and other tobacco products.
Flag: The national flag, used by the people, has blue, yellow, and red vertical stripes. The state flag, used by the government, has a coat of arms on the yellow stripe. See **Flag** (picture: Flags of Europe).
Money: *Basic unit*—euro. One hundred cents equal one euro. The French franc and Spanish peseta were taken out of circulation in 2002.

floor, and bedrooms opening onto wooden or iron balconies on the third floor. The people speak Catalan, but most Andorrans also understand French and Spanish. The government prints its official documents in Catalan.

Almost all Andorrans are Roman Catholics, and their religion greatly influences their social life. All public records are kept by the church, and only Roman Catholics can get married in Andorra. On their national holiday, September 8, Andorrans make a *pilgrimage* (journey) to the shrine of Our Lady of Meritxell, patron saint of Andorra.

Children in Andorra must attend school from ages 6 to 16. Andorra has Andorran, French, and Spanish schools.

Land. Steep mountain peaks as high as 9,665 feet (2,946 meters) above sea level tower over the valleys of Andorra. Fields and meadows lie in the valleys, and oak, pine, and fir trees cover the lower mountain slopes. Only grass grows farther up the mountainsides. The *Valira del Norte* (Northern Valira) and the *Valira del Orient* (Eastern Valira) rivers meet near the town of Andorra la Vella to form the Valira River, which flows into Spain. The main roads in Andorra follow the Valira del Norte toward France and the Valira into Spain.

Andorra has a dry, sunny climate. Three or four heavy snows fall each year, and even powerful snowplows cannot keep the mountain road between Andorra and France open all winter. However, in the valleys south of Escaldes, the snows melt in a few days. Winter temperatures at Escaldes range between 20 and 30 °F (−7 and −1 °C). In the summer, the valleys are warm during the day and cool at night. Temperatures at Escaldes reach 70 to 80 °F (21 to 27 °C).

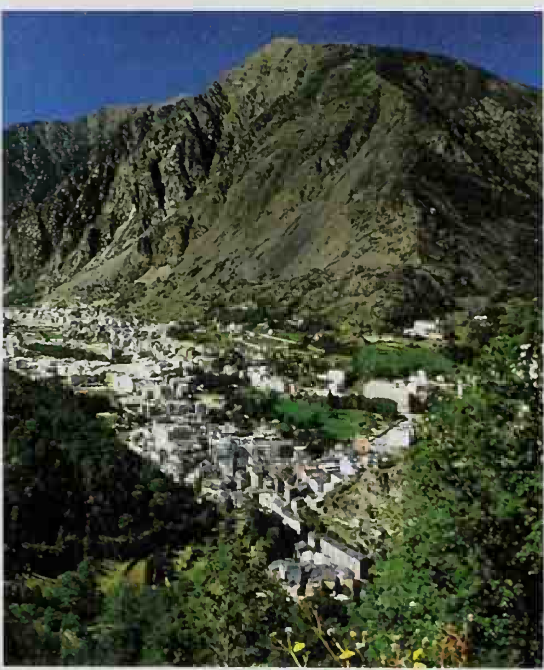
Economy. Tourism is Andorra's chief source of income. Andorra's beautiful mountains and ancient buildings are the main attractions. Ski slopes have been opened at Pas de la Casa and Soldeu, where the snow lasts until the end of April. Tourists can buy Swiss watches, Japanese cameras, French wines, clothing, and other goods at low prices in Andorra, because import *duties* (charges) are low.

A few Andorrans farm. Their main crop is tobacco. About half the tobacco is raised in the lower valleys of Sant Juliá's parish. Most of the mountain slopes are used for grazing sheep and cattle. In some areas, farmers have carved terraces into the mountainsides as high as 5,300 feet (1,620 meters) above sea level. Potatoes are the chief crop raised on the terraces. Other mountain crops include buckwheat, corn, oats, and rye.

History. According to legends, Charlemagne either founded or freed Andorra. The first known ruler of Andorra was a Spanish noble, the Count of Urgel. He controlled the region in the A.D. 800's, and then gave it to the diocese of Urgel. In the 1000's, the bishop of Urgel could not control Andorra by himself, and he asked a Spanish noble, the Lord of Caboet, to defend the region. A French noble, the Count of Foix, inherited the lord's duties through marriages. The French count and the bishop fought over Andorra. They finally ended their disputes by signing treaties in 1278 and 1288. The treaties made them joint rulers.

Through marriages, the king of France inherited the count's rights. During the French Revolution, France refused to rule Andorra. But the Andorrans later asked Napoleon I to rule them, and he accepted in 1806. France's head of state has been a prince of Andorra since then. Today, the French president serves as prince. Until 1993, as the old treaties required, Andorra paid about $2 every other year to the president of France and about $8 to the Spanish bishop. The bishop also got 6 hams, 6 cheeses, and 12 hens every other year.

In the 1800's, Andorran farmers began raising tobacco. Until the 1900's, many Andorrans made their living by smuggling tobacco into France and Spain.



Until the 1930's, only male citizens who were the heads of households could vote in Andorra. In 1933, Andorran youths stormed the General Council and forced it to give all male citizens over 25 years old the right to vote. In 1970, the voting age was reduced to 21 and female citizens won the right to vote. In 1984, a woman was elected to the General Council for the first time. In 1985, the voting age was lowered to 18.

In 1993, the people of Andorra adopted their first constitution. The constitution strictly limited the role of the princes in the government and placed responsibility for governing Andorra in the hands of an elected prime minister and parliament. William M. Reddy

Andorra la Vella, *an DAWR uh lah VEHL yah* (pop. 21,630), is the capital and largest town of Andorra. About one-third of Andorra's people live in Andorra la Vella. The town lies beside the Valira River in a valley high amid the Pyrenees. For location, see Andorra (map).

The economy of Andorra la Vella depends on tourism. Many visitors come from neighboring Spain and France. The town has numerous medieval structures, including the Santa Coloma church. Andorra's

Cameramann International, Ltd. from Marilyn Gartman

Andorra's capital, called Andorra la Vella, nestles among the rocky peaks of the Pyrenees mountains. The quaint old town has become a leading tourist center.

parliament meets in the Casa de la Vall, which dates from the 1500's.

For hundreds of years, the Pyrenees kept Andorra la Vella isolated from the outside world. After the mid-1900's, however, modernization proceeded rapidly. Today, the city bustles with commercial activity, and air pollution sometimes clouds the valley. William M. Reddy

Andrada e Silva, *an DRAH duh ee SEEL vuh,* **José Bonifácio de,** *zhoh ZEH BOH nee FAH syoo duh* (1763-1838), was a Brazilian statesman known as the "architect of Brazilian independence." He supported land reform, the ending of slavery, and rule by a monarchy. In 1822, he guided Brazil out of the Portuguese empire, and served the new emperor, Pedro I. He fell from favor and was banished temporarily. Pedro later named him guardian of his son, the future Pedro II (see **Pedro I; Pedro II**).

Andrada was also an accomplished scientist. In 1783, he went to Portugal to study philosophy and law at the University of Coimbra. In 1790, the king sent him on a 10-year tour. He studied chemistry in Paris, and mining and metallurgy in Germany, Norway, Switzerland, and England. He taught at the University of Coimbra and held important government posts. Andrada returned to Brazil in 1819. He was born in Santos, Brazil.

Robert M. Levine

André, *AHN dray,* **John** (1751-1780), a British officer, was hanged as a spy by the American Revolutionary Army. He was the messenger of the British general, Sir Henry Clinton, who, with Benedict Arnold, had concocted a plot for taking the vital American fort at West Point (see **Arnold, Benedict**).

André was Clinton's personal aide and adjutant general of the British forces in America. Clinton chose him to meet Arnold and arrange the final details of the plot for taking West Point. Clinton sent him up the Hudson River on a British sloop. The men met on shore on the night of Sept. 21, 1780.

At dawn, the Americans opened fire on the sloop and forced it to retreat. André, caught inside the American lines, was forced to go overland to New York. Disobeying Clinton's instructions, he discarded his military uniform for civilian clothes. By this action, André lost his chance, if captured, to be considered an officer instead of a spy. Not far from the British outposts, André was stopped by American militia, who searched him and found papers that Arnold had given him. He was taken to the nearest officer, who notified Arnold. This gave Arnold a chance to escape.

André was tried by a military court and sentenced to death. In spite of Clinton's efforts to save him, he was hanged on October 2.

André was born in London. He was handsome, witty, interested in literature and music, and popular in the British army. While in prison, he won the affection even of his American captors. His youth, charm, and courage in facing death make his story one of the tragedies of the war. Paul David Nelson

Andretti, *an DREHT tee,* **Mario** (1940-), became one of America's finest automobile racing drivers. Andretti won the Grand Prix world driving championship in 1978. He won the Daytona 500 race for stock cars and the Indianapolis 500 race in 1969. Andretti won the United States Auto Club national driving championship in 1965 and 1966. In 1966, he finished first in eight of the races that made up the U.S. championship circuit. He won the national championship in 1969 and in 1983. Andretti is the only driver who has won the Grand Prix world driving championship, the Daytona 500, and the Indianapolis 500. He retired from Indy car racing in 1994.

Andretti was born near Trieste, a city on the Adriatic Sea. He spent more than three years in a displaced persons camp after World War II, and moved to the United States in 1955. Michael Andretti, his son, is also a leading racing driver. Sylvia Wilkinson

Andrew, Saint, was the first of the 12 apostles of Jesus Christ. He was the brother of the apostle Peter. Andrew was a fisherman from Bethsaida, a village on the north shore of the Sea of Galilee. In Matthew 4: 19, Jesus calls Andrew and Peter to become "fishers of men."

In the Gospel of John, Andrew is described as a follower of Saint John the Baptist before becoming a disciple of Jesus. The Gospel tells that Andrew was present at the feeding of the multitude and received a request from "certain Greeks" who wanted to meet with Jesus.

According to later tradition, Andrew preached in Asia Minor and Greece, and he may have preached in what is now Ukraine. He was martyred in Greece by being crucified on an X-shaped cross. Andrew became the patron saint of Greece, Russia, and Scotland. The X on the Scottish flag is a symbol of his crucifixion. His feast day is November 30. Richard A. Edwards

See also **Apostles**.

Andrews, Roy Chapman (1884-1960), was well known as an author and explorer, and as a leader of expeditions for the American Museum of Natural History. As a result of work from 1908 to 1914 in Alaska and Asia, he became an authority on whales. Between 1916 and 1930, Andrews led expeditions to central and eastern Asia. In the Gobi Desert, he and his co-workers found the remains of *Baluchitherium,* the largest land mammal that ever lived. They also discovered the first dinosaur eggs ever found and unearthed evidence of a prehistoric civilization.

Andrews was born in Beloit, Wisconsin, and he graduated from Beloit College. He served as director of the American Museum of Natural History from 1935 to 1942. He wrote several books, including *Whale Hunting with Gun and Camera* (1916), *The New Conquest of Central Asia* (1932), and *Beyond Adventure* (1954). G. J. Kenagy

Andrews Air Force Base, Maryland, is the headquarters of the Air Force Systems Command. The command develops and buys aircraft, missiles, and other weapon systems for the United States Air Force. Several passenger aircraft are kept at the base for the use of the president and other government officials. Andrews Air Force Base covers about 5,000 acres (2,000 hectares) southeast of Washington, D.C. The base was established in 1943. It was named for Lieutenant General Frank M. Andrews, who died in an aircraft accident.

Wayne Thompson

Andreyev, *ahn DREH yuhf,* **Leonid,** *leh ah NEET* (1871-1919), was a Russian prose writer and dramatist. Andreyev created moods of extreme pessimism and despair in most of his works. A number of his writings deal with the themes of loneliness and human suffering. His best-known short story, "The Red Laugh" (1904), explores the horror and terror of war. The short novel "The Seven

That Were Hanged" (1908) examines the feelings of five revolutionaries and two murderers as they await their executions.

Andreyev's most popular plays were *The Life of Man* (1906) and *He Who Gets Slapped* (1915). Leonid Nikolayevich Andreyev was born in Orel. See also **Russian literature** (Symbolism). Anna Lisa Crone

Androcles, *AN druh kleez,* also called Androclus, was a Roman slave who ran away from his master and hid in a cave. He took a thorn from the paw of a suffering lion. Later, Androcles faced the same lion in the Roman arena. The lion recognized him and refused to harm him. George Bernard Shaw's play *Androcles and the Lion* (1912) is based on this story. Elaine Fantham

Andromeda, *an DRAHM uh duh,* is a constellation of the northern celestial hemisphere. It extends from the constellation Perseus to the northeast corner of the great square of the constellation Pegasus. The brightest star of Andromeda, called Alpheratz, completes the square of Pegasus. The Andromeda Galaxy, which is a spiral galaxy close to our solar system, is visible as a faint, misty spot in the Andromeda constellation. See also **Andromeda Galaxy.** David H. Levy

Andromeda, *an DRAHM uh duh,* in Greek mythology, was the daughter of Cassiopeia and Cepheus, rulers of Ethiopia. Cassiopeia dared to compare her own beauty to that of the *Nereids* (sea nymphs) who attended Poseidon. In anger, Poseidon sent a sea monster to attack Ethiopia. An oracle said Andromeda should be sacrificed to the serpent to save the land. Perseus saw Andromeda chained to a rock, fell in love with her, and killed the monster. He then married Andromeda. Among their descendants was Hercules. After her death, Andromeda became a constellation. Jon D. Mikalson

Andromeda Galaxy, *an DRAHM uh duh,* is the spiral galaxy that is closest to our home galaxy, the Milky Way. Like the Milky Way—which is also a spiral galaxy—the Andromeda Galaxy contains a few hundred billion stars. But it appears in the sky as an oval *nebula* (a fuzzy patch of light), even when viewed with a high-quality pair of binoculars. It looks fuzzy because it is so far away. The Andromeda Galaxy is about 2 million *light-years* from the earth. A light-year is the distance that light travels in a vacuum in a year—about 5.88 trillion miles (9.46 trillion kilometers). The Andromeda Galaxy is named for the constellation in which it appears. The galaxy is also known as the Great Nebula in Andromeda and as M31.

© Jason Ware, Galaxy Photography

The Andromeda Galaxy has a large central bulge, a thin disk of stars, and spiral arms. Our home galaxy, the Milky Way, has similar features but is slightly smaller than Andromeda.

The galaxy has a thin, circular disk of stars, all of which rotate about its center. It also has a large central bulge. The disk has two prominent spiral arms consisting of stars. Next to the arms are dark lanes of dust and gas. Surrounding the galaxy is a halo of hundreds of globular star clusters.

The disk is greatly tilted with respect to the line of sight from the earth. The tilt accounts for the galaxy's oval appearance when viewed from the earth.

The Andromeda Galaxy played a key role in the history of astronomy. In 1924, American astronomer Edwin Hubble discovered individual *variable stars* (stars whose brightness changes) there. At that time, astronomers did not know of any galaxy other than the Milky Way. However, they had found that many nebulae (the plural of *nebula*), including the Great Nebula in Andromeda, have a spiral shape. Hubble's discovery indicated that the Great Nebula is far beyond the Milky Way, and that all spiral nebulae are vast collections of stars at great distances and therefore separate galaxies. Mark Morris

See also **Galaxy; Milky Way; Nebula.**

Andropov, *ahn DRAHP awf,* **Yuri Vladimirovich,** *YOO rih vluh DYEE myih* RAW *vyihch* (1914-1984), served as general secretary of the Communist Party of the Soviet Union from November 1982 until his death in February 1984. The post of general secretary was the most powerful in the Soviet Union at the time. Andropov also served as chairman of the Presidium of the Supreme Soviet—the Soviet Union's head of state at the time—from June 1983 until his death. Andropov had been head of the country's secret police, the KGB, from 1967 until May 1982. He then became a member of the Secretariat of the Central Committee of the Communist Party.

Andropov was born in Nagutskaya, a town in the Stavropol region between the Black and Caspian seas. His early career was spent in *Komsomol* (Young Communist League) activities. Andropov joined the Communist Party in 1939. From 1953 to 1957, he served as Soviet ambassador to Hungary. There, he helped direct Soviet troops who put down the 1956 uprising by Hungarians against their Communist government. From 1957 to 1962, Andropov headed the department of the Central Committee responsible for relations between Communist-bloc countries. He became a member of the Central Committee in 1961. In 1967, he was named an alternate (nonvoting) member of the Communist Party's policy-making Politburo, as well as head of the KGB. He became a full member of the Politburo in 1973.

Herbert J. Ellison

Andros, *AN druhs,* **Sir Edmund** (1637-1714), an English administrator, served as governor of New York colony from 1674 to 1681.

In 1686, Andros became governor of the Dominion of New England, a group of English colonies. In 1687, he went to Hartford, Connecticut, to seize the charter that gave the people of that colony the right to govern themselves. They refused to surrender it. According to legend, they hid the charter in a tree, which came to be

called the Charter Oak (see Charter Oak).

The colonists of the dominion thought Andros ruled unfairly. In 1689, Boston citizens imprisoned him. He was sent to England for trial but was not tried. He returned in 1692 as governor of Virginia. Andros was born in London. Oonna J. Spindel

Anemia, *uh NEE mee uh,* is a condition in which the number of healthy red blood cells falls below normal. Red blood cells pick up oxygen in the lungs and carry it to tissues throughout the body. There, the oxygen is combined with food to release energy. In an anemic person, the blood cannot provide the tissues with enough oxygen. Thus, the person feels weak or tired. Other symptoms are dizziness, headaches, pale or cool skin, rapid heartbeat, and shortness of breath.

Anemia, which is not a disease itself, is caused by a variety of diseases and disorders. The main causes are (1) insufficient production of red blood cells, (2) loss of blood, and (3) excessive destruction of red blood cells.

Insufficient production of red blood cells. Each day, about 0.8 percent of the body's red blood cells wear out and are destroyed. If the body fails to replace these cells at the same rate, anemia results. Red blood cells are produced in the *bone marrow,* a tissue in the center of certain bones. This process requires the intake of various minerals and vitamins, and the proper functioning of certain hormones in the body.

Deficiency anemias develop if the diet lacks sufficient iron, vitamin B_{12}, or folic acid (also called folate or folacin). These nutrients are essential for the production of red blood cells. Deficiency anemias also result if the body cannot absorb these nutrients properly. For example, *pernicious anemia* occurs when vitamin B_{12} cannot be absorbed. Physicians treat deficiency anemias by adding the missing nutrient to the diet or by administering it through injections or in tablets.

Aplastic anemias occur if the bone marrow loses its ability to produce red blood cells. Some cases are due to diseases that affect the marrow, such as leukemia in its early stages. Other cases result from exposure to chemicals or radiation. Many cases have no apparent cause. Victims of aplastic anemia may receive a bone marrow transplant if they are young and if an appropriate donor is available. Chances of recovery are good if rejection of the transplant and infection do not occur. Other victims receive regular blood transfusions until their bone marrow begins to function again. In many cases, the marrow never regains function, and the victim requires a bone marrow transplant to survive.

Anemia of renal disease occurs as a result of the kidney's lost ability to produce a hormone called *erythropoietin.* This hormone stimulates bone marrow to make red blood cells. People whose kidneys have failed or have been removed, as well as some cancer and AIDS patients, suffer from this anemia. In 1989, the Food and Drug Administration approved *Epoetin alfa,* a drug that is a genetically engineered form of erythropoietin. The drug stimulates bone marrow to make red blood cells.

Loss of blood. The body responds to excessive blood loss by retaining water to replace the fluid part of the blood. As a result, the percentage of red cells in the blood decreases and anemia develops. The blood loss may occur rapidly, as from a wound, or slowly, as from a bleeding ulcer in the stomach. Treatment involves stopping the bleeding and, if necessary, providing blood transfusions.

Excessive destruction of red blood cells. Old red blood cells are destroyed in the liver and spleen by a process called *hemolysis.* If hemolysis occurs faster than the production of new red blood cells, anemia results. Such *hemolytic anemia* may be caused by inherited defects in the red blood cells, or it may be acquired.

Hereditary causes of hemolytic anemia include sickle cell anemia and thalassemia, disorders that affect the *hemoglobin* portion of red blood cells. Hemoglobin is the molecule that enables red blood cells to carry oxygen. Other hereditary defects may involve the *cell membrane*—the envelope that encloses a red blood cell—or the enzymes of the red blood cell. All of these hereditary disorders produce abnormal red blood cells, which are destroyed faster than normal.

Acquired hemolytic anemia can occur if the red blood cells are damaged by severe burns or freezing. It also sometimes follows infections. Normally, infections cause the body to produce *antibodies,* which attack the invading germs. In some cases, the body produces abnormal antibodies, called *autoantibodies,* which attack the person's own red blood cells.

Treatment of hemolytic anemia varies according to the cause and severity. Treatments may include drugs, blood transfusions, removal of the spleen, or a bone marrow transplant. Edward E. Morse

See also Blood (Red blood cells); Hodgkin, Dorothy Crowfoot; Sickle cell anemia; Thalassemia.

Anemometer, *AN uh MAHM uh tuhr,* is an instrument that measures wind speed. There are several types of anemometers. The most common type has three or four cone-shaped cups at the end of rods that are from 2 to 8 inches (5 to 20 centimeters) long. This unit rotates on a vertical spindle. The wind pressure is greater on the *concave* (inward curving) side of the cups, than on the *convex* (outward curving) side. Because of this, the wind makes the cups rotate regardless of wind direction. The faster the wind blows, the faster the cups rotate. The wind speed is measured by the number of revolutions the cups make in a given period of time. This information is often registered on a dial on the anemometer. However, it can also be transmitted by electrical means to display devices located some distance from the anemometer itself.

Anemometer

David O. Houghton

Anemone, *uh NEHM uh nee,* is any of more than 150 species of spring flowers that grow in woodlands and prairies in the United States and Canada. Their name comes from the Greek word for "wind." They are also called *windflowers.* The best-known anemone is the delicate *wood anemone,* with white blossoms. Other species grow much taller, and may be tinted with pink, purple, or blue. The *wild anemone,* or *pasqueflower,* is the

state flower of South Dakota and the provincial flower of Manitoba. See Pasqueflower.

Scientific classification. Anemones belong to the buttercup or crowfoot family, Ranunculaceae. The wood anemone is *Anemone quinquefolia.* J. Massey

Anemone, Sea. See Sea anemone.

Anesthesia, *an uhs THEE zhuh,* is the loss of sensation—particularly that of pain—in all or part of the body. Drugs called *anesthetics* are used to produce temporary anesthesia for medical purposes. Anesthesia is also produced by hypnosis and by *acupuncture*—the insertion of needles at certain points on the body. Some injuries and diseases, especially those of the nervous system, also can lead to loss of sensation.

Without anesthesia, doctors could not perform most surgical operations. Because an anesthetic makes the patient insensitive to pain, it greatly reduces the physical shock and emotional stress of the operation. The use of anesthetics gives the surgeon time to perform complicated operations safely.

General anesthesia is the loss of feeling in the entire body. It is accompanied by unconsciousness. General anesthetics are inhaled, injected, or swallowed. The blood carries them to the brain, where they block pain impulses in the nervous system. Common general anesthetics include enflurane, halothane, isoflurane, nitrous oxide (laughing gas), and thiopental (sodium pentothal).

A person under general anesthesia shows various signs that indicate the depth of unconsciousness. In deep levels of anesthesia, the patient loses such reflex actions as coughing, and heart and respiration rates slow. In surgery, the patient's reactions to the anesthetic and to the stress of the operation are monitored by the anesthetist to maintain a safe level of anesthesia.

Local anesthesia involves the loss of pain sensation in only a part of the body. The individual remains conscious. Local anesthetics may be applied to body surfaces or injected around nerves. Physicians often use them when they operate on the eyes, nose, mouth, or skin. Dentists also use local anesthetics during painful procedures. Common local anesthetics include lidocaine, procaine, and tetracaine. These drugs also may be used to treat pain associated with injuries or diseases.

One type of local anesthesia, called *regional nerve block,* involves injecting an anesthetic around large nerves. With this technique, only the pain impulses from a particular region of the body are blocked. *Spinal anesthesia* occurs when the anesthetic is injected into the fluid within the coverings of the spinal cord. *Peridural anesthesia* is caused by injecting the anesthetic into the space just outside the covering of the spinal cord. When this is done at the lower end of the spine, it is called *caudal anesthesia.* Both spinal and peridural anesthesia render the lower parts of the body insensitive to pain, but the patient remains conscious. They are commonly used during childbirth and for surgery on the legs.

History. Before the discovery of an effective anesthetic, the great pain and shock of operations severely limited the usefulness of surgery. In 1800, Humphry Davy, a British chemist, suggested that nitrous oxide be used as an anesthetic. However, no one tried this until 1844, when Horace Wells, an American dentist, used it on himself while having a tooth pulled.

In 1842, Crawford W. Long, a Georgia doctor, performed an operation after he had his patient breathe ether vapor until he was unconscious. In 1845, Long used ether for the first time in delivering a child. He did not publish the facts of his discoveries until 1849, by which time credit for the discovery of ether anesthesia had been given to W. T. G. Morton, a Boston dentist. At the recommendation of Charles T. Jackson, a Boston chemist, Morton used ether during a tooth extraction in the mid-1840's. In 1846, he administered ether during a surgical operation at Massachusetts General Hospital. In 1847 and 1848, Sir James Y. Simpson, a Scottish physician, used chloroform to ease the pain of childbirth. Queen Victoria was one of the first women to be anesthetized during childbirth. The use of local anesthetics did not begin until the mid-1880's.

During the early 1930's, medical schools began offering formal training in anesthesia. Over the following decade, the study of anesthesia and the administration of anesthetics was recognized as a separate medical specialty called *anesthesiology.* Edwin S. Munson

Anesthesiology, *AN uhs THEE zee AHL uh jee,* is a branch of medicine that deals with the administration of drugs for the relief of pain and anxiety during surgery and childbirth. Doctors in this field are called *anesthesiologists.* They administer drugs called *anesthetics.*

Before a surgical operation, an anesthesiologist supervises the preparation of the patient, recommends tests or medications, and selects the appropriate anesthetic. During surgery, the anesthesiologist uses various techniques to anesthetize all, or part, of the patient's body. The anesthesiologist carefully monitors the patient's important body functions and administers oxygen, drugs, and fluids to keep these functions normal.

Anesthesiologists also have special knowledge in obstetrics, pediatrics, internal medicine, and pain management. They frequently treat patients with lung problems and supervise intensive care units. They also teach specialized breathing therapies to other health workers. Many anesthesiologists operate pain clinics and conduct research to improve the care of patients during anesthesia and surgery. Edwin S. Munson

Aneurysm, *AN yuh rihz uhm,* is a balloonlike bulge that forms in a weakened area of the wall of an artery or vein. The most dangerous aneurysms are those that form in arteries, especially the arteries of the brain and the *aorta,* the main artery leading from the heart. Most aneurysms result from *atherosclerosis,* a disease caused by cholesterol build-up in artery walls. Other causes of aneurysms include genetic disorders or other defects present at birth.

The symptoms of an aneurysm vary with its location and size. There may be no symptoms, or pain may develop at the site of the aneurysm. Shortness of breath occurs if the aneurysm interferes with the heart's pumping ability. Some aneurysms press on nearby structures, producing a cough, hoarseness, or difficulty in swallowing. An aneurysm may worsen without the patient knowing and then suddenly rupture, causing a coma, paraly-

sis, or death. Many strokes result from the rupture of an aneurysm in an artery of the brain (see **Stroke**).

Physicians can detect aneurysms with X rays and, in many cases, can repair them surgically. Surgeons remove the diseased portion of the blood vessel. If it is a minor vessel, they tie off the loose ends. In a major artery or vein, they replace the diseased portion with a plastic tube, a fabric patch, or a piece of another blood vessel. Toby R. Engel

Angel, according to many religions, is a spiritual being created by God. The word *angel* comes from a Greek word meaning *messenger* or *one who is sent.* According to religious tradition, angels live in heaven and act as God's servants and as messengers between God and human beings. They also serve as guardians of individuals and nations. Angels traditionally are pictured as having a human body and wings. Poets and artists have portrayed angels as symbols of innocence or virtue.

Many religions have teachings about angels or similar beings. In some primitive religions, legends tell of bright, powerful spirits that appear in dreams and visions and protect people or tribes. In Hinduism and Buddhism, many major gods are accompanied by a band or court of spiritual beings.

Judaism, Christianity, and Islam developed the most elaborate doctrines about angels. These religions recognize an order of beings in which angels rank above human beings but under God. God is all-powerful, and the human is sometimes portrayed as in God's image. In some traditions, Satan and other "fallen angels" rebel against this order. According to other traditions, they fell because of their lust for women.

The concept of angels with a human body and wings began in the Hebrew Bible, or Old Testament, and in Christianity. Later tradition refers to many *archangels* (angels of high rank), including Saint Michael.

Christian doctrine regarding angels reached full development during the A.D. 1100's and 1200's, especially in the teachings of Saint Thomas Aquinas. Aquinas believed angels were necessary to fill the gap between God and human beings. He taught that countless numbers of angels existed and that they were immortal. According to Aquinas, angels knew everything except what depended on human choice and what was known only to God. The concept of angels strongly influenced *Paradise Lost* (1667), a famous epic by the English poet John Milton. *Paradise Lost* includes a version of Satan's fall and of Adam and Eve's expulsion from Paradise.

The Islamic belief in angels resembles that of Judaism and Christianity. These three faiths place angels near God and give special duties to some. J. H. Charlesworth

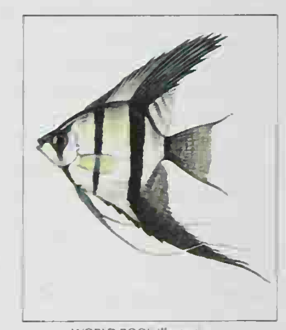
Angel Falls is the highest waterfall in the world. It drains into the Churún River in eastern Venezuela. For location, see **Venezuela** (terrain map). Angel Falls has a total height of 3,212 feet (979 meters). Its longest unbroken drop is 2,648 feet (807 meters).

Angel Falls plunges down a cliff in a highland area called *La Gran Sabana.* This region has many huge, colorful *mesas* (flat-topped hills) with sandstone surfaces. Grasslands and tropical rain forests cover much of the mesas. Some of the mesas are more than 2,500 feet (760 meters) high. There are many steep cliffs in the area. Angel Falls is located on the Auyán-Tepuí mountain, which rises 8,400 feet (2,560 meters) above sea level.



The waterfall is named for Jimmy Angel, an American pilot. Angel became the first known white person to see the falls, when he flew over it in 1935. He was searching for gold in the area. Today, small planes carry tourists over Angel Falls and its surroundings. Robert C. Eidt

See also **South America** (picture); **Waterfall** (picture).

Angelfish is the name of a type of fish that has a thin, oval body and long, pointed fins. Angelfish also have stripes or patterns on the body and patches of vivid color. There are about 75 marine species and 1 freshwater species. The freshwater angelfish is only distantly related to the marine angelfishes.

Marine angelfishes live mainly around coral reefs in warm and tropical seas. Most feed on animals or plants attached to the bottom of the reefs. Some species feed on *plankton* (tiny water organisms) in waters above the reefs. Many species are kept in commercial aquariums and are highly valued for their colorful patterns.

The freshwater angelfish is among the most popular fishes for home aquariums. It is native to the Amazon River Basin in South America. Because they are easy to breed, most freshwater angelfishes sold by aquarium shops are raised in captivity.

WORLD BOOK illustration by Colin Newman, Linden Artists Ltd

The freshwater angelfish of South America's Amazon River is popular in many home aquariums.

Scientific classification. Marine angelfish are in the family Pomacanthidae. The freshwater angelfish is in the family Cichlidae. It is *Pterophyllum scalare.* Leighton R. Taylor, Jr.

Angelico, *an JEHL uh KOH,* **Fra** (1400?-1455), was an Italian painter. He combined the clarity of form, linear perspective, and light and shade of the new Renaissance style with the flowing line, brilliant color, and symbolism of earlier medieval painting.

Fra Angelico was born in Vicchio, Italy, near Florence. He was born Guido di Pietro. He became a Dominican monk in Fiesole about 1418 and took the name Fra Giovanni da Fiesole. He was a man of legendary piety and came to be called *Fra Angelico* (angelic brother).

In 1450, Fra Angelico became prior of the Dominican convent of San Marco in Florence. Some of his most famous altarpieces, painted in the 1430's, can be seen in the museum of his work in San Marco. He and his assistants also painted the walls of the monks' cells in San Marco with religious images using a technique called *fresco.* In 1445, Fra Angelico was called to Rome where he painted in the Vatican for two popes during the next five years. He also worked in Orvieto and again in Florence before his death. His painting *The Annunciation* appears in the **Painting** article. David Summers

See also **Aquinas, Saint Thomas** (picture).

Angelou, *AN juh loh,* **Maya,** *MY uh* (1928-), is an American author, poet, playwright, editor, actress, director, and teacher. She is best known for the first installment of her autobiography, *I Know Why the Caged*

Bird Sings (1970). This work tells the story of a black girl growing up during the Great Depression. Angelou continued to chronicle her life in *Gather Together in My Name* (1974), *Singin' and Swingin' and Getting Merry Like Christmas* (1976), *The Heart of a Woman* (1981), *All God's Children Need Traveling Shoes* (1986), and *A Song Flung Up to Heaven* (2002).

Angelou's autobiographical works are realistic and exuberant. Her poetry explores issues connected to being black. *The Complete Collected Poems of Maya Angelou* was published in 1994. Several of her essays were collected in *Wouldn't Take Nothing for My Journey Now (1993)* and *Even the Stars Look Lonesome (1997).*

Angelou was born on April 4, 1928, in St. Louis, Missouri. Her given name was Marguerite Johnson. Angelou was her first husband's family name. Nellie Y. McKay

Angina pectoris, *an JY nuh PEHK tuhr ihs,* is chest discomfort or pain that occurs when the blood flow to the heart is limited. The word *angina* means *to strangle,* and angina pectoris feels like a pressing or squeezing sensation in the area of the breastbone. The pain may travel to the shoulders, especially the left shoulder, and down the arms. The pain is usually called simply *angina.*

An attack of angina can occur any time the heart works harder than usual and requires an additional supply of blood. For example, an attack may occur following physical exertion or during a time of emotional stress. Blood flowing through the coronary arteries carries oxygen to the heart. The coronary arteries can become narrowed by accumulations of fatty deposits, called *plaque,* and scar tissue. These conditions result in *arteriosclerosis* (hardening of the arteries), a disease that is the primary cause of angina pectoris. If the coronary arteries are narrowed, extra blood cannot reach the heart. Part of the heart muscle is temporarily deprived of oxygen carried by the blood, causing pain. Angina can also be caused by a spasm in the coronary artery.

Monastery of San Marco, Florence, Italy (SCALA/Art Resource)

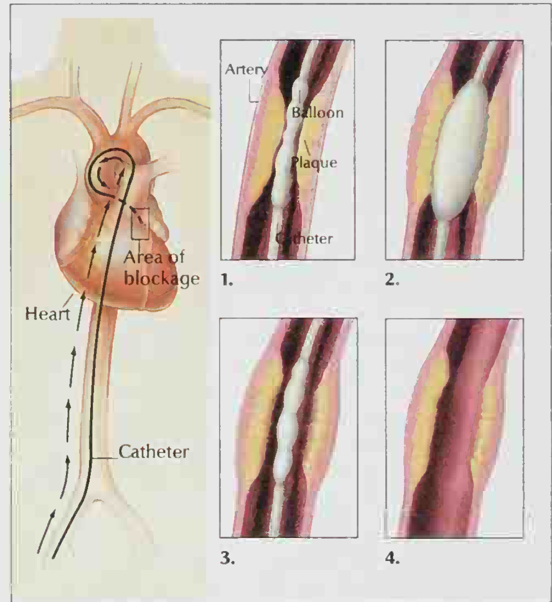
***Annunciation* by Fra Angelico** shows the Italian artist's skill in combining delicate colors with simple, graceful figures.

Most people who experience angina are commonly middle-aged or older. Many are overweight, have high blood pressure, eat foods high in cholesterol, smoke cigarettes, and get little exercise. Resting and taking a medication called *nitroglycerin* can relieve most attacks of angina. Doctors may also prescribe drugs called *beta-blockers* and *calcium channel blockers.* These drugs help keep the heart from working harder under stress.

When medication can no longer control angina, other treatments are necessary. Physicians may perform a procedure called *angioplasty* to clear the narrowed arteries. Angioplasty involves threading a balloon-tipped *catheter* (slender tube) into the blocked artery. The balloon is then inflated, flattening the blockage against the artery wall. In severe cases of angina, narrowed coronary arteries may be by-passed by grafts of vessels taken from the leg or chest. Surgeons may use lasers to create channels in the heart muscle to increase blood flow. Scientists are also investigating ways to increase blood flow to the heart by stimulating *angiogenesis*—that is, the growth of new blood vessels. James W. Jones

See also **Calcium channel blocker; Heart** (Coronary artery disease); **Nitroglycerin** (As a medication).

Angiography, *AN jee AHG ruh fee,* is a technique that makes blood vessels visible using X rays. The X-ray picture that is produced is called an *angiogram.* Angiography is usually performed on arteries or veins connected with such structures as the brain, heart, kidneys, or legs.



Angiography is used to decide whether a narrowing of a blood vessel is being caused by a clot or by deposits of such substances as cholesterol and calcium. Such deposits are called *plaques.* Physicians also use angiography to decide possible therapies. For example, coronary angiography is often performed on patients whose coronary arteries have narrowed. This procedure can help a physician determine whether medication, surgery, or such techniques as *angioplasty* would be the best way to treat the condition (see **Angioplasty**).

During a typical angiographic procedure, a *catheter* (long tube) is passed through the skin and inserted into a vein or artery, usually in an arm or leg. The catheter is advanced to the structure being evaluated, and special *contrast material,* often containing iodine, is injected into the area. This material makes the area being examined stand out from its background when an X ray is taken. Julius M. Gardin

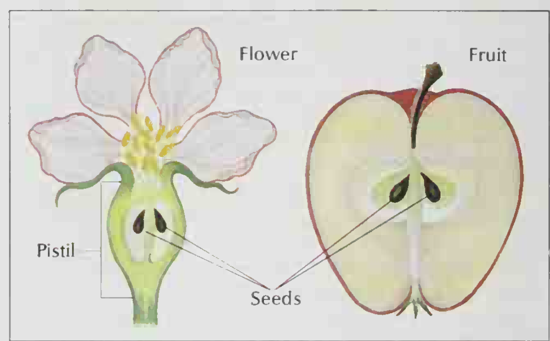
See also **Stress test.**

Angioplasty, *AN jee oh PLAS tee,* is a technique used to open arteries that have become blocked by deposits of cholesterol, calcium, and other substances. Such deposits are called *plaques.* Angioplasty is especially important for patients whose coronary arteries have become critically narrowed and who have *angina* (chest pain that occurs during exertion) or a high risk of heart attack. Angioplasty provides an alternative to surgery.

In coronary angioplasty, a *catheter* (long tube) with a balloon attached to it is inserted into the blocked artery. After the catheter enters the narrowed part of the vessel,

WORLD BOOK illustrations by Charles Wellek and Tom Rolain

In coronary angioplasty, surgeons insert a long tube called a *catheter* through the patient's groin and guide the catheter to a blocked artery in the heart. The close-ups show the interior of the artery during the procedure. A balloon on the catheter is positioned in the artery (1) and inflated (2) to crush deposits called *plaques* and expand the artery. The balloon is then deflated (3) and removed, leaving the inside diameter of the artery wider (4).



the balloon is inflated. The balloon then pushes the plaque against the artery wall and expands the artery. In most cases, slight injury to the wall of the artery accompanies the widening of the vessel's inside diameter. This damage may benefit the patient, however, because further widening can occur as the artery wall heals.

Most angioplasties are successful. In about 30 percent of patients, however, the cleared vessel soon renarrows, requiring another angioplasty or surgery. In a small number of cases, the procedure severely tears the artery. In those cases, the patient must undergo immediate surgery and repair. Doctors have prevented tears and abrupt closures of arteries by inserting an expandable metal mesh called a *stent* into the vessel. The stent prevents collapse of the artery wall without blocking blood flow. In some cases, a stent can also reduce the chance that the artery will renarrow.

Michael H. Crawford

Angiosperm, *AN jee uh spurm,* is the technical name for flowering plants. Angiosperms make up the vast majority of all plant *species* (kinds). They also occur in many of the world's environments, including Arctic tundra, deserts, and rain forests. Among the most important angiosperms are broadleaf trees and crop plants.

Angiosperm flowers contain both male reproductive organs called *stamens* and female reproductive organs called *pistils.* Stamens produce pollen grains that carry *sperm* (male sex cells) to the pistils. Pistils contain *ovules,* or eggs, that become seeds after fertilization by sperm. The pistils develop into fruits, which take a variety of forms. Berries, for example, are soft and fleshy, while nuts are hard and dry.

WORLD BOOK illustration by Lorraine Moseley Epstein

The flower and fruit of an angiosperm contain the plant's seeds. The seeds develop in the flower's pistil, which grows into the fruit. The flower and fruit of an apple tree are shown here.

About three-fourths of all angiosperms are *dicotyledons,* or *dicots.* Young dicot seedlings bear two tiny leaves called *cotyledons.* The remaining angiosperm species, the *monocotyledons* or *monocots,* have seedlings with one cotyledon. The other major group of seed plants, collectively called *gymnosperms,* do not bear flowers or possess pistils. The most common gymnosperms are pines and other needleleaf trees.

Bruce H. Tiffney

Scientific classification. Angiosperms make up the class Anthopsida within the division Tracheophyta.

See also Flower; Gymnosperm; Seed.

Angkor, *ANG kohr,* was an early civilization that flourished in northwestern Cambodia from the early 800's to the 1400's. The most famous capital of this civilization was also called Angkor. Ruins of its temples lie near the present-day city of Siem Reap (see Cambodia [map]).

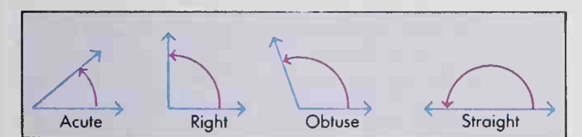
Cambodian kings built several cities in the vicinity of Siem Reap between 820 and the 1100's. The city of Angkor was the most magnificent. It may have had a million people, more than any European city at that time. The city included Angkor Thom, which was actually a city within the city of Angkor, and covered 4 square miles (10 square kilometers). The city of Angkor also contained many temples and palaces. The city and its temples rank as one of the artistic and architectural wonders of the world. Carved scenes of Cambodian life and Buddhist or Hindu mythology decorate the walls of the temples.

One of the temples, Angkor Wat, is probably the finest architectural monument in Cambodia. It covers nearly 1 square mile (2.6 square kilometers) and has a pyramidal form. This form imitates the mythological home of the Hindu gods. Angkor Wat was constructed in the 1100's to honor the Hindu god Vishnu. It was also used as an astronomical observatory. Angkor Wat later became the tomb of the Cambodian king who had ordered its construction. Another temple, the Bayon, stands at the center of Angkor Thom. It was dedicated to Buddha and the reigning king. More than 200 giant stone faces adorn its towers.

The civilization of Angkor reached its peak during the 1100's and then began to decline. Invasions from neighboring Thailand, epidemics of malaria, and disputes within the royal Cambodian family may have caused this decline. Thai forces captured the city of Angkor in 1431 but soon abandoned it, and forest growth gradually

covered most of the city. In 1860, Henri Mouhot, a French naturalist, discovered the city's ruins. From the 1860's to the mid-1900's, French and Cambodian archaeologists restored and rebuilt many of its temples.

David P. Chandler



See also **Architecture** (picture: Angkor Wat).

Angle, in plane geometry, is a figure formed by two *rays* with the same end point. A ray is a part of a line extending indefinitely in one direction from a point. The point where the rays of an angle meet is called the *vertex,* and the rays themselves are known as the *sides.*

The size of an angle is usually measured in *degrees.* When the rays make a square corner, the angle is a *right angle.* A right angle has 90 degrees (90°). An *acute angle* has less than 90°. An *obtuse angle* has between 90° and 180°. An angle of 180° is a *straight angle* because its sides form a straight line. Two angles are *complementary* if their sum is 90°. They are *supplementary* if their sum is 180°. People use a simple device called a *protractor* to measure angles.

In trigonometry, an angle is considered to consist of a fixed, or *initial,* side and a rotating, or *terminal,* side. The amount and direction of rotation of the terminal side determine the size of the angle and whether it is *positive* or *negative.* Positive angles are formed when the rotation of the terminal side is counterclockwise. Negative angles are formed when the rotation is clockwise. If one hand of a clock is fixed at 3 and the other hand starts at 3 and turns counterclockwise until it reaches 12, an angle of 90° results. This rotation is known as a *quarter turn.* A *half turn* results in an angle of 180°; a *three-quarter turn,* in an angle of 270°; and a *full turn,* in an angle of 360°. A second complete rotation of the terminal side generates angles between 360° and 720°, a third rotation produces angles between 720° and 1,080°, and so forth for all positive angles.

Kinds of angles

Negative angles are formed when the terminal side moves clockwise. Compass directions in naval navigation are given by means of angles measured in the clockwise direction from 12. But, the measurements are given in positive numbers. Arthur F. Coxford, Jr.

Angle of incidence. See **Reflection.**

Angler, a fish. See **Fish** (How fish get food; picture: A fleshy bait).

Angles made up one of the Germanic peoples who invaded Britain during the A.D. 400's and 500's. The best known of the other invaders were the Saxons and Jutes, to whom the Angles were closely related. The invaders established small kingdoms, some of which lasted until the Norman Conquest in 1066. See **Anglo-Saxons.**

The Angles came from Angeln, a district in what is now Schleswig-Holstein, and from the southern part of the Danish peninsula. They conquered the Britons who lived along the east coast, and founded the kingdoms of Northumbria, Mercia, and East Anglia in what is now north, central, and east England. The name *England* came from an Anglo-Saxon word that meant *Angle folk* or *land of the Angles.* John Gillingham

See also **England** (History).

Angleworm. See **Earthworm.**

Anglicans, *ANG gluh kuhnz,* are Christians who belong to churches that are part of the Anglican Communion. These churches developed from the Church of England. In addition to the Church of England, the major churches in the Anglican Communion include the Anglican Church of Canada and the Episcopal Church in the United States. See **Church of England; Episcopal Church.**

The Anglican heritage dates back to the earliest days of Christianity in Anglo-Saxon England. During the Reformation of the 1500's, the Church of England separated from the Roman Catholic Church. Anglicanism spread as British colonists settled in North and South America, Australia, New Zealand, Africa, and Asia. See **Reformation** (In England).

Doctrines. Anglicans believe in the ancient faith of the Christian church as expressed in the Apostles' and Nicene creeds (see **Apostles' Creed; Nicene Councils**). Anglicans base their religion on scripture, tradition, and reason. All Anglicans follow the Book of Common Prayer, which is the basis for doctrine and discipline as well as worship. But they acknowledge the right of national churches to revise the Book of Common Prayer according to their needs.

Organization. Anglican clergy consist of bishops, priests, and deacons. However, lay people took an increasingly important part in church affairs in the 1900's. The unity of the Anglican Communion is symbolized by the Lambeth Conference of bishops, which meets about every 10 years in London. The Conference can only advise the churches it represents. It is mainly a consulting and planning body. The Archbishop of Canterbury ranks as the senior bishop but has no formal power outside of England. Since 1960, the Anglican Communion has employed an executive officer who attends to matters concerning the entire Communion.

Christian unity. Under the leadership of such bishops as Charles Henry Brent, William Temple, Geoffrey Francis Fisher, and A. M. Ramsey, the Anglicans have become deeply involved in promoting the unification of Christianity. Each church of the Communion belongs to the World Council of Churches and works closely with the Church of Sweden, Eastern Orthodox Churches, and Old Catholic Churches. Talks between Anglicans and representatives of the Roman Catholic Church began in the 1960's.

Anglicans seek unity because they believe that most Christians follow the Bible, the Apostles' and Nicene creeds, the sacraments of the Eucharist and Baptism, and the historic forms of ministry. Anglicans in several dioceses in India showed this desire for unity in 1947 by entering the new Church of South India, along with the Methodist, Presbyterian, and Congregational mission churches there.

Episcopalians. Anglicans first settled in America as members of the first permanent English colony in Virginia in 1607. In 1789, after the Revolutionary War, Anglicans in the colonies separated from the Church of Eng-

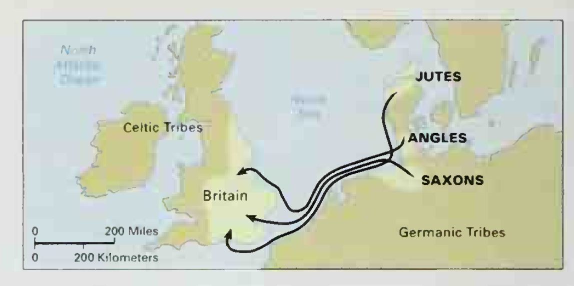
land and formed the Protestant Episcopal Church. This church's first bishops were Samuel Seabury of Connecticut, William White of Pennsylvania, and Samuel Provoost of New York. From that time, the Episcopal Church moved westward and spread throughout the United States.

Episcopalians differ on how to interpret and practice their Christian faith. *High Churchmen* believe in following closely the traditional practices and the authority of the church and often have elaborate worship services. *Broad Churchmen,* or *Liberals,* care less for tradition, and believe in expressing their faith in various ways, particularly through social action. *Low Churchmen,* or *Evangelicals,* emphasize the personal and Biblical bases of faith. Episcopalians today differ over issues such as the revision of the Book of Common Prayer and the ordination of women as priests and bishops. But they are united in their common worship and sense of tradition.

Peter W. Williams

Anglo-Saxon Chronicle, *ANG gloh SAK suhn,* is the first great work of English prose and the most important source for English history from about 800 to 1066. No other European land has a history in its own language as old as the *Chronicle.*

The *Chronicle* was begun as part of a cultural renewal by King Alfred the Great following destructive raids by Danish invaders. The first part of the *Chronicle,* dealing with events up to 891, was adapted from earlier English historical sources, now lost. After about 892, a number of writers contributed to the *Chronicle* in copies circulated among several English cathedrals.



The *Chronicle* consists of short yearly descriptions of major events, especially warfare, and the activities of kings and bishops. Many entries consist of only one line. The longest entry runs more than 100 lines and deals with the death of William the Conqueror in 1087. Many years have no entries. The earliest important entry in the *Chronicle* refers to events in A.D. 449. The final one was made in 1154. David S. Chamberlain

See also Alfred the Great.

Anglo-Saxons, *ANG gloh SAK suhnz,* were members of the Germanic tribes that settled in what is now England in the A.D. 400's and 500's. These tribes were the Angles, the Saxons, and the Jutes. According to tradition, a British king named Vortigern invited the Germanic tribes to help him drive back the invading Picts and Scots. But the allies quarreled, and soon the Germanic tribes began to drive out the native Britons. By the end of the 500's, the Angles, Saxons, and Jutes had occupied nearly all of southern and eastern Britain.

At first there were many Anglo-Saxon kingdoms, and wars between them were frequent. By the 700's, there were only seven kingdoms: East Anglia, Essex, Kent, Mercia, Northumbria, Sussex, and Wessex. Together, they were known as the *heptarchy,* which means *rule of seven.* In the early 800's, Egbert of Wessex became the first king to establish control over the entire heptarchy.

In the late 800's, all the kingdoms came under attack from Danish Vikings. Only Wessex, under Alfred the Great, survived the invasion. Alfred eventually captured London and other areas. In the 900's, Alfred's descendants defeated the Vikings and incorporated the Viking territory into their kingdom. This new and larger kingdom was called *England,* a word that came from Anglo-Saxon words meaning *Angle folk* or *land of the Angles.*

WORLD BOOK maps

The seafaring Jutes, Angles, and Saxons who invaded Britain in the A.D. 400's, *smaller map,* became known as Anglo-Saxons. They formed seven kingdoms, *larger map.*

The Anglo-Saxons left their mark on the English language in its grammar and in thousands of words, including perhaps a fifth of the words we use today.

John Gilling

Angola is a country on Africa's southwest coast. Its official name is the Republic of Angola. Cabinda, in the northwest, is a district of Angola. The Congo River and Congo (Kinshasa) separate it from the rest of the country.

Most of Angola's people live in rural areas and work on farms. Angola produces a variety of crops, including bananas, coffee, corn, sugar cane, and a starchy root called *cassava.* Angola also has many natural resources, including diamonds, iron ore, and petroleum. Luanda, the capital and largest city, is a major African seaport.

Angola became independent in November 1975. Parts of it had been ruled by Portugal for most of the period

since the 1500's. Since 1975, Angola has been torn apart by a brutal civil war. But a cease-fire was signed in 2002.

Government. A president is the most powerful official in Angola's government. The National Assembly, the country's legislature, makes the laws. The people of Angola elect both the president and the National Assembly. The party with the majority of seats in the National Assembly chooses a prime minister to help run the day-to-day affairs of the government.

People. Most of Angola's people are black Africans. They belong to several ethnic groups, including the Ovimbundu, the Mbundu, the Kongo, and the Luanda-Chokwe. Before the nation became independent, more than 400,000 Europeans and *mestizos* (people of mixed black African and white ancestry) lived in Angola. Most Europeans fled during the civil war that began in 1975.

People in Angola's rural areas work as farmers and herders. Many raise just enough food for their own use. Most Europeans and mestizos who did not leave the country live in cities. They own small businesses or hold other jobs that require technical and management skills.

Most black Angolans speak a language that belongs to the Bantu language group (see **Bantu**). Europeans, mestizos, and some blacks speak Portuguese, the official language. About 90 percent of the people are Christians, mostly Roman Catholics. Others practice religions based on the worship of ancestors and spirits. Most of Angola's adults cannot read or write. For the country's literacy rate, see **Literacy** (table: Literacy rates).

Land and climate. Angola forms part of the large inland plateau of southern Africa. The country consists chiefly of hilly grasslands, but a rocky desert covers the south. The land gradually rises from the interior to the west, where it drops sharply to a narrow coastal plain. Most of the coastal plain has little natural vegetation. Tropical forests grow in the north.

Angola has many rivers and more than 900 miles (1,400 kilometers) of coastline. Some of the rivers flow north into the Congo River, and others flow west into the Atlantic Ocean. A few, including the Cunene and the Cuanza, serve as waterways to the interior.

Temperatures in the coastal plain region average about 70 °F (21 °C) in January and about 60 °F (16 °C) in June. Most of the inland region has slightly higher temperatures. From 40 to 60 inches (100 to 150 centimeters) of rain falls annually on the northern coast and in most of the interior. Only about 2 inches (5 centimeters) of rain falls yearly in the desert.

Economy of Angola is based on agriculture. But mining and manufacturing have become more important. The main food crops include bananas, cassava, corn, and sugar cane. Angola produces coffee for export. Fishing is important in coastal areas. Angola has vast deposits of diamonds, iron ore, and petroleum. Diamonds are a major source of income for both the government and rebel groups. Cabinda provides most of the petroleum, the leading export. Angolan industries produce cement, chemicals, processed foods, and textiles.

Most of Angola's roads are unpaved. An extensive railroad system serves many Angolan cities. The system also provides neighboring Zambia and Congo (Kinshasa) with an important link to the sea. Luanda has an international airport. Angola has one daily newspaper.

History. Prehistoric peoples lived in what is now Angola as early as 50,000 B.C. Bantu-speaking peoples settled there about 2,000 years ago. The Portuguese established bases in Angola during the 1500's. By the early 1600's, Angola had become a major source of slave labor for Portugal's colony in Brazil. In 1641, the Dutch forced the Portuguese out of Angola and took over the slave trade. Portugal regained control in 1648. During the 1800's, after the decline of the slave trade, Portuguese planters began to grow corn, sugar cane, and tobacco in Angola. Angola was sometimes called Portuguese West Africa during Portuguese rule.

Portugal began to improve Angola's economy after the Portuguese dictator António de Oliveira Salazar came to power in the late 1920's. Thousands of Portuguese moved to Angola and started businesses there.

In the 1950's, many Angolans began to demand freedom from Portuguese rule. In 1956, the Popular Movement for the Liberation of Angola (MPLA) was organized. MPLA members revolted in Luanda in 1961. Rioting spread throughout the country and developed into a bloody war. A Portuguese army that included many An-

Facts in brief

Capital: Luanda.
Official language: Portuguese.
Area: 481,354 mi² (1,246,700 km²). *Greatest distances*—north-south, 850 mi (1,368 km); east-west, 800 mi (1,287 km). *Coastline*—928 mi (1,493 km).
Elevation: *Highest*—Môco, 8,596 ft (2,620 m). *Lowest*—sea level.
Population: *Estimated 2002 population*—13,684,000; density, 28 per mi² (11 per km²); distribution, 68 percent rural, 32 percent urban. *1970 census*—5,646,166.
Chief products: *Agriculture*—bananas, cassava, coffee, corn, sugar cane. *Manufacturing*—food processing, cement, chemicals, textiles. *Mining*—diamonds, petroleum.
Flag: The top half is red, and the bottom half is black. A yellow emblem in the center has a five-pointed star that stands for socialism, a half cogwheel for industry, and a machete for agriculture. Adopted in 1975. See **Flag** (picture: Flags of Africa).
Money: *Basic unit*—new kwanza.

Hutchison Library

An Angolan village lies in the rocky desert terrain of the southern part of the country. About two-thirds of Angola's people live in rural areas and work as farmers and herders.

golans put down the uprising. The MPLA rebels then set up guerrilla bases in neighboring countries.

Cultural and political differences soon divided the rebels. In 1962, a group of northern rebels formed the National Front for the Liberation of Angola (FNLA). In 1966, southern rebels organized the National Union for the Total Independence of Angola (UNITA). In 1974, Portuguese military officers overthrew the government of Portugal. In January 1975, they decided to grant independence to Angola. At first, the Angolans agreed to set up a government with representatives from all three rebel groups. But each group wanted to head the government. A civil war broke out over which would rule.

Angola gained independence from Portugal on Nov. 11, 1975. But the civil war continued between the MPLA and the FNLA and UNITA, whose forces had united. The MPLA received considerable aid from two Communist nations, the Soviet Union and Cuba. The United States and South Africa assisted UNITA. The MPLA largely defeated its enemies in April 1976 and formed a *Marxist government* (government based on the philosophy of Karl Marx). But MPLA leaders denied the government was a Communist dictatorship.

Angola's new government faced major problems. Members of UNITA continued to wage guerrilla warfare against the government. The FNLA also carried out guerrilla activities until 1984, when it became inactive. The sudden departure of most of Angola's Europeans caused a shortage of executives and technicians. Many industries and large farms could not be managed properly, and production declined.

The government began several programs to overcome the effects of the civil war. It took control of many businesses and started to train teachers and technicians. The Soviet Union, Cuba, and other Communist countries provided financial and technical aid. But the government also encouraged non-Communist nations to invest in Angolan businesses. Cuba kept troops in Angola to aid the government in its fight against the guerrillas.

Under an agreement signed by Angola, Cuba, and South Africa in late 1988, South Africa stopped sending aid to UNITA, and Cuba began withdrawing its troops. In 1989, the government and UNITA agreed to a cease-fire. The two sides signed a peace treaty in May 1991. Violence continued in the Cabinda area, where guerrillas demanded Cabinda's independence from Angola.

In 1990, the MPLA renounced Marxism, and in 1991, legalized all political parties. Multiparty elections were held in September 1992. The head of the MPLA government, José Eduardo dos Santos, won the first round of the elections. But UNITA protested that the elections were fraudulent, and civil war erupted again. The second round of the elections did not take place, but dos Santos continued as president.

The two sides signed a peace agreement in November 1994. However, in 1998 and early 1999, violence increased, and the peace agreement broke down. The fighting continued, mainly in northwestern Angola. In February 2002, government troops shot and killed UNITA's longtime leader, Jonas Savimbi. In April, the two sides signed a cease-fire agreement. Louis A. Picard

WORLD BOOK maps

Angora, *ang GAWR uh,* is a hair fiber made from the fur of the Angora rabbit. The term is sometimes used for hair fiber made from the Angora goat, but the goat fiber

is correctly called *mohair.* Both animals are native to the Turkish province of Ankara (formerly Angora). Pure angora is used to make soft fabrics. It is usually blended with other fibers and then spun into yarn. Angora is also the name of a type of cat. See also **Cat** (Long-haired breeds); **Mohair; Rabbit** (picture). Keith Slater

Angstrom, *ANG struhm,* is a unit of length used to measure very small distances. For example, the atoms in a salt crystal are only several angstroms apart. Wavelengths of light are sometimes measured in angstroms. The wavelength of visible light measures several thousand angstroms. One angstrom equals $\frac{1}{10}$ nanometer, or $\frac{1}{10,000,000}$ millimeter ($\frac{1}{254,000,000}$ inch). The angstrom is abbreviated A or Å. It is named in honor of the Swedish physicist Anders Jonas Ångström, who made important studies of light. Lawrence P. Brehm

Anguilla, *ang GWIHL uh,* is a coral island in the Caribbean Sea. It is an overseas territory of the United Kingdom. Anguilla covers about 37 square miles (96 square kilometers) and has a population of about 11,000 (see **West Indies** [map]). It has a dry, hot climate and is covered by low-lying plant life. Tourism has replaced fishing and salt processing as Anguilla's major industry. A community called The Valley is the island's capital.

Christopher Columbus may have sighted the island in 1493 during his second voyage to the New World. Explorers named the island *Anguilla* (Latin for *eel*) because of its long, narrow shape. It became a colony of Britain in 1650. In 1883, Britain made Anguilla and the Caribbean islands of St. Christopher (now called St. Kitts) and Nevis a single colony. It became an associated state of Britain in 1967. But most Anguillans favored separation from St. Kitts and Nevis. In 1980, Anguilla officially became a separate British dependency (see **West Indies** [History]). Gerald R. Showalter

Anhinga, *an HIHNG guh,* also called *American darter,* is a large bird that lives in swamps, ponds, and rivers in warm regions of the Western Hemisphere. It is found from the south-central and southeastern United States to Argentina. The anhinga measures about 3 feet (91 centimeters) in length, with a long, thin neck; a small head and pointed bill; and webbed feet. It has glossy black feathers, with silver markings on the back of the wings and neck, and a broad, brown-tipped tail. The anhinga feeds on fish and other water animals, which it spears with its bill. It is an excellent swimmer and a strong flier. The anhinga is sometimes called the *snakebird* because it often swims with only its head and snakelike neck visible above the surface.

The Old World darters, which resemble the anhinga, live in tropical and subtropical regions of Africa, Asia, New Guinea, and Australia. Most experts recognize three species of Old World darters, the *African, Oriental,* and *Australian darters.* James J. Dinsmore

Scientific classification. Anhingas and darters make up the anhinga family, Anhingidae. The anhinga is classified as *Anhinga anhinga.* The African darter is classified as *A. rufa;* the Oriental darter as *A. melanogaster;* and the Australian darter as *A. novaehollandiae.*

See also **Bird** (picture: How birds feed).

Anhydride, *an HY dryd,* is a chemical substance that forms acids or bases when combined with water. For example, water and sulfur trioxide (SO_3), an acid anhydride, make sulfuric acid (H_2SO_4). Water and calcium oxide (CaO), a basic anhydride, make basic calcium hydroxide ($Ca(OH)_2$). Anhydrides can be formed by dehydrating acids and bases, or by synthesis directly from other substances. Anhydrides are used in the manufacture of artificial fibers, plastics, photographic films, and medicines. See also **Acid; Base.** Roger D. Barry

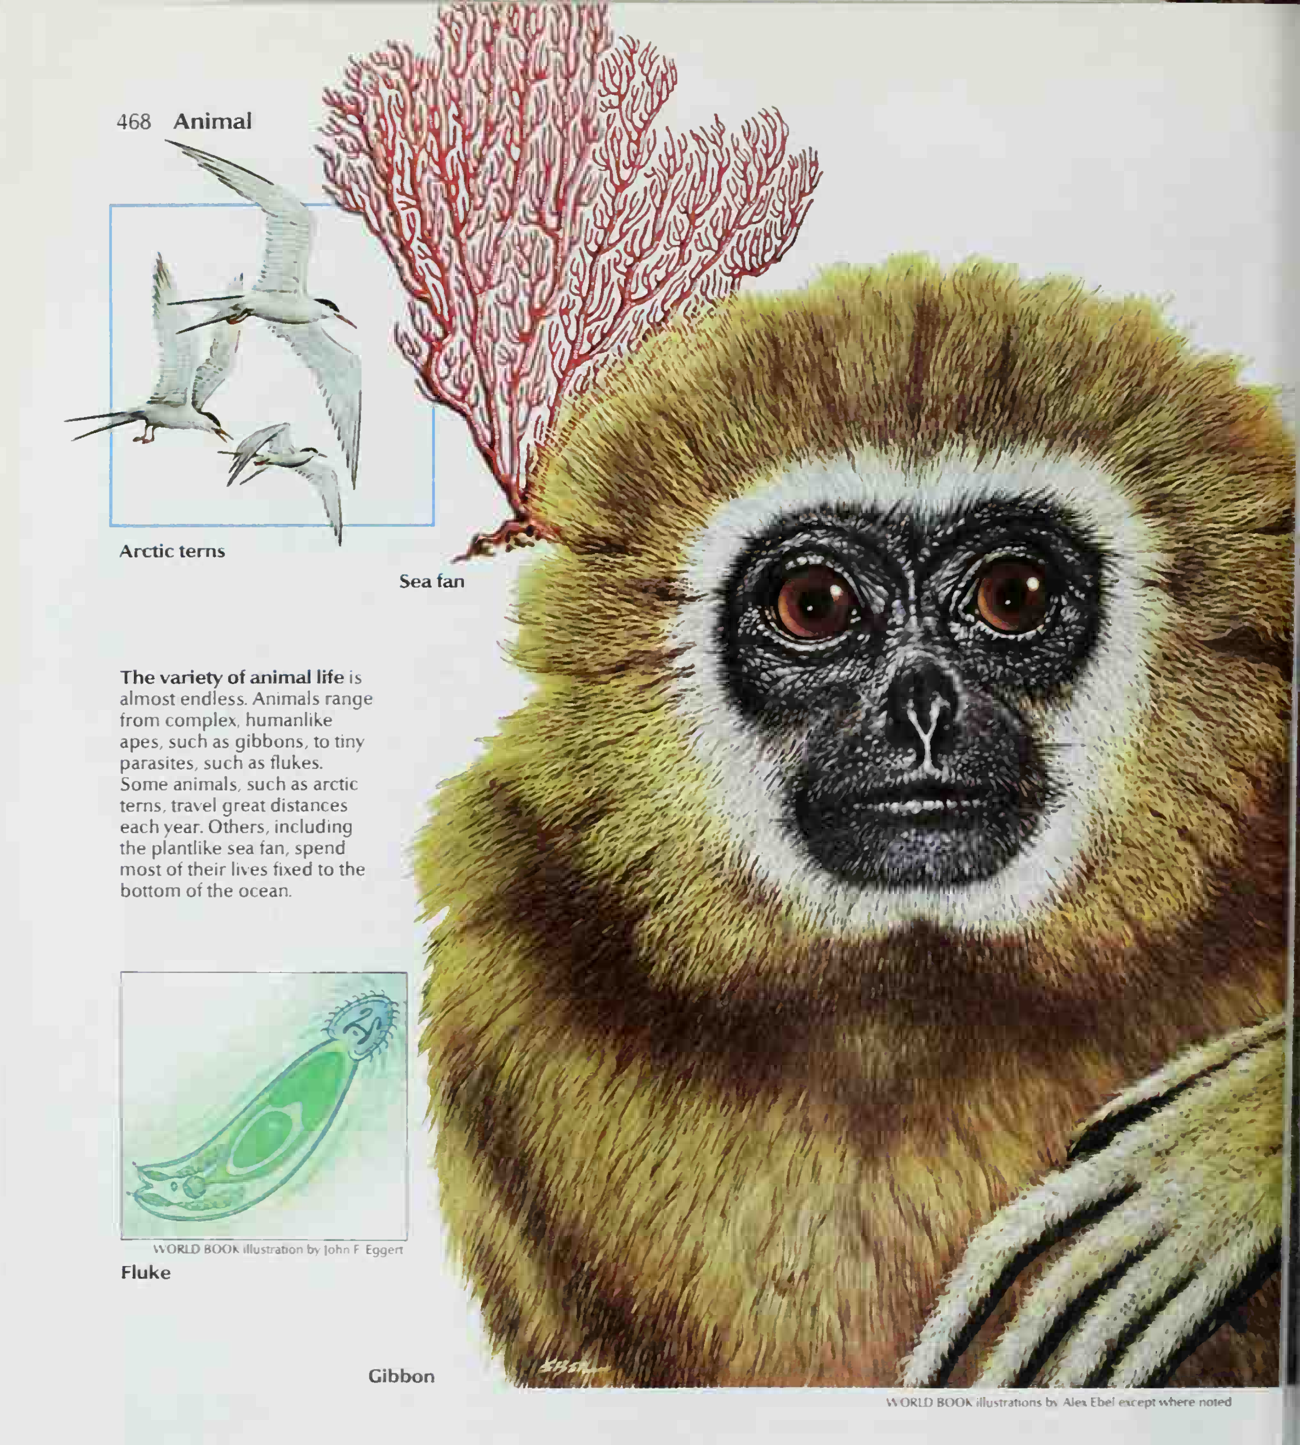
Anhydrous ammonia, *an HY druhs uh MOHN yuh,* is the liquid form of pure ammonia gas. Because of its high nitrogen content—about 82 percent—farmers use anhydrous ammonia as a fertilizer. It may be used alone or in a commercial mixture containing compounds of phosphorus and potassium. It may be combined with water to form a solution for making a mixed fertilizer. Anhydrous ammonia is also used as a refrigerant in cold-storage and ice-manufacturing plants. It is made by compressing dry ammonia gas (NH_3). See also **Ammonia; Ice; Refrigeration.** Taylor J. Johnston

Ani, *AH nee,* is the name of three species of birds in the cuckoo family. Anis live in open, brushy country, mainly from the West Indies and Mexico to southern South America. Two of the species are also found in the extreme southern United States. The *smooth-billed ani* nests in southern Florida, and the *groove-billed ani* lives in southern Texas. The third species, the *greater ani,* ranges only as far north as central Panama.

Anis measure from 12 to 15 inches (30 to 40 centimeters) in length, about half of which is tail. They have a huge bill with a high arched ridge and black feathers that shine with a purple, green, or bronze luster. Anis feed chiefly on insects. They often gather in pastures where cattle are grazing. There, they seize large ground-dwelling insects that are stirred up by the cattle. Anis sometimes perch on the cattle's backs.

Anis live in noisy flocks of up to about 20 birds. Each flock consists of one to four mated pairs and a number of younger, unmated birds. During the breeding season, the flock claims a territory and prevents other anis from entering it. All of the birds in the flock build a single nest of twigs in a tree or thorny bush. Each mated female lays three to five eggs in the nest. The entire flock helps care for the eggs and the young. Sandra L. Vehrencamp

Scientific classification. Anis belong to the cuckoo family, Cuculidae. The scientific name for the smooth-billed ani is *Crotophaga ani.* The groove-billed ani is *C. sulcirostris,* and the greater ani is *C. major.*



Aniline, *AN uh lihn,* is a chemical best known for its use in making dyes. Aniline became important in 1856, when the British chemist William Perkin accidentally made a violet dye from aniline.

Industries use aniline dyes to color textiles and in making inks, paints, and varnishes. Bacteriologists use the dyes to stain bacteria and other organisms. Industries also use aniline in making drugs, explosives, rocket fuels, and other products.

In the laboratory, chemists prepare aniline through a chemical reaction involving nitrobenzene, iron filings, and hydrochloric acid. In industry, aniline is prepared by heating chlorobenzene and ammonia under high pressure, or by a process using nitrobenzene

Aniline is a colorless, oily liquid that is only slightly soluble in water. It has a strong, pleasing odor but is highly poisonous. Aniline boils at 184 °C. Its chemical formula is $C_6H_5NH_2$. Howard L. Needles

The variety of animal life is almost endless. Animals range from complex, humanlike apes, such as gibbons, to tiny parasites, such as flukes. Some animals, such as arctic terns, travel great distances each year. Others, including the plantlike sea fan, spend most of their lives fixed to the bottom of the ocean.

WORLD BOOK illustration by John F. Eggert

WORLD BOOK illustrations by Alex Ebel except where noted

Animal

Animal. Animals come in many shapes and sizes. They live throughout the world. Animals walk or crawl on land and dig through the soil. They swim in the water and fly through the air. They even live inside the bodies of other animals. Bats, dogs, horses, kangaroos, and moles are all animals. So are butterflies, frogs, jellyfish, pigeons, sharks, snakes, and worms.

Most kinds of animals are less than 1 inch (2.5 centimeters) long. Many are so tiny that they can be seen only with a microscope. The largest animal is the blue whale. It is about as long as five elephants in a row.

Animals are not the only kind of living things. Scientists divide living things into five main *kingdoms* (groups)—animals, plants, fungi, protists, and prokaryotes. *Fungi* include molds, mushrooms, and yeasts. *Protists,* such as amebas, cannot be seen without a microscope. *Prokaryotes,* which include bacteria and certain algae, are some of the smallest, simplest forms of life.

The contributors of this article are Raymond B. Huey, Professor of Zoology at the University of Washington, and W. Herbert Wilson, Jr., Assistant Professor of Biology at Colby College.

Interesting facts about animals

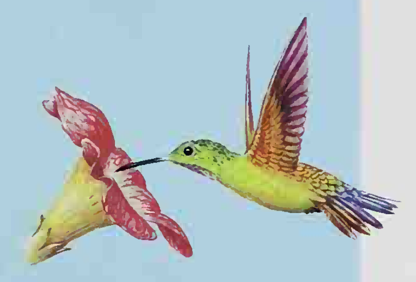
Kinds of animals. No one knows exactly how many kinds of animals there are. New kinds are found every year. So far, scientists have identified more than 1 ½ million types of animals. About 1 million of these are insects. There are about 21,000 kinds of fish, 9,700 kinds of birds, 6,500 kinds of reptiles, 4,000 kinds of amphibians, and 4,500 kinds of mammals.

Largest ears and eyes. The largest ears of all animals are those of the African elephant. Elephant ears grow as large as 4 feet (1.2 meters) across. The largest eyes of all animals are those of the giant squid. They measure about 10 inches (25 centimeters) wide.

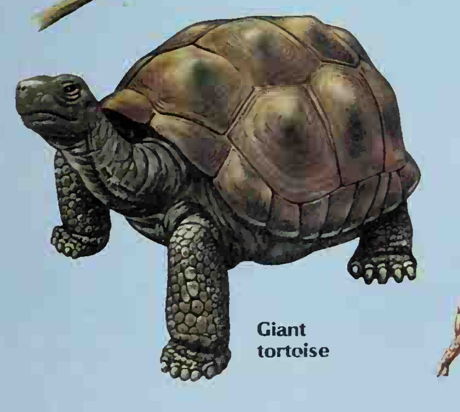
Elephant

Blue whale

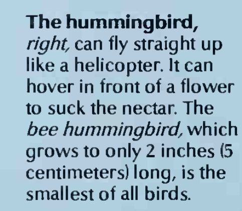
Giraffe



The flying dragon is another name for the draco lizard. This lizard can spread out folds of skin to form "wings" that it uses to glide through the air from tree to tree. It lives in Asia and the East Indies.



The huge blue whale is far bigger than the elephant, the biggest land animal, or the giraffe, tallest of all the animals.



Mayfly

The hummingbird, *right,* can fly straight up like a helicopter. It can hover in front of a flower to suck the nectar. The *bee hummingbird,* which grows to only 2 inches (5 centimeters) long, is the smallest of all birds.

The chameleon's tongue is as long as its body. This lizard swiftly shoots out its tongue to capture insects for food. Certain chameleons can quickly change color and even develop spots and streaks that make them seem to be part of their background.

A tree-climbing crab lives on many tropical islands. It is called the *coconut crab* because it cracks coconuts with its powerful claws and eats the sweet meat.

Lives of animals range from several hours to many years. An adult mayfly survives only a few hours or days. Some giant tortoises have lived more than 100 years.

The world's only known poisonous bird is the hooded pitohui, which lives on the island of New Guinea. This brilliantly colored orange-and-black bird has poison on its feathers and skin. This poison serves as a defense against hawks, snakes, and other enemies. It is the same type of poison as that carried by the deadly poison-dart frog of South America.

WORLD BOOK illustrations by Alex Ebel and Robert Kuhn

The platypus, a mammal, has a bill like a duck and lays eggs as birds do, *right.* But it nurses its young with milk as do other mammals. It lives only on mainland Australia and the island of Tasmania.

Animals are different from other living things in many ways. For example, the bodies of animals are made up of many cells. But the bodies of prokaryotes and most protists have only one cell. Like animals, plants and fungi also are made up of many cells. However, animals can move around. Most plants and fungi are held to one place in the soil by roots or rootlike structures. For a more complete discussion of the differences between the members of the five kingdoms, see the article on **Kingdom**.

No one knows exactly how many *species* (kinds) of animals there are. So far, scientists have *classified* (grouped) and named more than 1 $\frac{1}{2}$ million kinds of animals. Over half of these are types of insects. Many new species are discovered each year. Scientists believe there may be from 2 million to as many as 50 million kinds of animals alive today. Many other kinds of animals used to live on the earth but have died out. They include dinosaurs and dodos.

This article provides general information on animals other than human beings. It includes a classification table and pictures of many animals. Separate *World Book* articles give details about hundreds of animals. For information on human beings, see **Human being**.

Importance of animals

Animals and the web of life. Living things depend on one another. They are connected in what is sometimes called the *web of life*. Plants capture the energy from sunlight and use it to make roots, stems, leaves, flowers, and fruits. Animals eat the plants, or they eat other animals that feed on the plants. When animals die, their bodies decay and release materials that help fertilize the soil for plants.

Animals and plants are also connected in other ways. When animals breathe, they take in oxygen from the air and give off carbon dioxide. Green plants take in carbon dioxide and give off oxygen in a food-making process called *photosynthesis*. Many plants with flowers need insects or birds to carry their pollen from plant to plant. Without this transfer of pollen, these plants are not able to *reproduce* (create new individuals of their own kind). Some seeds are prickly and cling to the fur or feathers of animals. When the animals move from place to place, they take the seeds with them. In this way, the seeds get dropped in new areas where they can grow into plants.

The web of life relies on balance among its parts. A change in one part may mean disaster for others. For

WORLD BOOK illustration by John F. Eggert

Animals and plants are linked in a pattern of nature often called the *web of life*. This pattern can be seen in a garden or backyard. There, many kinds of animals keep themselves alive by eating some of the plants. Likewise, much of the food that plants need comes from the body wastes of animals. In most cases, natural forces keep the total number of living things in balance.

example, if all the trees in an area are cut down, then many animals that depend on them will die. For more information on how living things are linked, see Ecology.

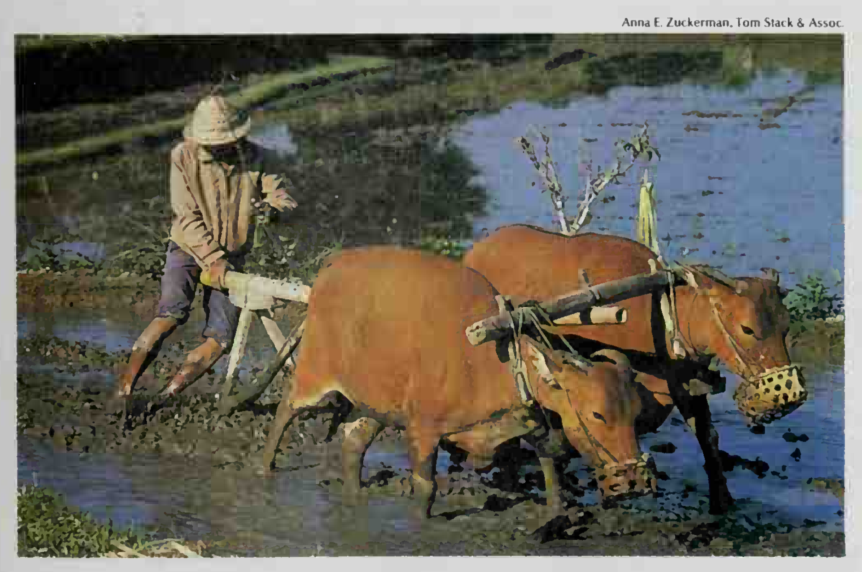
Animals and people. Animals have provided people with food and clothing since prehistoric times. Without animals, people would not have such things as meat, honey, eggs, wool, leather, or silk.

At least 10,000 years ago, people began *domesticating* (taming) animals. Some of these animals provide food and clothing. For example, cattle supply meat, milk, and leather. Chickens lay eggs. Sheep provide wool and meat.

Some domesticated animals help people work. Water buffaloes pull plows in Asian rice fields. Horses and camels carry people from one place to another. At first, people kept cats in their houses to catch rats and mice. They raised dogs to help them hunt and to warn them when danger approached. Today, cats and dogs are kept largely as pets.

Certain insects are useful to people. Bees make honey, which people harvest for food. Bees also pollinate many food crops, including fruits and vegetables. Silk comes from fiber made by silkworms.

Some animals harm people. On rare occasions, croc-



Melissa Grimes-Guy, Photo Researchers

Some animals make wonderful pets. Cats and dogs are favorite pets around the world. They are affectionate and loyal, and they provide companionship to people of all ages.

Larry Stessin, Photo Researchers

Some animals can be dangerous to people. A great white shark, *above,* usually feeds on tuna and other large sea animals. But sharks sometimes kill and eat people.

Anna E. Zuckerman, Tom Stack & Assoc.

Some animals help people work. Through the centuries, cattle and horses have pulled plows, carts, and wagons and carried products and riders on their backs. The water buffaloes shown at the left are helping a farmer plow a rice field in Southeast Asia.

odiles, lions, and tigers attack and kill people. So do grizzly bears and polar bears. Sharks sometimes kill and eat human beings. Bites from such poisonous snakes as rattlesnakes and cobras can cause death. The black widow spider has a poison that makes people extremely sick.

Some animals pass diseases along from person to person. Certain mosquitoes transmit malaria and yellow fever. Some ticks carry the bacteria that cause Lyme disease and Rocky Mountain spotted fever. Some animals cause disease themselves. Worms called *flukes,* which live in human organs, can cause *schistosomiasis.* This disease infects millions of people in many African, Asian, and Latin-American countries.

Kinds of animals

People often divide animals into various groups based on certain similarities the animals share. For example, some animals can be kept as pets, but others are wild. Arranging animals according to their similarities is a handy way of remembering and understanding them.

Some common ways of grouping animals. Animals can be grouped in many ways. They can be arranged according to whether they live on land or in water. Animals that live on land are known as *terrestrial animals.* They include cats, dogs, lizards, mice, and worms. Animals that live in water are called *aquatic animals.* They include eels, fish, lobsters, octopuses, and whales.

Animals can be arranged by the number of legs they have. Dogs, frogs, and lizards have four legs. Bats and birds have two legs. Insects have six legs, and spiders have eight. Snakes and worms have no legs.

Another way to group animals is according to how they move. Bats, most birds, and many insects fly. Whales, fish, and squid swim. Snakes and worms crawl. Antelope and cheetahs run. Frogs, kangaroos, and rabbits hop.

Some animals are *cold-blooded,* and others are *warm-blooded.* The bodies of cold-blooded animals are warm when their surroundings are warm and cool when their surroundings are cool. Warm-blooded animals, on the other hand, almost always have the same body temperature, regardless of the warmth of their surroundings. Birds, *mammals* (animals whose babies drink the mother's milk), and a few species of fish and insects are warm-blooded. All other kinds of animals are cold-blooded.

Animals are also commonly divided into groups according to whether they have backbones. *Invertebrates* do not have backbones, but *vertebrates* do. The vast majority of animals are invertebrates. They include clams, insects, jellyfish, sea urchins, snails, spiders, sponges, and worms. Birds, fish, mammals, and reptiles are vertebrates. So are *amphibians*—frogs, salamanders, and other animals that spend part of their lives in water and part on land.

The scientific classification of animals involves grouping animals according to the biological relationships among them. This orderly arrangement of animals depends in part on the features the animals share. In general, the more features they share, the more closely they are related. However, the scientific classification of animals is based mainly on the belief that certain animals share a common ancestor. Animals with a more recent common ancestor are more closely related than those who share an ancestor further back in time. In a somewhat similar way, brothers and sisters are more closely related than are cousins. Brothers and sisters share parents. First cousins share grandparents.

In classifying animals, *zoologists* (scientists who study animals) divide them into ever-smaller groups that have more and more features in common. The largest group is the kingdom Animalia itself, which includes all animals. Next, each animal is placed in a group called a *phylum.* Each phylum is divided into groups called

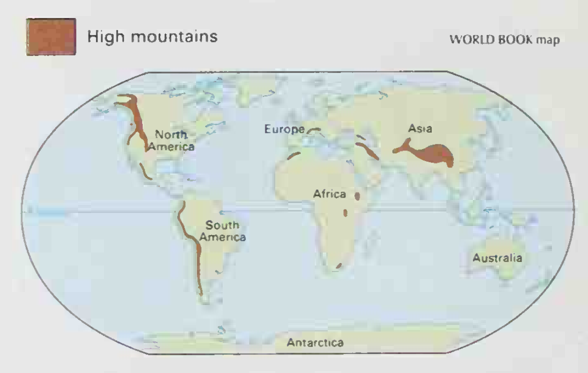
*Domesticated animal, life span in captivity.

classes. The classes are broken down into *orders,* and the orders into *families.* The families are split into *genera,* and the genera into *species.* The singular form of *genera* is *genus,* but the word *species* may be either singular or plural.

Among the animals that scientists have classified are about 13,000 species of flatworms; 50,000 species of clams, oysters, and other *mollusks* (soft-bodied animals, most of which have a hard shell); 1,000,000 species of insects; 30,000 species of spiders; 21,000 species of fish; 4,000 species of amphibians; 6,500 species of reptiles; 9,700 species of birds; and 4,500 species of mammals. Each species belongs to one phylum, one class, one order, one family, and one genus. For example, tigers belong to the kingdom Animalia, the phylum Chordata, the class Mammalia, the order Carnivora, the family Felidae, and the genus *Panthera.* They are members of the species *Panthera tigris.* Lions are related to tigers. They belong to the same kingdom (Animalia), phylum (Chordata), class (Mammalia), order (Carnivora), family (Felidae), and genus (*Panthera*) as tigers. But lions are classified in a different species—*Panthera leo,* also written simply as *P. leo.*

A *table* of animal classification, showing some of the major groups of animals, appears at the end of this article. See also **Classification, Scientific.**

Where animals live



Animals live in many kinds of places. The place where an animal lives is called its *habitat.* Each type of habitat presents a special challenge to animals. For example, animals that live in polar regions must withstand bitter cold. Those that inhabit the tropics face extreme heat. In spite of these challenges, animals can be found everywhere on the earth. They live on the highest mountains and in the deepest oceans. They roam the driest deserts and the wettest rain forests. They swim in fresh water and salt water.

Each habitat supports many kinds of animals. In most cases, the animals are the same kinds that have lived in those surroundings for thousands of years. As a result, the animals have developed bodies and ways of life that suit them to that particular habitat. No single species of animal can survive everywhere. For example, tropical fish from the Amazon River thrive in warm water but cannot withstand the cold streams of the Andes Mountains. On the other hand, many kinds of fish that live in the Arctic Ocean would die if they were exposed to the warm waters of the Caribbean Sea. However, some animals may travel between habitats from time to time. For example, African elephants eat both grass and tree parts and so move between grassland and forest. But these animals would not be able to withstand the freezing temperatures of the polar regions.

Some habitats, including many forests and grasslands, are being destroyed by human beings. The destruction of these habitats usually causes the death of many animals. When people convert grassland to farmland, for example, they destroy the homes and source of food of many species. Without these necessities, some animals will die immediately. Others may try moving to another grassland. But the new area may not have enough food and shelter to support the additional wildlife. As a result, many more animals will die.

This section tells about some of the major animals, grouped according to seven types of habitats: (1) mountains, (2) grasslands, (3) temperate forests, (4) tropical forests, (5) deserts, (6) polar regions, and (7) oceans. For descriptions and pictures of animals grouped according to the continent on which they live, see the articles on **Africa; Antarctica; Asia; Australia; Europe; North America; South America.**

Animals of the mountains

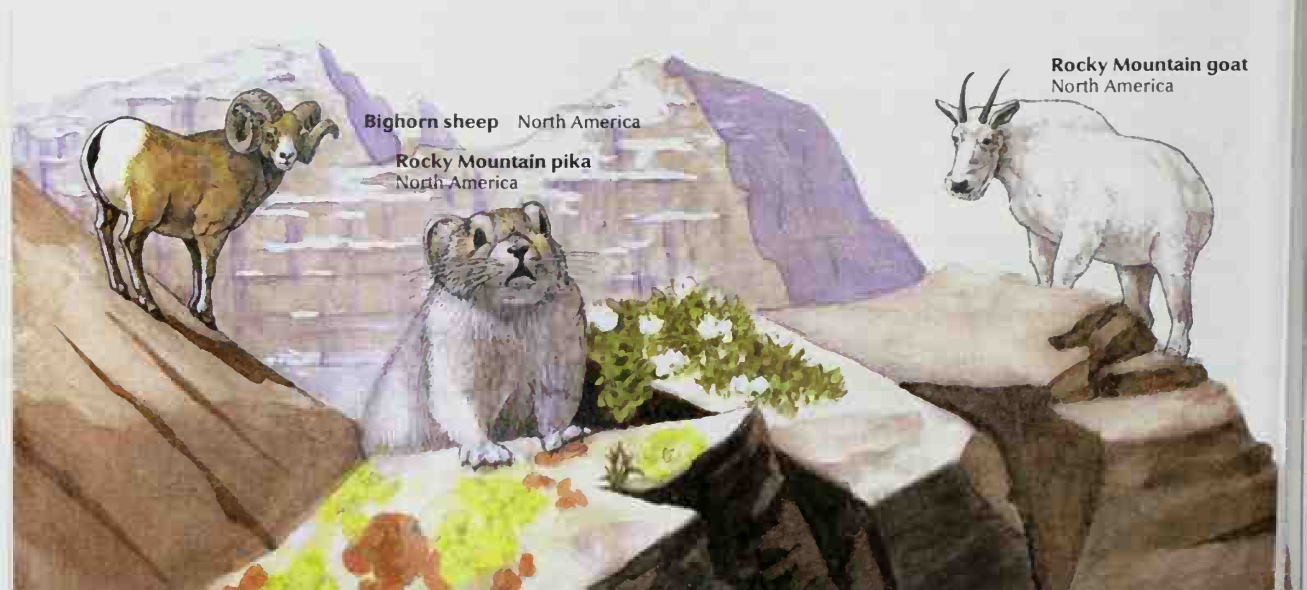
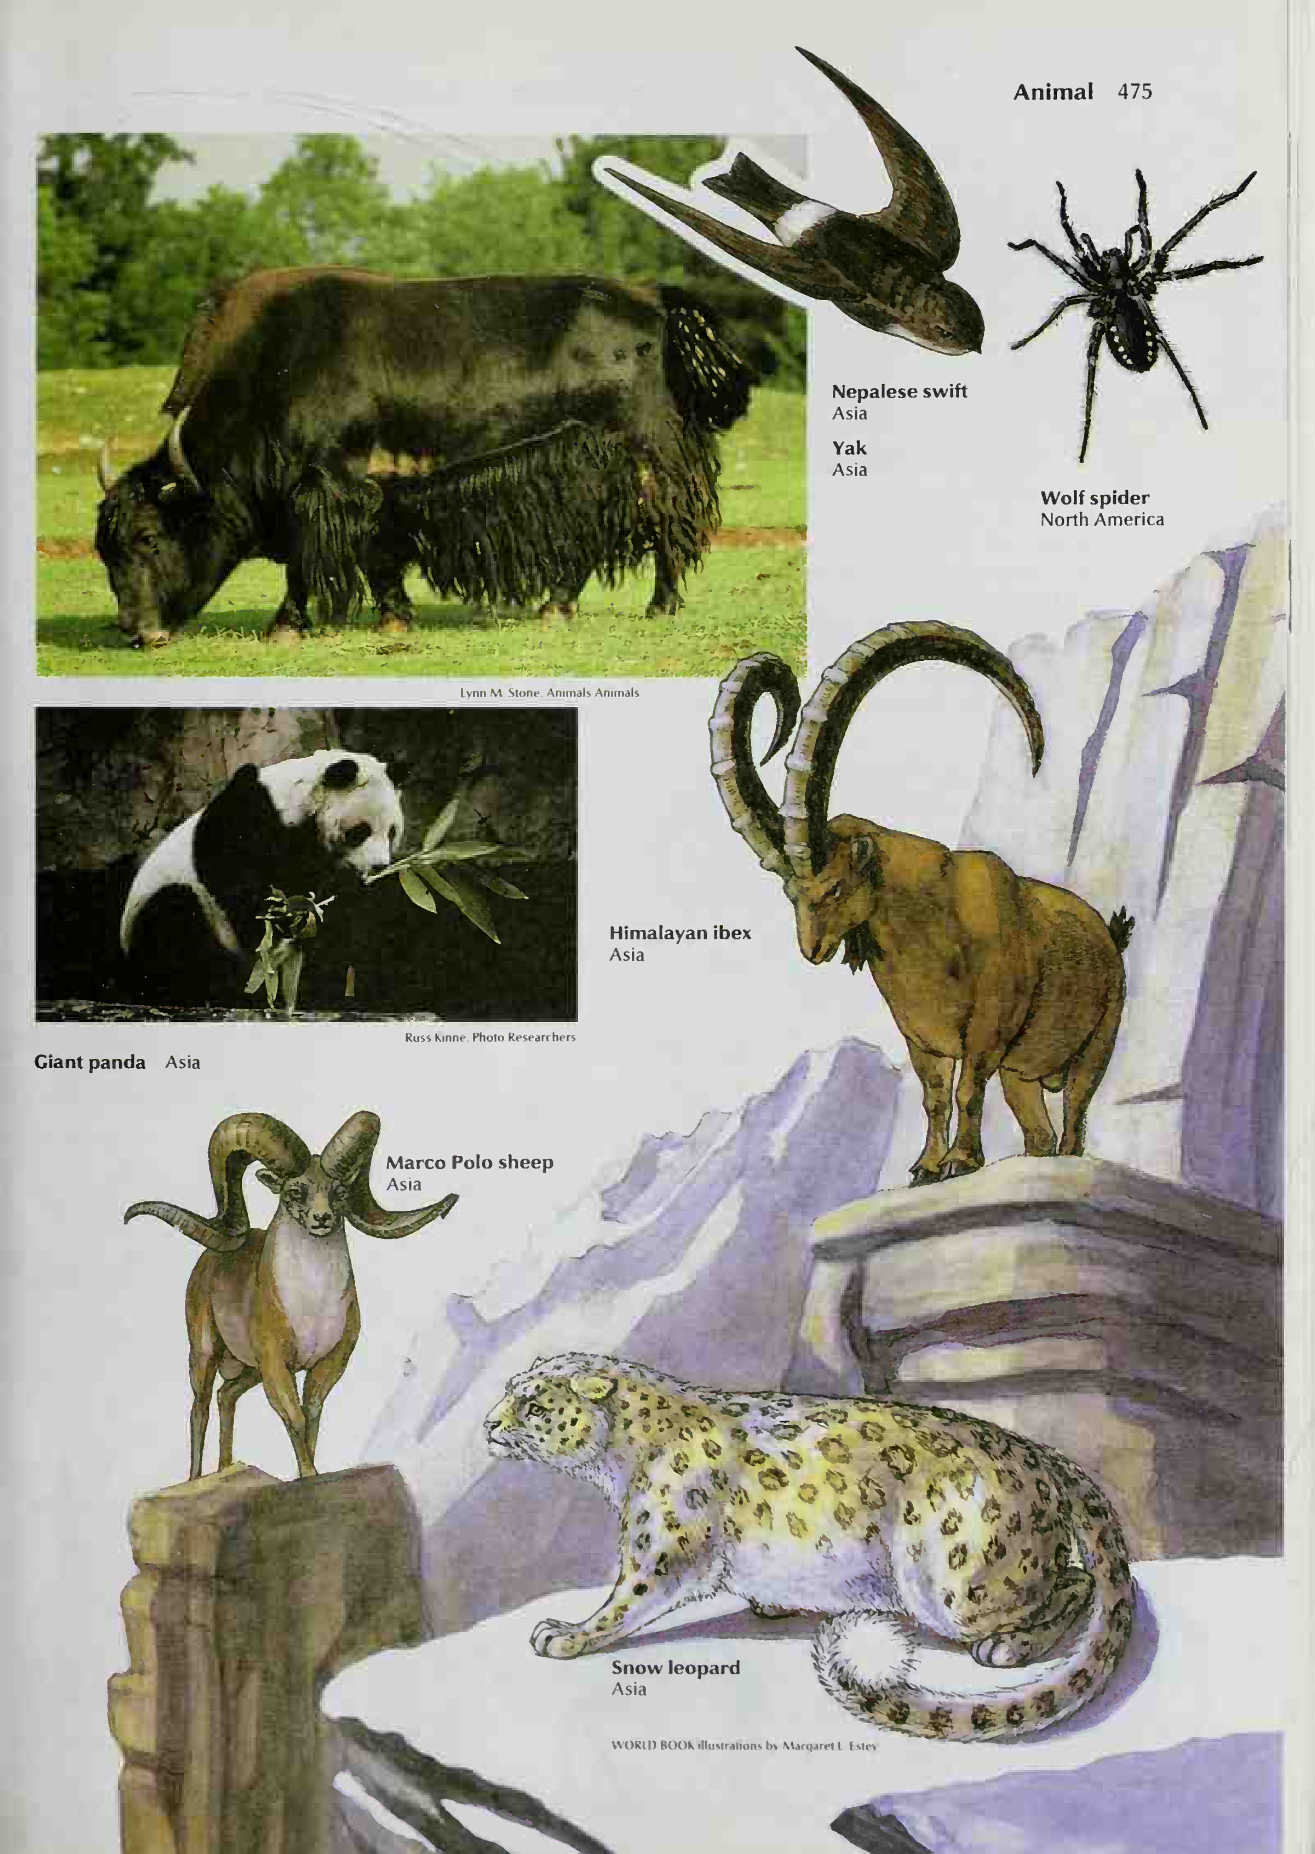
Vicuña South America

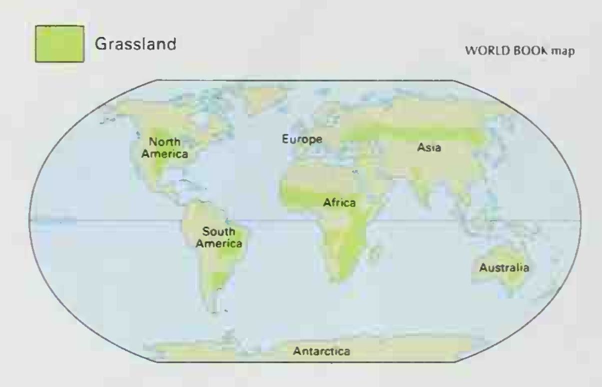


Jane Burton, Bruce Coleman Ltd



Chinchilla South America

Mountains support a variety of animal life. The numbers and kinds of animals found on mountains vary with altitude. More animals and more kinds of animals live at lower altitudes than at higher ones, largely because of the differences in climate between elevations. Generally, mountain climates become colder, wetter, and windier with increasing altitude. The air also gets thinner and has less oxygen. In addition, fewer plants are found at higher elevations, and therefore less food is available for animals.



Bears, deer, elk, and mink make their homes on the forested lower slopes and in the wooded or grassy valleys of mountains. Rainbow trout and graylings swim in mountain streams. Many mountains have meadows of grasses and herbs. These meadows are home to chinchillas, ibexes, llamas, vicuñas, and yaks. Butterflies, grasshoppers, and spiders also live there.

Above the *timber line*—that is, the line beyond which trees will not grow because of the cold—stand rocky cliffs and peaks dotted with shrubs, mosses, and other plants. Small meadows are also found there. Sure-footed bighorn sheep and mountain goats dwell among the windswept rocks, as do furry marmots and pikas. High on the snow-capped peaks, only a few insects, spiders, and ice worms can survive. Golden eagles and some other birds fly above the mountains. A large African vulture, Rüppell's griffon, has been known to soar as high as 36,600 feet (11,150 meters).

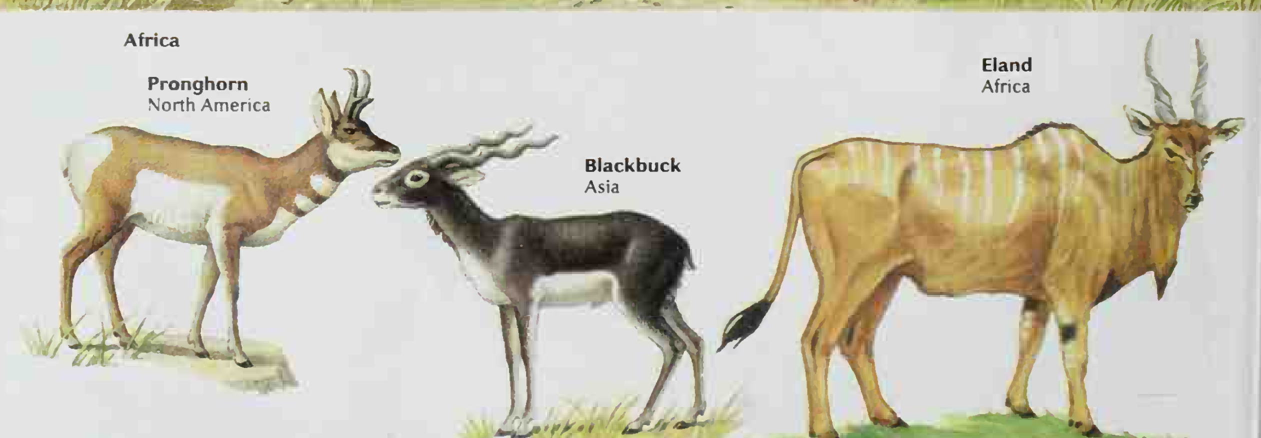
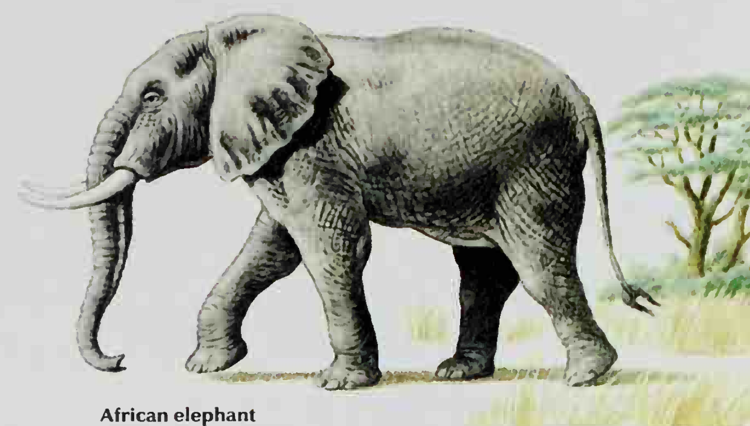
Animals of the grasslands



Grasslands include the prairies of North America, the pampas of South America, the plains of Europe, and the steppes of Asia. The savannas of east Africa have more grassland animals than any other area.

Rainfall in grasslands is seasonal, and animals sometimes travel great distances to find green grass. Gazelles, gnus, and zebras migrate by the thousands through the African savannas. Smaller groups of elephants and rhinoceroses also feed on the grasses there. Such meat-eating mammals as cheetahs, hyenas, and lions roam the savannas in search of prey. The savannas are also home to giraffes, jackals, ostriches, secretary birds, and termites. In addition, hippopotamuses live in and near bodies of water in African grasslands. Animals of other grasslands include the kangaroos and wombats of Australia, the cavies and rheas of South America, and the coyotes and prairie dogs of North America.



Many animals of the grasslands have become endangered due to loss of their habitat and to overhunting. The rich soils of grasslands are ideal for farming, and people have converted many such areas to farmland. Many of the large grassland animals are favorite big game for hunters. For example, the once-plentiful pampas deer of South America have become extremely rare. As the pampas are converted to farmland, the tall grass that grows there disappears. Without this grass, the pampas deer have no shelter and become easy prey. Bison once grazed in huge herds in the Great Plains of North America. But so many of these animals were killed by hunters or died as their grassland habitat was converted to farmland that they were nearly wiped out.

Animals of the temperate forests

Temperate forests consist largely of *deciduous trees* and *evergreen trees*. Deciduous trees shed their leaves in the fall and grow new ones in the spring. Evergreen trees have leaves that live two or more years. Some evergreens have needle-shaped leaves. Most temperate forests are in Asia, Europe, and North America. Australia also has some temperate forests.

Many forest animals have small bodies that allow them to move easily through the underbrush. Forest mammals include chipmunks, mice, opossums, porcupines, raccoons, skunks, and squirrels. Bears, deer, and wild boars also live in temperate forests. Bobcats and wolves were once common in woodland areas. However, so many of these predators have been hunted and trapped through the years that they have become rare.

Salamanders are often plentiful in temperate forests. They hide in the leaf litter or under rocks, where they feed on insects and other small organisms. In wet forests, slugs and other snails are common. Beavers, fish, frogs, muskrats, otters, salamanders, and turtles live in or near woodland streams, ponds, and lakes. Great numbers of birds nest in the trees and shrubs.

Many temperate forests have been cleared for farms and cities, and many others have been cut down for fuel and lumber. This *deforestation* (destruction of forests) places woodland animals in danger. Extensive logging in the Pacific Northwest of the United States, for example, has destroyed much of the habitat of the spotted owl, threatening the existence of that species.

WORLD BOOK illustrations by John F. Eggert and Stan Galli

Tropical forests stay warm all year and receive plentiful rainfall. These forests are found in Africa, Asia, Australia, Central and South America, and the Pacific Islands. More kinds of animals live in tropical forests than in any other habitat. Scientists estimate that perhaps as many as 30 million species of tropical animals have not even been discovered yet.

Insects make up the largest single group of animals that live in tropical forests. They include brightly colored butterflies, huge colonies of ants, mosquitoes, and camouflaged stick insects. Spiders are also plentiful. Many tropical birds, such as quetzals and parrots, are spectacularly colored.

The broad leaves of trees in tropical forests form a thick overhead covering called a *canopy* that blocks nearly all sunlight from reaching the forest floor. Many kinds of animals live in the canopies of tropical forests. They include harpy eagles and toucans; tree frogs; flying dragons; spider monkeys and howlers; gibbons and orangutans; sloths; slow lorises; tree boa constrictors; bats; and wasps, beetles, and leaf-cutting ants.

Jaguars, tapirs, and bushmaster snakes live on the ground in tropical forests. Chimpanzees and lowland gorillas alternate between the ground and the trees. Crocodiles, fish, and turtles inhabit rivers and ponds.

People are rapidly destroying tropical forests for wood and for farming. The continuing destruction of this habitat means that many animals will disappear forever. Scientists believe countless species have already been wiped out.

Animals of the deserts

Most deserts lie near the edges of the tropics. Food and water are often scarce in deserts, and temperatures in the summer can be scorching. Despite these conditions, many kinds of animals live there. They include geckos, iguanas, and skinks; bees, butterflies, and moths; spiders; elf owls and roadrunners; sidewinders; dorcas gazelles and mule deer; and bobcats, coyotes, and dingoes.

Animals of the deserts have developed special bodies and ways of life that enable them to survive the extreme heat. Centipedes, kangaroo rats, rattlesnakes, and scorpions spend the day in burrows. They come out to search for food only when temperatures drop at night. Many insects, lizards, and tortoises can tolerate high desert temperatures and are active in the daytime. But even they must retreat underground or find the shade of a tree during the hottest part of the day. Some snails, insects, frogs, lizards, mice, and ground squirrels *estivate* (sleep through the summer).

Many desert dwellers have light-colored skin, which helps keep them cool by reflecting sunlight. Desert foxes and hares have long ears. When overheated, these animals move to a cool cave or burrow where they can get rid of excess body heat through their ears. The Cape ground squirrel makes its own shade by using its fluffy tail like a parasol. Fairy shrimp and spadefoot toads may spend months or years underground waiting for rain to create ponds. Then they quickly feed and reproduce before the ponds dry again.

Animals of the polar regions

Animals that live in polar regions must withstand extremely cold temperatures. No land animals except ice worms and a few species of insects live in polar regions that have ice and snow the year around. But the seas of the Arctic and Antarctic have large numbers of wildlife, including fish, giant sponges, whales, and tiny shrimplike creatures called *krill.* In addition, polar bears, sea lions, and walruses spend much of their time on floating sheets of ice in the Arctic. Penguins and seals live on the Antarctic coast.

Many animals inhabit the vast arctic *tundras* (cold treeless plains) of northern Asia, North America, and Europe. They include caribou, ermine, musk oxen, reindeer, lemmings, snowy owls, and wolves. Shallow ponds in the region provide a place for mosquitoes and many other insects to lay their eggs. These insects serve as food for the birds that migrate to the tundra each summer to nest.

Animals that live in polar regions have developed bodies and ways of life that enable them to deal with the frigid winter weather. Caribou, musk oxen, and polar bears have thick fur, which helps them stay warm. The arctic fox and arctic hare have short ears and tails that keep them from losing much body heat. Arctic ground squirrels *hibernate* (sleep through the winter). They curl up in a burrow, and their body temperature drops, saving energy during the long winter. They also do not eat in the winter. They live off fat stored in their bodies.

Animals of the oceans

Animals of many kinds are found everywhere in the vast oceans. Some of the smallest animals live in the sea, as does the world's largest, the blue whale. Cod, halibut, seals, and whales swim the frigid waters of the polar regions. Lobsters, sea urchins, and many types of brightly colored fish inhabit coral reefs in warm tropical seas. Some ocean animals live near the shore—in shallow water, in tide pools, and on rocks. They include anemones, barnacles, mussels, octopuses, and starfish. Other marine animals—mostly such tiny shrimplike creatures as krill and copepods—are found in the open sea. Krill and some species of copepods form part of the group of organisms called *plankton.* Many fish and some whales feed on plankton.

The great depths of the ocean are completely dark, and the water there is bitterly cold. Even so, anglerfish, clams, and certain other creatures live there. On the other hand, flyingfish, manta rays, marlins, and porpoises generally swim near the ocean surface. Albatrosses, gulls, and petrels fly above the sea.

Oceans provide people with such foods as crab, fish, lobster, and shrimp. However, the demand for seafood has led to the overfishing of halibut, herring, and some other marine animals. Millions of dolphins, which are mammals, have drowned in fishing nets that were intended to catch cod, tuna, and other fish. In addition, spills of toxic materials and other forms of pollution have reduced the numbers of some ocean species.

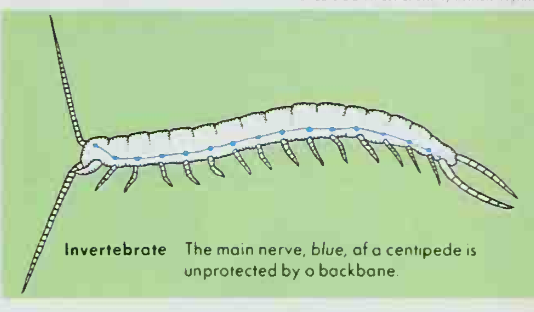
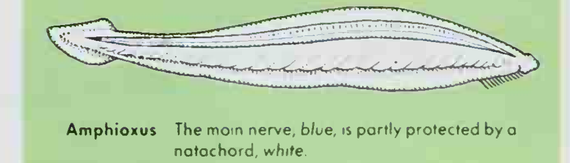
The bodies of animals



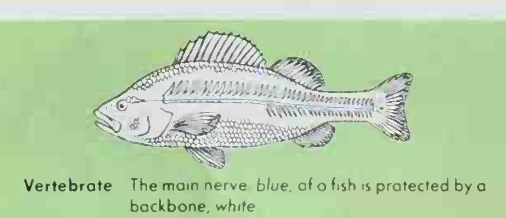
Animals have special body features that enable them to survive in their environment. These special features, called *adaptations,* result from the ability animal species have to *adapt* (adjust) over time to changes in their surroundings. Adaptations for survival enable animals to move about, to eat, to breathe, and to sense their environment. Legs, wings, and fins help animals move. Teeth and jaws help them eat. Lungs and gills help them obtain oxygen. Eyes and ears help them find food and detect predators.

Animals live in many kinds of environments. The body features of an animal that work well in one type of environment may not work in others. For example, the adaptations that enable fish to breathe in water do not let them breathe on land. Even in the same environment, animals may have different adaptations for survival. Shrimp, fish, and sea turtles can all swim in the ocean, but they have different body features for doing so.



Invertebrates and vertebrates

The animal kingdom is often divided into two main groups--animals without backbones, called *invertebrates,* and animals with backbones, called *vertebrates.* Invertebrates include sponges, worms, centipedes, starfish, mollusks, and insects. Vertebrates include fish, amphibians, reptiles, birds, and mammals. Invertebrates are commonly known as the *lower animals.* Vertebrates are known as the *higher animals.* The backbone of a vertebrate helps protect the *spinal* (main nerve) *cord.* The main nerve cord of invertebrates is unprotected. A small sea animal, the amphioxus, has a *notochord,* which is a rod of cartilage that serves as a backbone and partly protects the animal's main nerve. The amphioxus is considered to be a link between the lower animals and the higher animals.



WORLD BOOK illustrations by Patricia Wynne

Invertebrate The main nerve, *blue,* of a centipede is unprotected by a backbone.

Amphioxus The main nerve, *blue,* is partly protected by a notochord, *white.*

Vertebrate The main nerve, *blue,* of a fish is protected by a backbone, *white.*

Shrimp have tiny swimming legs, fish have fins and muscular tails, and turtles have flippers. Because animals adapt to their surroundings in many ways, there is a wide diversity of animals in any environment.

This section describes some of the ways animal bodies are adapted for moving, eating, breathing, and sensing the environment. For information on the basic process of adaptation, see **Adaptation.**

Adaptations for moving about

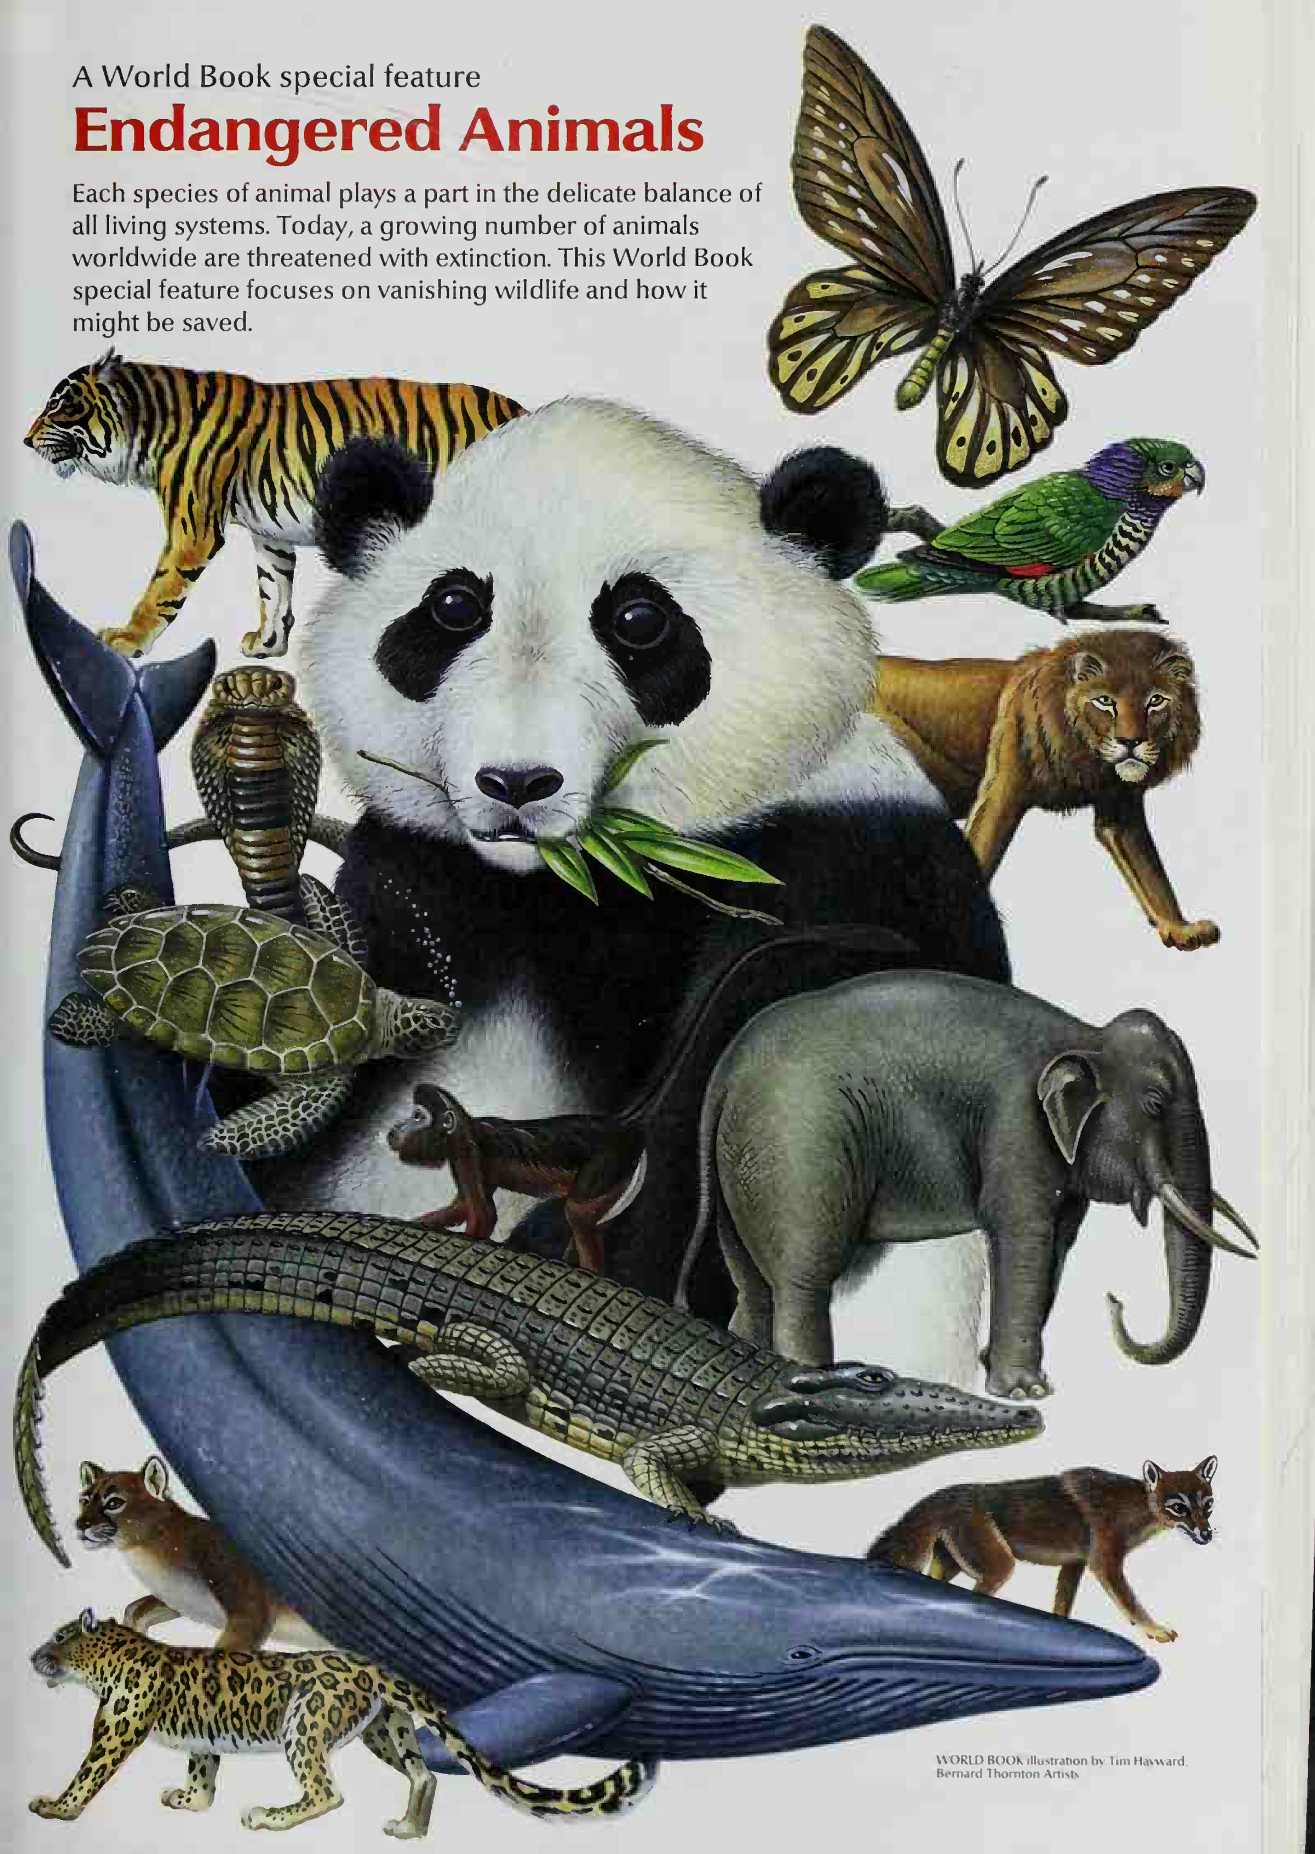
Legs and feet. Mammals, birds, insects, and many reptiles and amphibians have legs with feet that enable them to walk or run on land. Most amphibians, mammals, and reptiles walk on four legs. Birds and people walk on two. Insects have six legs, and spiders have eight. Millipedes may have up to 200 legs.

Animals can crawl without legs and feet. Such tiny creatures as planarians and other flatworms slide by moving many small hairlike structures, called *cilia,* back and forth like miniature oars. Snails move by coating the ground with a sticky fluid from their bodies. They then crawl through the fluid using a muscular organ called a *foot.* Most snakes slide along the ground by bending their bodies from side to side. An earthworm crawls through the soil by alternately lengthening and shortening parts of its body.

Many walking and crawling organisms live in water. Crabs and lobsters have legs that enable them to walk across the bottom of a body of water.

Wings. Three groups of animals have the ability to fly under their own power: (1) insects, (2) bats, and (3) birds. Most insects have two pairs of wings. Muscles inside the *thorax* (middle section of an insect's body) move the wings up and down.

Bats are the only mammals with wings. Batwings are



Jacana

Long, powerful legs and a stride of 15 feet (4.6 meters) make the ostrich one of the fastest land animals. Ostriches can reach speeds as high as 40 miles (64 kilometers) per hour.

A World Book special feature

Endangered Animals

Each species of animal plays a part in the delicate balance of all living systems. Today, a growing number of animals worldwide are threatened with extinction. This World Book special feature focuses on vanishing wildlife and how it might be saved.

WORLD BOOK illustration by Tim Hayward, Bernard Thornton Artists

What is an endangered animal?

There are three main classifications for animal species in danger of becoming extinct: (1) endangered, (2) vulnerable, and (3) lower risk. Endangered species face the most serious threat of extinction. They require direct human protection for survival. Vulnerable species are sometimes referred to as *threatened species.* They are abundant in some areas, but their numbers are decreasing or they face serious dangers. Lower risk species either have small populations within a narrow geographic area or are thinly scattered throughout a wider range.

An age of mass extinction?

The earth has had several periods of mass extinction. Many scientists believe we are living in one now. In past extinctions, animals died out due to natural causes. Today, human activities are mainly responsible for the destruction of species.

Vulnerable. The giant anteater inhabits Central and South America. As the population of Central America has grown, people have destroyed much of the anteater's habitat to make way for farms and cities. As a result, the animal has disappeared from much of this region. In South America, the giant anteater is hunted for sport.

WORLD BOOK illustrations by Norman Weaver, Colin Newman, and John Eggert

Endangered. The common sturgeon lives in the waters of Europe. Overfishing of this species and the pollution of its environment have contributed to its decline. The construction of dams and other waterworks on the rivers where common sturgeons migrate to *spawn* (breed) has also harmed these fish.

Extinct. Dinosaurs died out from natural causes about 65 million years ago. Many scientists believe that these huge reptiles became extinct because of a rapid change in climate and the dinosaurs' inability to survive it. Today, a number of human activities, such as the destruction of tropical rain forests and pollution of the air, may result in a change in the earth's climate called *global warming.* No one knows how many animals might fail to survive such a change.

Lower risk. Harpy eagles are among the largest and strongest eagles. They are thinly scattered over a wide range, from southern Mexico to eastern Bolivia, southern Brazil, and northern Argentina. The destruction of tropical rain forests means loss of habitat for these rare birds of prey.

e

by

How animals become endangered

Many factors contribute to endangerment. They include the destruction of habitats, pollution, trade in animal products, overhunting, the introduction of new species to an area, and the growing human population. In many cases, these factors are linked.

The destruction of habitats is one of the main threats to animals. The photo at the right shows the beginning of *slash-and-burn cultivation* of part of a rain forest. Trees are chopped and burned to make way for farmland. However, the soil in such areas is relatively unfertile and will support crops for only a few years before it is exhausted. Then more trees will have to be cleared to create more farmland. Meanwhile, the rain forest, which has more species than any other habitat, is being destroyed—and countless species along with it. Some experts estimate that more than 50 rain forest species become extinct each day because of human activities.

© Gustavo Gilabert, JB Pictures

Trade in animal products. Some animals become endangered because their fur or some other body part is considered valuable. For example, rhinoceros horns are prized in some parts of the world. In some cases, the animals themselves are valued. For instance, certain tropical birds are valued by bird collectors. The photograph at the left shows some of the booty seized from *poachers* (illegal hunters) who killed protected animals.

© Mark N. Boulton, NAS

Other factors that threaten animals

- **The growing human population** will strain existing resources and require more land in which to live. As a result, more animal habitats will be destroyed.
- **Introduction of new species** to an area can mean disaster for native animals. When Europeans landed in Hawaii and other Pacific Islands, rats escaped from their ships and then preyed on native birds. Domestic cats introduced by Europeans also killed native birds. As a result, more than 100 kinds of Pacific Islands birds have become extinct since 1600.
- **Overhunting a species** can threaten it with extinction. Sometimes animals are hunted because people consider them a pest. The red wolf of North America was trapped, hunted, and poisoned for this reason.

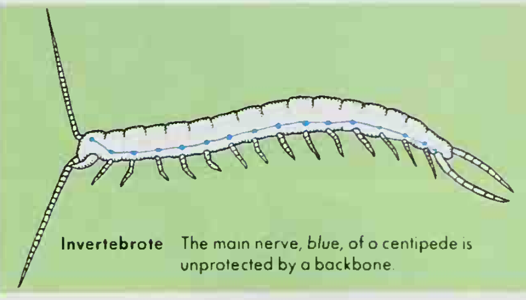
Saving the spotted owl: A policy issue

The spotted owl inhabits the forests of the Pacific Northwest of the United States. In the late 1980's, conservationists became concerned that lumber companies were destroying the habitat of the owl. But loggers argued that unless they could continue to cut down the trees, they would lose their jobs and face economic hardship. How would you solve this problem?

© John Neel, Tom Stack & Associates

Pollution in all its forms—whether of the land, the air, or the water—is a serious threat to animals. An oil spill killed this cormorant.

The bodies of animals



Animals have special body features that enable them to survive in their environment. These special features, called *adaptations,* result from the ability animal species have to *adapt* (adjust) over time to changes in their surroundings. Adaptations for survival enable animals to move about, to eat, to breathe, and to sense their environment. Legs, wings, and fins help animals move. Teeth and jaws help them eat. Animals at risk around the world

Animals are endangered throughout the world, from the sandy deserts of Africa to the steamy forests of South America, and from the windswept plains of central Asia to the snow-capped mountains of Europe and the cool waters of North America. This map shows where some endangered and vulnerable species live.

Some endangered or vulnerable animals

Name	Distribution	Comments
Adalbert's (Spanish imperial eagle)	Spain, Morocco, Algeria	Overhunted; harmed by pesticides, destruction of forest nesting sites, reduction of food supply
American crocodile	Southeastern United States, Mexico, Central and South America, Caribbean islands	Overhunted for its hide; suffers from destruction of habitat
Arabian oryx	Arabian Peninsula	Overhunted for its meat, for its hide, and for sport; saved by captive breeding program
Asiatic lion	India	Formerly wide-ranging; now survives only in the Gir Forest in the Gujarat state of western India; has been overhunted for sport; also suffers loss of habitat
Cheetah	Africa to India	Deprived of habitat; overhunted for sport
Florida cougar (or Florida panther)	United States	Overhunted because people consider it a pest; suffers from habitat destruction; once ranged from eastern Texas through Florida and north into Arkansas, Tennessee and South Carolina; doubtful whether any live outside Florida now
Golden lion tamarin	Brazil	Declining due to habitat destruction and overcollection for medical research and for pets; being saved through captive breeding
Grevy's zebra	Kenya	Overhunted for its skin and for sport
Malayan tapir	Southeast Asia	Forest habitat being destroyed for farms and pasture
Queen Alexandra's birdwing butterfly	Papua New Guinea	Habitat being damaged by logging and expanding agriculture
Red wolf	Southeastern United States	Habitat being destroyed; has been hunted, trapped, and poisoned because people consider it a pest
Zanzibar red colobus	Zanzibar (Tanzania)	Lives in an extremely restricted range; habitat being destroyed

IUCN (International Union for the Conservation of Nature and Natural Resources) includes about 2,100 endangered species and subspecies of animals on its *Red List of Threatened Animals.* It also classifies about 3,100 types of animals as *vulnerable* (the approximate equivalent of the U.S. Fish and Wildlife Service's *threatened* category) and more than 2,100 kinds as *lower risk.* The list does not include the rain forest species—mainly insects—that are destroyed before they are identified.

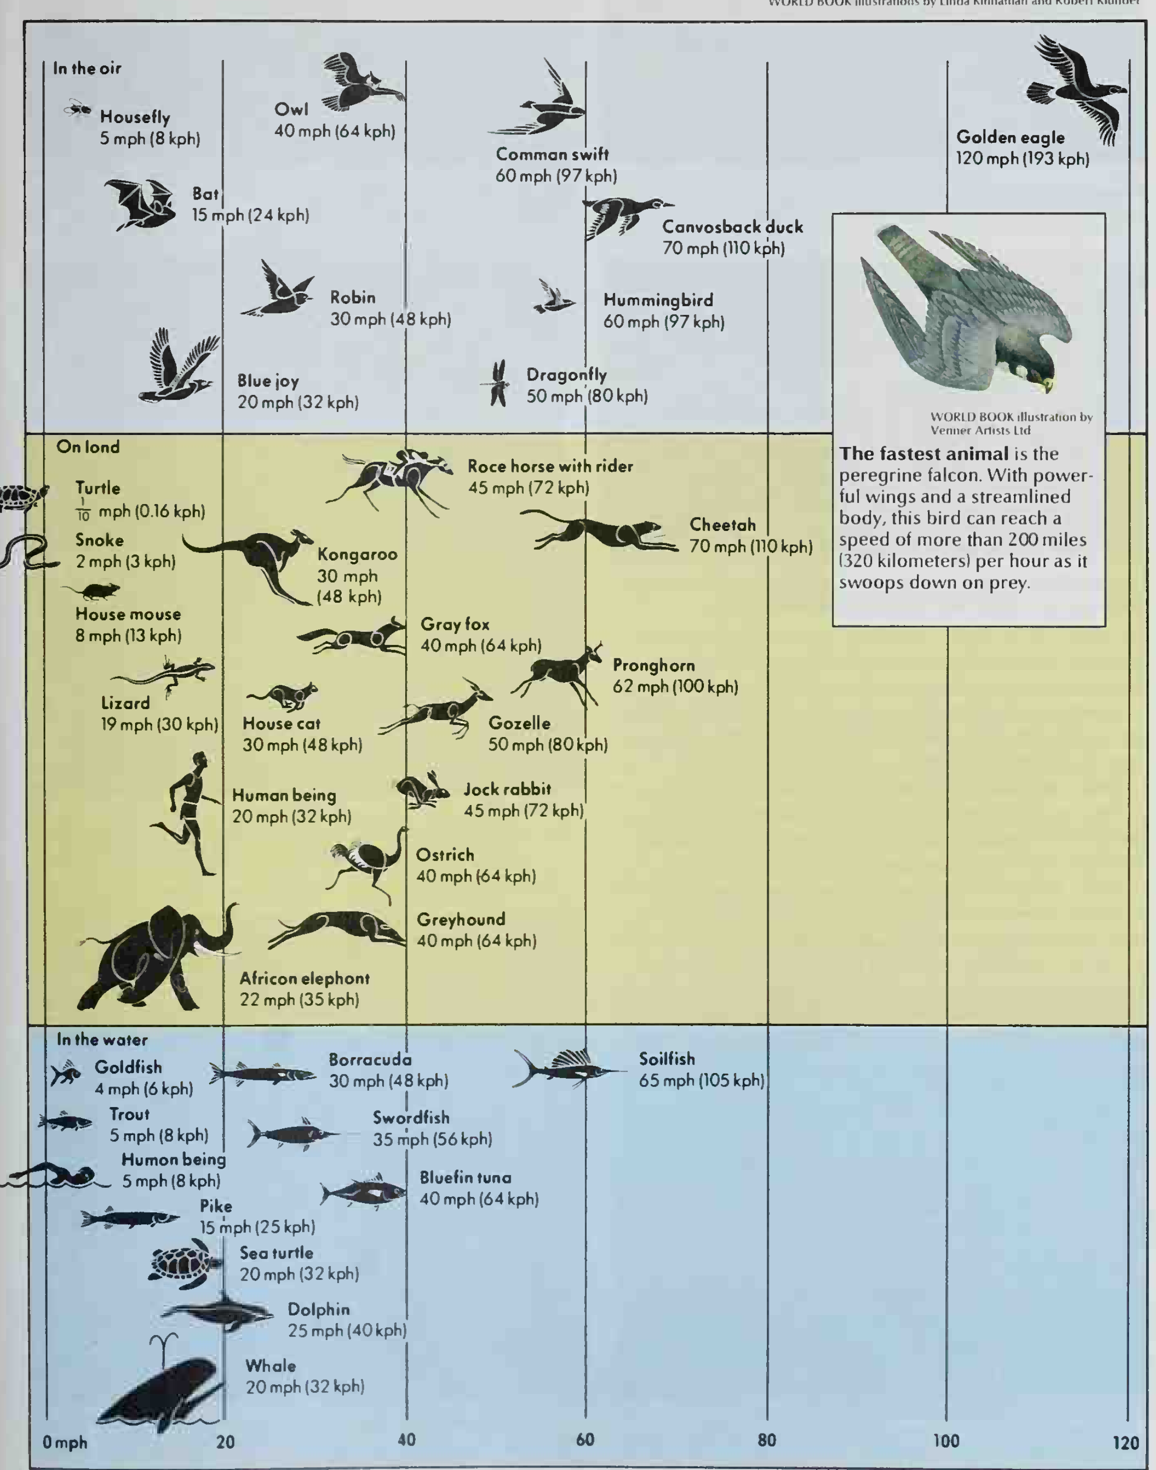
Suffers from habitat disruption; formerly plentiful in the states of New South Wales and Queensland; only one known colony survives in Queensland
Mountain gorilla
Mountain chains of western Rwanda, southwestern Uganda, eastern Congo (Kinshasa)
Suffers from poaching and from loss of habitat to farmland; habitat also damaged in a civil war in Rwanda
ANTARCTICA



Several organizations compile lists of animals they consider endangered. They do not always agree on the status of an animal or on the definition of endangered status. For example, IUCN (International Union for the Conservation of Nature and Natural Resources) suspects that Przewalski's horse may no longer occur naturally in the wild. IUCN puts this species in a category with other animals that are almost certainly extinct. However, more than 1,500 Przewalski's horses live in captivity, and scientists have begun a program to release captive-bred Przewalskis into the wild. Because some of these horses still exist, the United States Fish and Wildlife Service classifies the animal as endangered. With the exception of Przewalski's horse, all animals in this special feature are classified as endangered or vulnerable by IUCN.

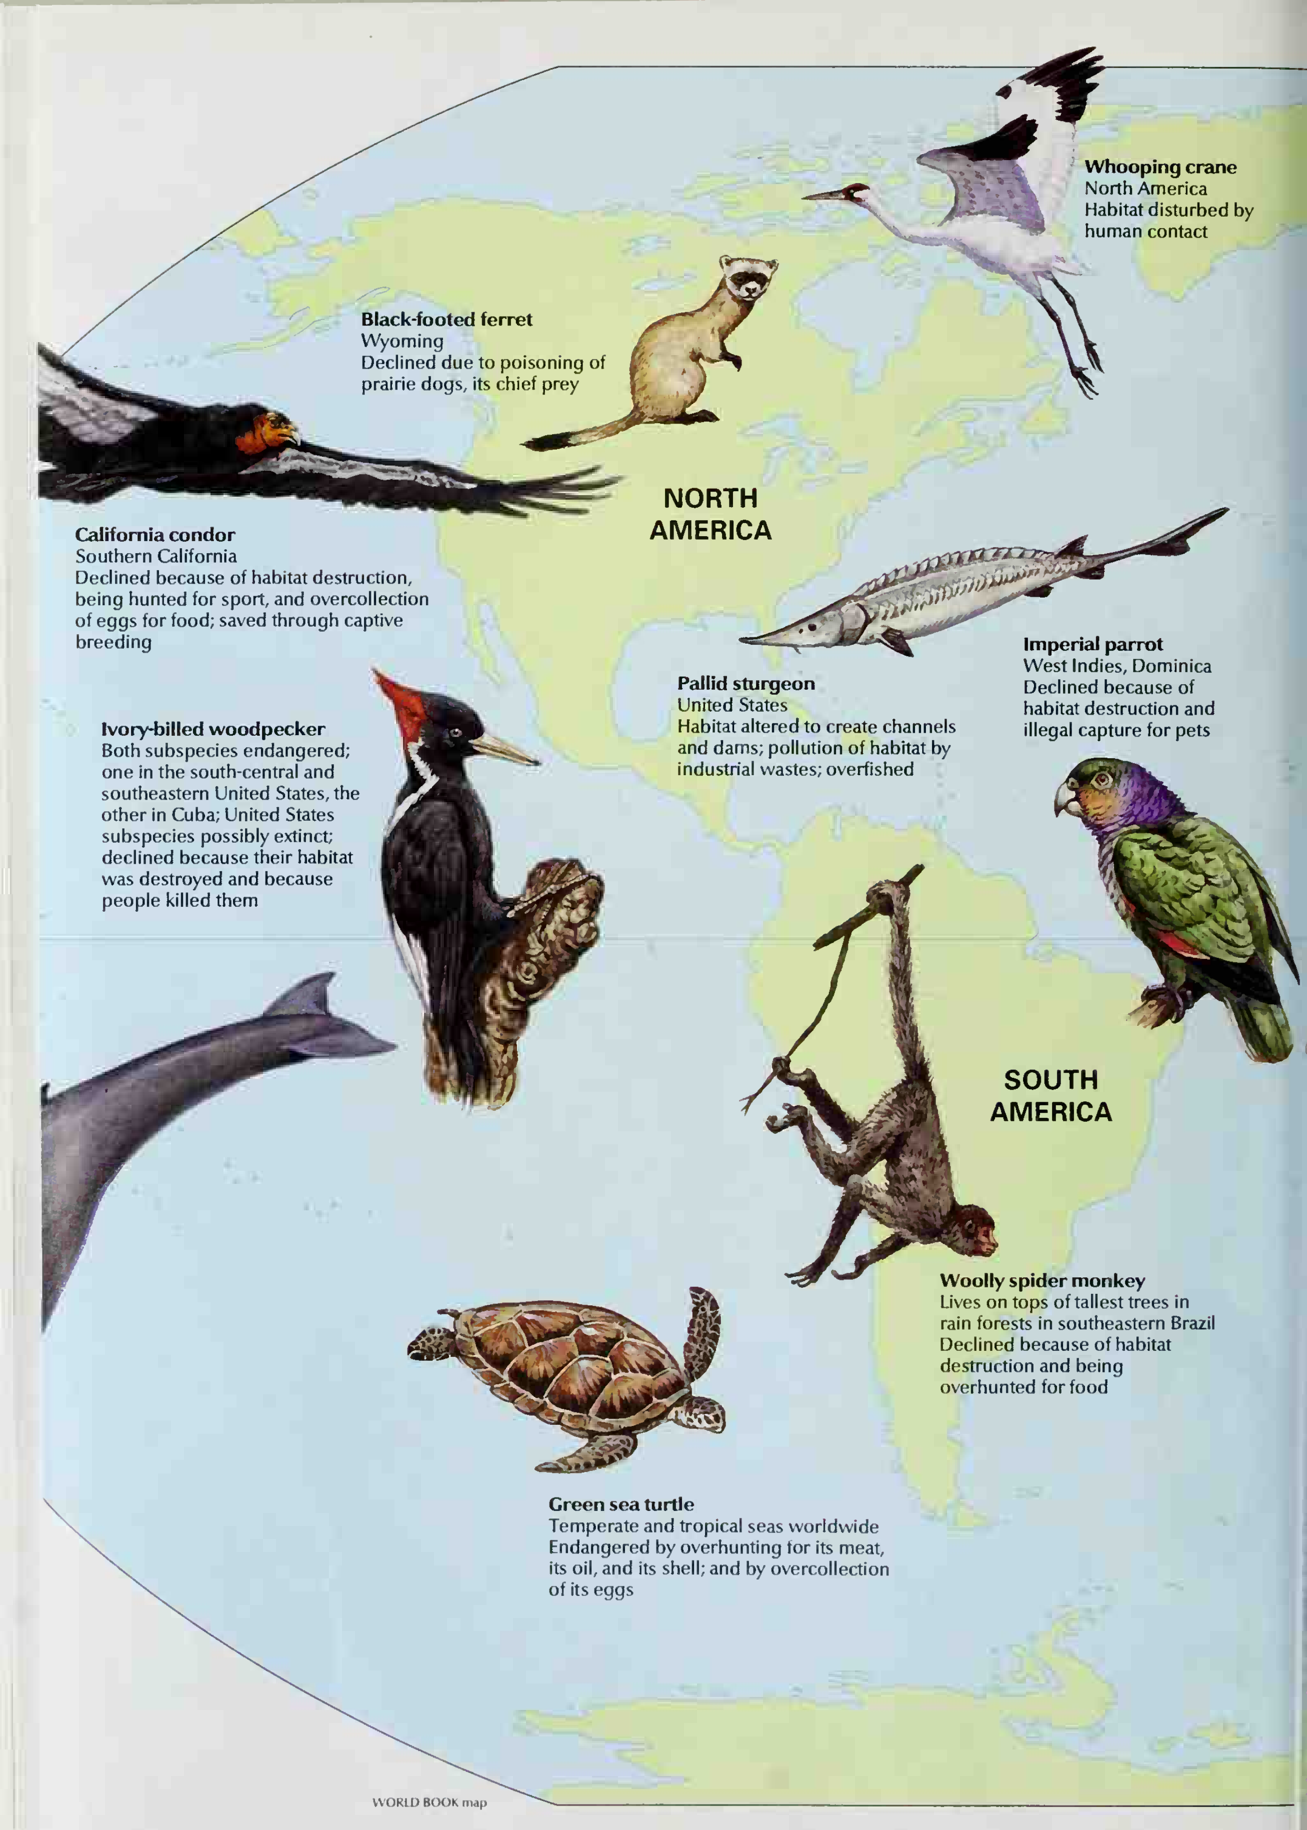
Comparative speeds of animals



The speeds of animals vary greatly. Birds are the fastest of all animals, with flying speeds of more than 200 miles (320 kilometers) per hour. The speediest land animals outstrip the fastest water animals. Many of the figures given in the table below are estimates because scientists have difficulty measuring the speeds of wild animals. In addition, the maximum speed of an animal may differ widely from its usual speed. A rabbit runs faster than a greyhound for a short time. But the greyhound can keep up its speed for longer distances.

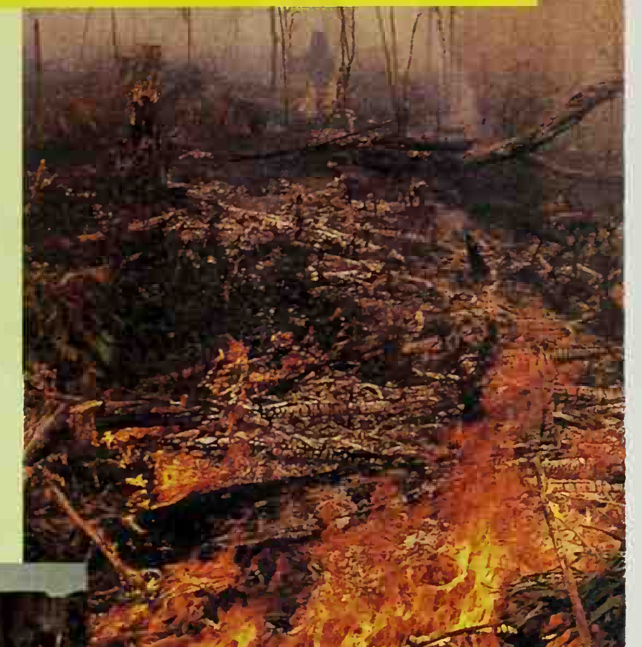
The fastest animal is the peregrine falcon. With powerful wings and a streamlined body, this bird can reach a speed of more than 200 miles (320 kilometers) per hour as it swoops down on prey.



Whooping crane
North America
Habitat disturbed by human contact
Black-footed ferret
Wyoming
Declined due to poisoning of prairie dogs, its chief prey
NORTH AMERICA
California condor
Southern California
Declined because of habitat destruction, being hunted for sport, and overcollection of eggs for food; saved through captive breeding
Imperial parrot
West Indies, Dominica
Declined because of habitat destruction and illegal capture for pets
Pallid sturgeon
United States
Habitat altered to create channels and dams; pollution of habitat by industrial wastes; overfished
Ivory-billed woodpecker
Both subspecies endangered; one in the south-central and southeastern United States, the other in Cuba; United States subspecies possibly extinct; declined because their habitat was destroyed and because people killed them
SOUTH AMERICA
Woolly spider monkey
Lives on tops of tallest trees in rain forests in southeastern Brazil
Declined because of habitat destruction and being overhunted for food
Green sea turtle
Temperate and tropical seas worldwide
Endangered by overhunting for its meat, its oil, and its shell; and by overcollection of its eggs
WORLD BOOK map

How animals become endangered

Many factors contribute to endangerment. They include the destruction of habitats, pollution, trade in animal products, overhunting, the introduction of new species to an area, and the growing human population. In many cases, these factors are linked.

The destruction of habitats is one of the main threats to animals. The photo at the right shows the beginning of *slash-and-burn cultivation* of part of a rain forest. Trees are chopped and burned to make way for farmland. However, the soil in such areas is relatively unfertile and will support crops for only a few years before it is exhausted. Then more trees will have to be cleared to create more farmland. Meanwhile, the rain forest, which has more species than any other habitat, is being destroyed—and countless species along with it. Some experts estimate that more than 50 rain forest species become extinct each day because of human activities.

© Gustavo Gilabert, JB Pictures

Trade in animal products. Some animals become endangered because their fur or some other body part is considered valuable. For example, rhinoceros horns are prized in some parts of the world. In some cases, the animals themselves are valued. For instance, certain tropical birds are valued by bird collectors. The photograph at the left shows some of the booty seized from *poachers* (illegal hunters) who killed protected animals.

© Mark N. Boulton, NAS

Other factors that threaten animals

- **The growing human population** will strain existing resources and require more land in which to live. As a result, more animal habitats will be destroyed.
- **Introduction of new species** to an area can mean disaster for native animals. When Europeans landed in Hawaii and other Pacific Islands, rats escaped from their ships and then preyed on native birds. Domestic cats introduced by Europeans also killed native birds. As a result, more than 100 kinds of Pacific Islands birds have become extinct since 1600.
- **Overhunting a species** can threaten it with extinction. Sometimes animals are hunted because people consider them a pest. The red wolf of North America was trapped, hunted, and poisoned for this reason.

Saving the spotted owl: A policy issue

The spotted owl inhabits the forests of the Pacific Northwest of the United States. In the late 1980's, conservationists became concerned that lumber companies were destroying the habitat of the owl. But loggers argued that unless they could continue to cut down the trees, they would lose their jobs and face economic hardship. How would you solve this problem?

© John Neel, Tom Stack & Associates

Pollution in all its forms—whether of the land, the air, or the water—is a serious threat to animals. An oil spill killed this cormorant.

How human beings protect animals

If people do not offer endangered animals some kind of protection, such animals will become extinct. Through the years, concern about vanishing wildlife has led people to take a number of steps. Some animals are protected in wildlife refuges or parks. Others live in zoos. Many zoos and research centers breed endangered animals with the hope of returning their offspring to the wild.

E. R. Degginger

Wildlife reserves and national parks may represent the last hope of survival for some species. In such areas, animals are protected by law from hunters. However, poachers still remain a problem. Zebras and gnus are among the many animals that roam the protected lands of Tarangire National Park in northern Tanzania, *above.*

LuRay Parker, Wyoming Game and Fish Department

Breeding in captivity. Some animals have been saved by breeding them in captivity. In the mid-1980's, black-footed ferrets, which lived in Wyoming, were on the verge of extinction. In 1986, the last surviving community of these animals—consisting of 18 individuals—was rounded up to establish a captive-breeding program. In 1991, federal and state wildlife officials began releasing black-footed ferrets into southeast Wyoming. Before being released, each ferret was fitted with a special collar, *above,* to help track animals in the wild.

Four reasons why people protect animals

1. For their beauty. Each animal is different from every other and adds to the beauty of nature.
2. For their economic value. Limited hunting of wild animals provides fur and food. Tourists who visit protected areas to see animals in the wild also bring in money.
3. For their scientific value. Wildlife study adds to knowledge of how animals grow and how they live in their environment.
4. For their survival value. Each animal helps maintain the balance of nature. The loss of any species may threaten the survival of many others.

Comparative speeds of animals

The speeds of animals vary greatly. Birds are the fastest of all animals, with flying speeds of more than 200 miles (320 kilometers) per hour. The speediest land animals outstrip the fastest water animals. Many of the figures given in the table below are estimates because scientists have difficulty measuring the speeds of wild animals. Powerful hind legs make the frog a champion jumper on land, *above,* and an expert swimmer when in the water.

made up mostly of skin stretched over long finger bones. Muscles in the wings raise and lower them.

Birds have powerful muscles attached to their wings and breastbone. Bird wings are covered with feathers, which also aid in flight.

Some animals, including flying squirrels and flying lemurs, can glide but not fly. Such animals jump from trees or mountains. They have big feet or folds of skin that spread out to serve as "wings" for gliding.

Fins, tails, and flippers. Many types of animals swim in fresh or salt water. Fish have well-developed tails and fins. Most fish swim by bending their powerful, muscular tail from side to side. Fins on the top, bottom, and sides of fish are used to maintain balance and to maneuver in tight areas. Dolphins, porpoises, and whales swim by moving their massive tails up and down rather than side to side. Turtles swim by paddling with their webbed feet or their flippers.

Jellyfish and squids swim by jet propulsion. When a jellyfish pushes water out from under its body, it is thrust in the opposite direction. A squid takes water into its body cavity and then squirts the water out through a small opening called a *funnel.* This action repeated many times pushes the squid forward.

A number of species of birds can swim. Some ducks and gulls paddle on the surface of the water using their webbed feet as oars. Torrent ducks and loons dive underwater, where they swim by kicking their feet. Penguins use their feet and their wings to swim.

Adaptations for eating

All animals need food to survive. Animals eat plants, other animals, or both plants and other animals. Animals that eat plants are called *herbivores.* Zebras, cows, and moose are herbivores. Animals that eat other animals are called *carnivores* or *meat-eaters.* Dogs, lions, and sharks are carnivores. Animals that eat both plants and animals are known as *omnivores.* Bears are omnivores.

Biologists describe the relationships between animals in a habitat and the foods they eat as a *food chain.* Technically, a food chain involves the flow of energy from the sun to green plants to animal consumers. For example, a simple food chain in a meadow links the grasses, the deer that eat the grasses, and the wolves that eat the deer. Sometimes, many kinds of animals and plants are involved in complex networks of food chains. Such networks are called *food webs.*

Most animals eat a variety of foods. For example, pigeons eat fruits, grains, and nuts, and they sometimes feed on insects, snails, and worms.

Some animals eat only a few foods. A snail called a cone shell preys only on a single species of marine worm. Several kinds of snakes eat only slugs or other snails. Hummingbirds and honey possums live on the nectar of flowers. A sapsucker drills holes in trees and eats the sap that flows from the holes. The koala of Australia dines only on the leaves of eucalyptus trees.

Filtering mechanisms. Huge numbers of tiny organisms called plankton float or swim slowly near the surface of oceans, lakes, and other bodies of water. Plankton make up a part of an important food chain in the ocean. Plankton are too small to be captured individually by animals that feed on them. Some animals, such as barnacles, sweep water past themselves while straining out the tiny plankton, which are thereby captured. This process is called *filter feeding.*

© François Gohier

A gray whale filters food from water by squeezing the water out of its mouth through thin plates called *baleen.*

E. R. Degginger

A snake swallows food whole. It has loose jaws that enable it to swallow eggs or animals much larger than its own head.

Alan Root Okapia, Photo Researchers

A lion has long, razor-sharp *canine* (pointed) teeth for killing and tearing such prey as antelope and zebras. It does not have teeth for chewing, however. It swallows its food in chunks.

Baleen whales are probably the best-known filter feeders. These animals, which do not have teeth, feed by gulping huge mouthfuls of water containing plankton, small fish, and other marine organisms. They then force the water out of their mouths through a series of strainers called *baleen.* The food is captured on the baleen and then swallowed. A baleen whale can consume as much as 4 tons (3.6 metric tons) of food a day.

Teeth and jaws. A large number of animals eat food that they need to tear into pieces small enough to be swallowed and digested easily. Teeth and jaws are adaptations for tearing food. Teeth may also be used to kill prey.

Teeth are adapted for the particular type of food an animal eats. Deer, giraffes, and other herbivores have teeth with broad surfaces for grinding grasses and plants into small bits. The powerful front teeth of beavers enable these animals to cut down trees for food and shelter. Lions have razor-sharp *canine* (pointed) teeth for killing and then tearing prey.

Birds have bills that are adapted for certain types of feeding. A hawk has a sharp, hooked beak for tearing prey. A woodpecker uses its long, pointed bill to drill into the bark of trees to find insects.

Insects have jaws and movable mouthparts that act like teeth. The jaws of grasshoppers are adapted for cutting and chewing plants. Mosquitoes have needle-shaped mouthparts for piercing skin and sucking blood.

Adaptations for breathing

Most animals need a continuous supply of oxygen to survive. The entire process of obtaining and using oxygen is called *respiration.* That part of the process that involves how an animal takes oxygen from its environment and gives off carbon dioxide is known as *breathing.* This section focuses on breathing. For a complete description of how oxygen flows to various cells of an animal's body and how it is used by those cells, see **Respiration.**

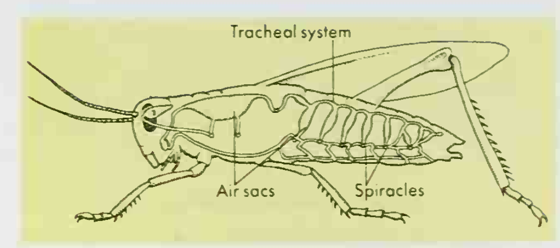
The way that animals breathe depends on where they live. Land animals get oxygen from the air. Aquatic animals obtain oxygen from water.

Many land animals have lungs for breathing. As blood flows through the lungs, it picks up oxygen from the air

Oxford Scientific Films from Animals Animals

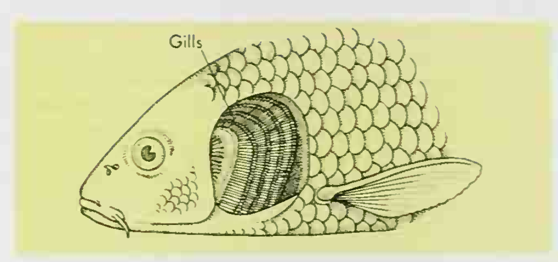
A water spider breathes underwater by means of large air bubbles held close to its body. Small bubbles of air trapped by the spider's hairlike body parts help supply extra air.

and releases carbon dioxide. The blood then carries oxygen to the rest of the body. See **Lung**.



Many aquatic organisms, such as fish and tadpoles, use gills to obtain oxygen that is dissolved in water. Some animals pump water across their gills to increase the efficiency of breathing. Sharks do this by swimming continuously.

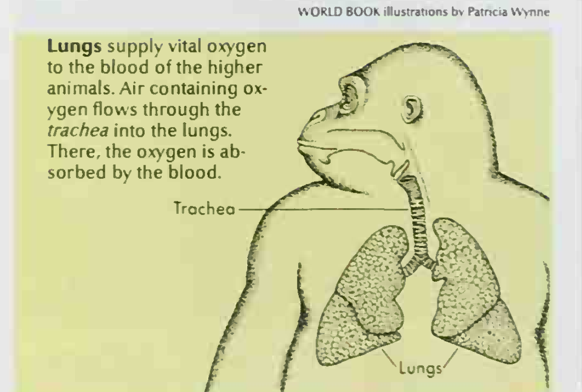
Tiny tubes called *tracheae* allow insects to breathe in air. Tracheae branch throughout an insect's body. They open to the outside air through holes called *spiracles*. When air enters the tracheae, oxygen is carried to every cell in the body.



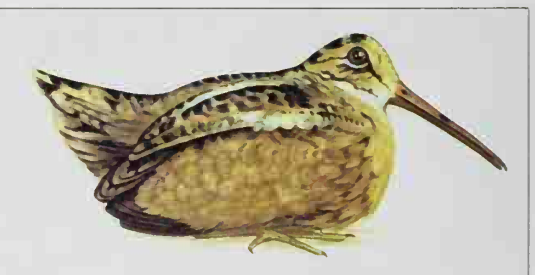
Some animals that live in damp environments have unusual ways of breathing. For example, some small salamanders have no lungs or gills. They breathe through their moist skin.

Adaptations for sensing the environment

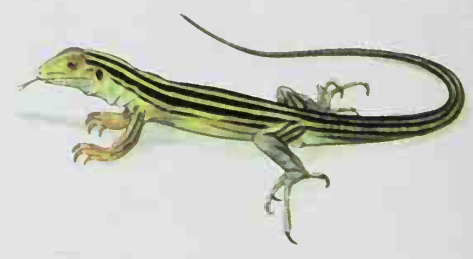
Most kinds of animals have special body parts that respond to changes in the animal's environment. Such a



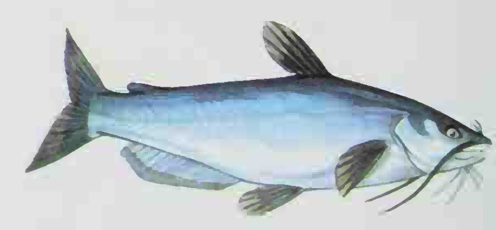
Spiracles are openings on the outside of an insect's body. Air enters the body through these openings and flows into air sacs. A *tracheal* (air tube) system distributes the air.



Gills are the breathing organs of most fish. The thin tissues of the gills absorb oxygen from the water. A fish gulps in water, and then forces it out through the gill openings.

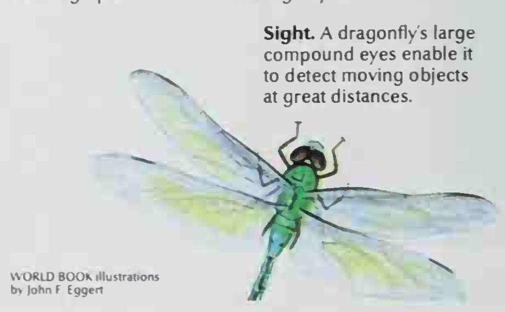


WORLD BOOK illustrations by Patricia Wynne



Lungs supply vital oxygen to the blood of the higher animals. Air containing oxygen flows through the *trachea* into the lungs. There, the oxygen is absorbed by the blood.

Touch. Woodcocks and many other birds can use the tips of their beaks to locate worms underground.



Smell. The forked tongues of snakes and some lizards are used to smell as well as to touch.

Taste. Catfish and certain other fish have cells called *taste buds* in the skin that covers their bodies.

Hearing. Bats navigate by the echoes that result from their high-pitched sounds striking objects.

Sight. A dragonfly's large compound eyes enable it to detect moving objects at great distances.

WORLD BOOK illustrations by John F. Eggert

A table of animal intelligence

Many animals can learn to do some tricks if they are carefully trained. But the ability to do tricks is not a sign of intelligence. Even fleas can be trained as circus performers.

Scientists measure the intelligence of animals by giving them problems to solve and by studying their behavior. In the past, most animals were studied in isolation from other animals. They were tested for how they performed tasks when given food as a reward.

Today, however, many studies of animal intelligence focus on animals in group settings. Such research concentrates on the intelligence animals use in their dealing with others of their kind and in solving group problems. Scientists believe this *social intelligence* may be closely related to the development of language skills. The ability to use language represents a high degree of intelligence.

The following table provides information on the intelligence of a number of types of animals, based on various scientific studies.

Apes and monkeys have the most humanlike intelligence. Chimpanzees seem to be the most advanced. They can make tools, plan complicated searches for food, and even count. They can also communicate by means of symbols. For example, they may use certain gestures to symbolize particular objects, actions, or states of being.

Large aquatic mammals, such as dolphins, whales, and sea lions, have brains much like those of human beings. They are capable of learning symbolic communication that may have properties like those of language. For example, dolphins seem to recognize differences in meaning based on the order in which the symbols are presented.

Carnivorous mammals in the cat and dog families show learning ability as good as, or better than, all animals except apes, some monkeys, and large aquatic mammals. Lions, tigers, and wolves probably can learn more rapidly than domesticated cats or dogs can.

Hoofed animals. Elephants and pigs are the best problem solvers among the hoofed animals.

Rodents are generally good at solving problems that involve finding their way through complicated pathways.

Birds, such as the raven and the pigeon, can solve simple counting problems. Parrots can learn to say human words and use them meaningfully in naming and counting objects.

Amphibians and reptiles are difficult to test, but alligators, crocodiles, turtles, and large monitor lizards may rival mammals and birds in locating sources of food and in some other forms of nonsocial learning.

Fish. Salmon and some other kinds of fish can remember odors for as long as several years. Sharks have brains as large as those of some birds and mammals. They have keen senses, and they are surprisingly clever at finding food and avoiding danger.

Animals without backbones often seem to learn very little. But some have remarkable and specialized abilities involving communication, food, and place learning. Many scientists consider octopuses to have the most complex brains of all the invertebrates. Octopuses learn rapidly and have distinct personalities.

---

stimulus (change) might come from an odor, a sight, a sound, a taste, or a touch. The simplest kinds of animals, such as sponges, have no special body parts and react to stimuli with their body cells. Animals with more complex physical structures, especially vertebrates, have highly developed organs for reacting to stimuli. These organs are described in the articles on **Brain** and **Nervous system.**

Some simple animals, such as hydras, react to stimuli with special cells. These sensory cells are scattered among the outermost cells of the body. The reactions of most other kinds of animals depend largely on one or more of the major senses. These senses are sight, hearing, smell, taste, and touch. See **Senses.**

Some senses are more important to one kind of animal than to another. Most birds cannot find food if they cannot see it. Hearing is vital to bats. If the ears of a bat are covered, the animal will crash into objects when it tries to fly. A keen sense of smell enables dogs and wolves to find food, follow trails, and recognize danger. Taste is highly important to many insects. The butterfly finds its food by sensing the sweetness of flowers with its feet. A cat's long whiskers serve as touch organs. They enable the cat to feel its way through underbrush and avoid bumping into objects.

A number of animals have special senses. A rattlesnake has *pit organs* on the side of its face that sense heat. These organs enable the snake to tell if a mouse or some other warm-blooded prey is nearby, even in total darkness. Many scientists believe that some birds and insects can detect the direction of the earth's magnetic field. This ability may help these animals navigate.

How animals protect themselves

The world of an animal is filled with danger from enemies. This section describes some of the many ways animals protect themselves from such danger.

Hiding in a safe place. The best protection against a predator is to avoid being seen by it. Many animals rest or sleep in a safe hiding place. Some desert toads crawl down a crack in the mud. A cricket hides under a large rock or under the loose bark of a tree. Worms and moles dig underground tunnels.

Many species, such as rabbits, leave their nests mainly or only at night, when they are harder for enemies to spot. Other species become active for only short periods so they are not exposed to predators for long.

Camouflage. Many animals are difficult for enemies to see because they resemble their surroundings. The various ways animals blend with their surroundings are called *camouflage.* For camouflage to be effective, the animals must remain motionless or nearly so.

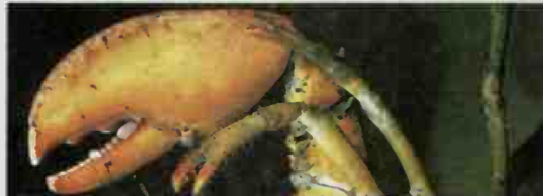
Protective coloration is coloring that helps animals to hide. A dark moth lying against the brown or black bark of a tree is hard to see. However, that same moth would be clearly visible if it sat on a green leaf.

A number of animals can change their colors and thus remain camouflaged even when moving among backgrounds that have different colors. The chameleon, a type of lizard, is green when surrounded by leaves but

Animals defend themselves from enemies by a variety of means. Some use such weapons as sharp teeth and claws. Others simply run away from attackers. In some cases, the weapons an animal uses for defense are the same ones it uses to capture prey.

Leonard Lee Rue III

The armadillo's armor protects the animal from harm. The bony plates of the armor fit together so well that the armadillo can roll up tightly into a ball when an enemy comes near.



E. R. Degginger

Speed is the impala's main defense. An impala can run as fast as 50 miles (80 kilometers) per hour in bounding leaps.

E. R. Degginger

Sharp quills help protect a porcupine from attack. When touched, the barbed quills come off the porcupine and hook into the attacker's flesh, where they can cause painful wounds.

Zig Leszczynski, Animals Animals

A lobster's claws are powerful weapons. The animal uses its claws to seize crabs, fish, snails, and other prey. The strong, toothed claws then crush the prey and tear it into pieces.

Ted Levin, Animals Animals

Sharp claws called *talons* are used by owls to defend their nests from intruders and to capture prey. A saw-whet owl spreads its talons to catch a mouse, *above.*

Breck Kent, Animals Animals

Pierre Labout, Jacana

Mimicry helps many animals avoid predators. Some animals *mimic* (resemble) other objects in their environment or other animals. The wings of a dead-leaf mantis, *above,* resemble leaves. Some robber flies look so much like a bumble bee that enemies often avoid them. The razor fish has a long, slender body that resembles the thin leaves of a sea plant. A treehopper on the stem of a rosebush looks so much like a thorn that birds often overlook the insect.

turns brown when moving slowly on bark or on the ground. The ptarmigan, an arctic bird, is brown in summer but becomes white in winter, when snow covers the ground.

Mimicry helps many animals avoid predators. Some animals *mimic* (resemble) other objects in their environment. For example, many green insects are shaped like leaves. Some caterpillars look like lizards or bird droppings. Walkingstick insects are shaped and colored like twigs. Anglerfish resemble rocks on the ocean floor.

Batesian mimicry is a form of mimicry in which an otherwise harmless animal strongly mimics an offensive animal. This type of mimicry was named after the English naturalist Henry W. Bates, who studied it in the 1800's. Bates observed that some harmless species have coloring and behavior that make them look like a dangerous or bad-tasting animal. A predator spotting such a species may mistake it for the undesirable animal and leave it alone. For example, viceroy butterflies are believed to be tasty to birds. But birds rarely attack them because they look like foul-tasting monarch butterflies. See **Protective coloration**.

Escaping by flight. Many animals run away from an attacker. Antelope sprint away at high speed when charged by a lion or a cheetah. Many animals stay near safe places, such as burrows, and run to them if attacked. The octopus squirts a black inky fluid to conceal itself and then quickly swims for safety.

Armor. Some species have a hard shell or covering that is used as armor against predators. Clams pull back into their shells when a predator approaches. Many turtles can pull in their head, legs, and tail when attacked. Armadillos and pangolins are covered by hard, bony plates. When frightened, these animals roll into a tight ball that is difficult for enemies to penetrate.

Playing dead. A few species sometimes fool predators by lying motionless and appearing to be dead. If the predator does not deliver a killing blow or bite, then the animal may have a chance to escape. A threatened opossum goes limp. The hognose snake flips onto its back when a predator approaches.

Giving up a body part. Many animals break off a nonessential part of their body when attacked. The glass lizard breaks off its tail, which flops about and attracts the attention of the predator. While the attacker struggles with the tail, the lizard escapes. In most cases, the lost body part grows back quickly.

Fighting. Many animals have special weapons for fighting predators. The sharp hooves of a moose or the claws of an ostrich can rip open an enemy. Porcupines have long, sharp quills on their back, sides, and tail. These animals strike attackers with their quilled tails. The quills come out easily and stick in the attackers. Bees and wasps sting animals that approach their nests.

Chemical defenses. A number of animals use special chemicals for defense. Hagfish and one kind of starfish give off huge quantities of slime when disturbed. The bombardier beetle squirts irritating chemicals at an enemy. Some cobras spit blinding venom at the eyes of attackers. Skunks spray foul-smelling chemicals. Birds from New Guinea called hooded pitohuis have poisonous feathers and skin.

How animals reproduce

All types of animals reproduce. Many animals have special organs that are used in reproduction. These organs are called *gonads*. Some simple animals do not have gonads, but they are still able to reproduce. The various methods used by living things to reproduce are described in detail in the **Reproduction** article.

There are two general forms of animal reproduction: (1) *asexual reproduction* and (2) *sexual reproduction*. In asexual reproduction, only one parent produces the offspring. In sexual reproduction, two parents of opposite sexes are needed to produce the offspring. Many of the simplest animals, including sponges, sea anemones, and some flatworms, reproduce asexually most of the time. Sometimes, they reproduce sexually as well. Most other kinds of animals reproduce only sexually.

Asexual reproduction. Planarians and some other flatworms can reproduce by *fragmentation,* the division of the body into two or more pieces. When a planarian reproduces asexually, it typically divides into two sections, one with the head and the other with the tail. Each section then grows the parts that are missing and becomes a complete new individual.

Hydras and some sea anemones reproduce by *budding*. The animal produces small projections, called *buds,* from its side. These buds develop into miniature copies of the parent. The buds eventually detach from the parent, and the individuals produced by budding grow to be as large as their parents. Then they can put forth buds to create their own offspring.

Sexual reproduction. Most animals that reproduce only sexually do so with special sex cells known as *gametes*. Female sex cells are called *eggs* and are produced in the female gonads, the *ovaries*. The male sex cells are known as *sperm* and are made in the male gonads, the *testes*. Sperm are much smaller than eggs and have a tail that enables them to swim toward eggs. When a sperm cell unites with an egg cell, a new animal starts to form. The process in which the sperm unites with the egg is called *fertilization*.

External fertilization occurs outside an animal's body. Many aquatic animals reproduce sexually without ever meeting. Female sea urchins release millions of egg cells directly into the water. About the same time, the males release their sperm. The sperm swim through the water, and some unite with eggs, leading to fertilization. The fertilized eggs develop into swimming offspring, which are called *larvae*. The larvae grow and eventually sink to the bottom of the sea, where they become small sea urchins with bodies similar to those of their parents.

Internal fertilization occurs within an animal's body. If gametes are released on land, they dry up and die. Consequently, land-dwelling animals that reproduce sexually have developed ways for fertilization to take place inside their bodies.

Animals mate in many ways. Males of such species as snakes, lizards, birds, and mammals mate by releasing sperm directly into an opening in the female's body. Fertilization occurs in the female's reproductive organs.

Male salamanders do not release sperm directly into the female's body. Instead, they deposit a packet of sperm at the bottom of a stream or pond. When the female passes over the sperm, she draws them into an opening in her body that leads to her reproductive organs. Several other animals, including mites and scorpions, mate in a manner similar to that of salamanders. Males deposit packets of sperm on the ground, which are then picked up by females.

In almost all mammals and some reptiles, the *embryo* (undeveloped animal) grows inside the female's body after fertilization. However, in birds and some reptiles, the embryo develops outside the body. The female lays an egg in which the embryo develops. See Fertilization.

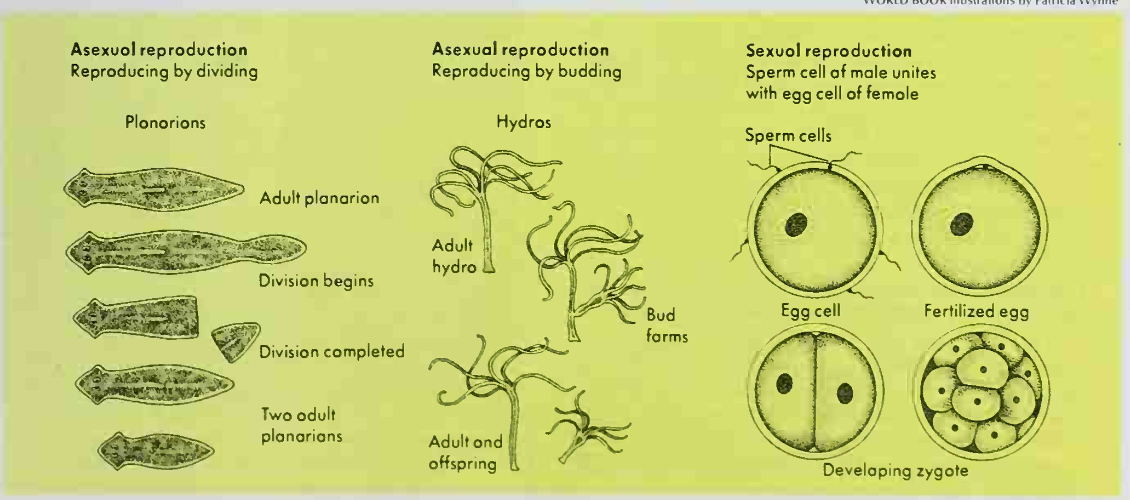
Courtship behavior consists of actions that help animals find and choose suitable mates. This behavior tends to follow a specific pattern according to species. As a result, courtship behavior helps ensure that animals mate with members of their own species. If two different species mate, they may not produce young, or their offspring may be unhealthy or unable to reproduce. Such courtship behaviors as singing and displaying colors help animals recognize their own species.

Animal mates find each other in a number of ways. Female birds are attracted to the beautiful songs and bright feathers of males. Female grasshoppers, cicadas, bullfrogs, and toads also are attracted to the calls made by males of their species. Female silkworm moths release into the air a perfumelike chemical called a *pheromone* to attract males from as far away as several miles or kilometers. At certain times of the year, female dogs give off a pheromone that attracts male dogs. Female fireflies watch for male fireflies that flash their lights in a certain rhythmic pattern. Male fence lizards bob their heads rhythmically when a female approaches. Siamese fightingfish perform a complicated courtship dance, followed by the release of eggs and sperm into the water.

Some animals choose particular mates. The female anole lizard typically prefers to mate with the largest male. The peacock spreads his fantastic tail feathers, hoping to coax a peahen into becoming his mate. Peahens choose males with many spots on their tail feathers. Male birds of paradise gather in a tree. When a female appears, the brilliantly colored males strut and dance to show off their bright feathers. If a female chooses to watch this display, she will usually mate with the male that has the brightest colors.

Male bowerbirds build chambers or runways, called *bowers,* made of sticks or other material. They decorate these structures with brightly colored stones, bones, or other objects. The male dances and bows in front of his bower, hoping that a passing female will accept him as a mate. If one does, she enters the bower with him, and they mate there.

Some male animals give food to possible mates. A male tern catches a fish and places it into the mouth of



Animal reproduction

Animal	Approximate gestation period	Typical number of newborn
Alligator (American)	9 weeks*	50-60†
Bat (common vampire)	210 days	1
Cat	65 days	4
Dog	9 weeks	1-10
Elephant	21-22 months	1
Frog (bullfrog)	5-20 days*	20,000†
Gerbil	19-21 days	4-7
Guinea pig	68 days	1-5
Hamster (golden)	16 days	6-9
Horse	332-342 days	1
Lion	100-119 days	3-4
Monkey (spider)	226-232 days	1
Mouse (field)	21-23 days	5-6
Rabbit (cottontail)	25-40 days	3-6
Robin, American	12-14 days*	4†
Sheep	150-180 days	1-2
Squirrel (red)	33-35 days	4-6
Tiger	104-106 days	2-3

*Approximate incubation period
†Approximate number of eggs a female lays. Not all of them hatch into newborns

Animal reproduction Animal reproduction may be *asexual* or *sexual.* Planarians and hydras can reproduce asexually. Planarians, *left,* split into two worms. Hydras, *middle,* grow from projections called *buds* on the parent. In sexual reproduction, *right,* a sperm cell fertilizes an egg, which develops into a new animal.

WORLD BOOK illustrations by Patricia Wynne

Frans Lanting, Photo Researchers

The courtship ritual of the albatross involves an elaborate dance between a male and female, *left,* before they mate. Through courtship rituals, animals can identify members of their own species for mating. In some cases, such rituals help them choose specific mates.

the female he wants for his mate. A male dance fly brings a dead insect to a female. She eats the insect while mating with the male. A male that does not bring a dead insect risks being eaten by the female.

Mating is dangerous for some male spiders and insects. Male black widow spiders are sometimes eaten by females after mating. A female praying mantis may pounce unexpectedly on a male in her vicinity. Sometimes, she mates with a male and then eats him.

Regeneration. Some kinds of animals, mostly simple animals, can replace lost body parts by *regeneration.* If a sponge is broken into small pieces, some of the fragments will grow into new sponges. Earthworms and their marine relatives can regenerate their heads or tails if those parts are broken off. Crabs and lobsters can grow new claws. Sea cucumbers sometimes throw out their intestines and other internal body parts to distract attackers. New parts grow back quickly.

Even some vertebrates can regenerate parts of their bodies. A salamander that loses a leg will grow a new one. Many salamanders can break off their tails to escape the grip of an enemy. These animals soon grow new tails. Mammals can regenerate hair, nails, and some other body tissues.

How animals raise their young

The newborn young of many species need no care from their parents. Even from birth, they can move about and find food on their own. The young of other species need parental care for some time after birth. One or both parents provide them with food and protection until they are old enough to manage for themselves.

Most kinds of animals never see their parents. For example, clams and many other invertebrates release their eggs and sperm into the water, where fertilization takes place. Carried around by ocean currents, the young of these animals may travel far from where their parents live. The female leatherback turtle swims thousands of miles or kilometers in the ocean to tropical beaches. She then digs a hole on the beach and lays her eggs. The eggs hatch in the warm sand after the female has returned to the sea.

Providing food is one of the main ways animals care for their young. Even females who never see their offspring provide them with food. The female's eggs contain yolk and other nourishing substances that serve as food for the developing embryos. Female sea urchins and herring produce vast numbers of small eggs, each of which has little yolk. Offspring from these eggs are extremely tiny when they hatch and must find their own food to grow. Their chance for survival is relatively small. Female birds, on the other hand, lay only a few eggs, each with large amounts of yolk. Offspring from these eggs are relatively large and have a higher chance of survival.

Some animals that do not see their offspring provide their young with food in addition to that in the egg. Many flies lay their eggs on rotting fruits, which supply the young flies with food. The female digger wasp lays her egg on a grasshopper that she has stung, paralyzed, and buried. After hatching, her offspring feeds on the grasshopper. The female dung beetle finds fresh *dung* (manure), rolls a piece into a ball, and then buries it. She lays her egg on the dung ball. After hatching, the young beetle feeds on the dung.

Mammals *nurse* their babies—that is, they feed them on the mother's milk. The nursing period lasts only a few weeks in mice, hares, and many other species. But among some larger mammals, such as elephants and rhinoceroses, the young may nurse several years before they are *weaned*—that is, taken off the mother's milk.

Incubation. In many species, the mother and sometimes the father remain with their eggs and young. Birds incubate their eggs by sitting on them in a nest. Incubation keeps the eggs warm and helps the embryo inside to develop quickly into a young bird. After the eggs hatch, the parents may make many hunting trips each

day, trying to catch enough insects to feed the hungry *nestlings* (young birds). When the young are old enough to hunt, they leave the nest and fly away.

Among many species of birds, including pigeons and starlings, the parents take turns incubating the eggs. Among ducks, geese, and some other birds, the females are the only incubators. In most species of hornbills, the

Names of animals and their young

Animal	Male	Female	Young
Ant		queen	antling
Antelope	bull	doe	kid
Bear	boar	sow	cub

*There are numerous alternate names for this animal and its young.

Karl W. Kenyon, NAS

Fur seals start life in a group with many other pups and their mothers. Mother seals divide their time between eating at sea and nursing their pups on land. Each mother seal nurses and tends only her own young.

female even imprisons herself inside a walled-up nest chamber to incubate eggs. The male passes food to the female through a tiny slit in the wall. In a few species of birds, the male does all the incubating. For example, a female emperor penguin lays a single egg, which the male then incubates on top of his toes. He tucks his toes and the egg under the fluffy feathers of his belly. When the egg hatches, the little penguin stays warm and grows in this cozy "nest."

Female pythons also incubate their eggs. They produce the heat to warm their eggs by twitching their muscles, much as people do when shivering. After the baby pythons hatch, they must find food and shelter on their own.

Providing shelter. Some species provide shelter for their young. A female lizard may lay her eggs in an underground nest, where they are hidden from predators. The huge nests of sociable weavers, a type of African bird, protect the baby birds from bad weather and enemies. Some frogs and fish build nests for their eggs and young. A few tropical frogs carry their tadpoles around on their backs until they find a safe pool of water for the young frogs.

Parents sometimes provide shelter for their offspring within their own bodies. The male seahorse carries the female's eggs in a pouch. When the young seahorses hatch, the male releases them from the pouch. Female kangaroos, koalas, opossums, wallabies, and other *marsupials* give birth to tiny, poorly developed offspring. The babies mature in a pouch on the mother's abdomen. There, they nurse and are protected by the mother. One kind of Australian frog swallows her eggs into her stomach, where they develop. After the eggs hatch, the female opens her mouth, and tadpoles and small froglets come out.

Providing protection. Parents often protect their young from enemies. A male stickleback fish will attack any predatory fish or insect that approaches its young. A female scorpion carries her babies on her back and defends them with the poisonous sting on the tip of her long tail. Female crocodiles guard their nests and will fight any predator that comes near. As young crocodiles begin to hatch, they cry out, and the female helps them dig out of the nest. She then gently picks them up in her jaws and carries them to a nearby pond. A female bear will sometimes attack hikers who venture too close to her cubs. A female pet dog may attack even her owner if she fears that her puppies are threatened.

Names of groups of animals

Animal	Group	Animal	Group
Bear	sloth	**Lion**	pride

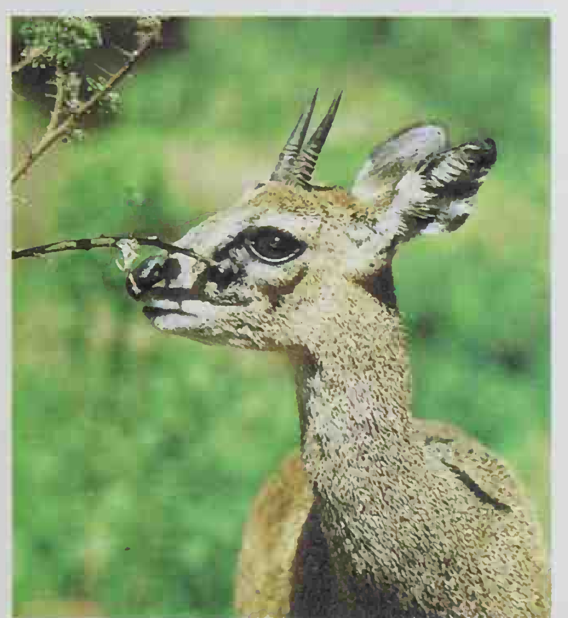
Goose (in flight)	skein	**Toad**	knot
(on land or		**Whale**	herd
in water)	gaggle		pod
Kangaroo	herd	**Wolf**	pack
	mob		

Group care. Some animals live together in groups of several families. As many as a hundred pairs of sociable weavers raise their chicks together in a large nest. Several female lions may care for their young cubs together. Naked mole rats live in underground colonies. One female produces offspring. Most of the other females help tend the young. Many monkeys and baboons live in small groups. All the adults in a group will work together to defend their young from an attacking leopard. When attacked by a wolf, a herd of musk oxen will protect their calves by placing them between adults.

Learning and play. Young animals may learn many things about the world from their parents. By watching what foods its parents eat and reject, a young animal can learn to recognize the kinds of foods that are safe. If young animals see their mother show fear of another type of animal or of certain locations, they learn to avoid those animals and places. Thus, they learn which types of animals, foods, and environments are safe and which are dangerous.

Many animals play while they are young. Lion cubs may try to pounce on the twitching tail of an adult lion. They also play with one another as though they were fighting. Such games help young animals develop coordination and strength. Play also helps them learn how to defend themselves and to fight effectively. In addition, it enables some animals to learn how to stalk and capture prey.

Animals' homes provide shelter from harsh weather or protection against enemies. Some animals have shelters that they use only once. Others make homes where they live for many years. However, a number of animals, such as fish that live in the ocean, spend their whole lives moving about. They never have homes.



A number of animals use caves, cracks in the ground, logs, plants, or rocks as temporary shelter. Garter snakes and many insects spend the night under rocks but leave this shelter the next day to hunt for food.

Some animals build their homes. Field mice collect dried grass and then construct a small nest under a protective log. Many birds and squirrels collect grass and twigs to build nests in the trees or on the ground. Gophers and moles dig burrows in the soil.

Home ranges. Most animals live within certain areas that form their *home range*. An animal's home range includes all the resources an animal needs to survive. By living within a specific area, an animal can learn where best to find food or shelter there.

The size of an animal's home range depends typically on the animal's size. Crickets and sea urchins have small home ranges. But elephants and lions may have home ranges that cover vast distances. Big animals require extensive home ranges to obtain the large amounts of food they need to survive.

Some animals defend their home ranges from other animals. A defended home range is called a *territory*. The song of a warbler, the hoot of an owl, or the roar of a lion warns other animals of their kind to stay away. Some animals use chemical warnings rather than sounds to ward off invaders from their own species. Intruders can easily smell the urine of wolves and the scent marks of cats and hyenas and know that a territory is already occupied. Often the intruder leaves without a

Meerkats live in colonies of up to 30 individuals. These burrowing animals of southern Africa leave their underground homes only during the day. Meerkats stand upright to watch for large birds that may attack them, *left.*

fight. Sometimes, however, fights break out over territory, resulting in injury or death.

Group living. Many animals live in groups. Some groups, such as herds of elephants, remain together for many years. Others are small families that come together only during the breeding season. A mother and father bird may cooperate in raising their nestlings but may separate when the young leave the nest.

Wolf packs and some other animal groups have a social order called a *dominance hierarchy.* In such groups, every member has a certain rank in the hierarchy. High-ranking members are called *dominant individuals,* and low-ranking ones are known as *subordinate individuals.* The dominant individuals have first choice of such resources as food and water. They also have their pick of mates. See **Dominance.**

Some groups are large and complex. Ants, bees, and termites live in huge colonies that consist of many thousands or even millions of individuals. The individuals in these colonies often have specific tasks. With honey bees, the *queen bee* is responsible for producing eggs. *Workers* search for pollen, make honey, and feed and care for the queen and her offspring. *Drones* do little but fertilize the queen's eggs.

Fish may form large schools in the open ocean. Herring schools may consist of hundreds of millions of fish.

Animal migration

Why animals migrate. The environment of some animals becomes extremely harsh at certain times of the year. In winter, for example, high mountains become bitterly cold. Snow and ice cover the peaks, and food becomes hard for animals to find. Some animals survive by hibernating. Others travel to places where the weather is milder and more food is available. The next spring, these animals return home. This type of regular round-trip journey is called a *migration.* Many animals that migrate live in the mountains or far from the equator. Migrating animals usually travel in large groups.

Animals migrate for other reasons than to escape cold weather. Some travel to favorite feeding areas or to special places to produce their young.

Animal travelers. Many birds make seasonal migrations. Some simply move short distances from the mountains to the valleys below. Others make remarkable long-distance journeys. In the fall, huge flocks of ducks and geese fly south for the winter. European white storks spend the spring and summer in northern Europe, where they breed and raise their young. They fly as far south as southern Africa for the winter.

The arctic tern is the champion long-distance traveler. Terns breed on islands in the Arctic Ocean. In late summer, they begin a long journey and fly all the way to Antarctica. They feed on the fish that are plentiful there before flying north to the Arctic to breed the following summer. A tern making this round trip may fly as many as 22,000 miles (35,400 kilometers).

Humpback whales and blue whales also make long

WORLD BOOK map

Repeated round-trip migrations are made by the European white stork. This bird lives in northern Europe in spring and summer. Every fall it flies to Africa over one of the routes on the map. The white stork returns to Europe by the same route.

migrations. They spend the summer in polar oceans, which have plentiful food. In the autumn, they swim toward the equator until they reach the warm tropical seas. There, the females that are pregnant give birth. Others mate and then give birth the next year. The warm waters provide a comfortable environment for the babies. The whales spend the winter in the tropics before returning to the polar feeding area in the spring.

Monarch butterflies and many other insects also migrate. When winter approaches, swarms of monarch butterflies travel from Canada and the northern United States to California and Florida. Some even fly as far south as southern Mexico. The butterflies begin the return trip in the spring, but few of the adults that flew south live long enough to complete it. Female monarchs lay eggs along the way back. The offspring, after maturing, continue the northward journey.

Some animals travel long distances to find a breeding site. The green sea turtle feeds along the east coast of South America. It then swims 1,200 miles (1,900 kilometers) of open ocean to breed on Ascension Island, a small island in the middle of the Atlantic Ocean. When the baby turtles hatch, they swim to South America, where they may remain for many years. When they are mature, they swim back to Ascension Island and breed.

Most salmon live for years in ocean waters. When the time comes for them to *spawn* (lay their eggs), they travel thousands of miles or kilometers. The salmon swim to inland waters, where they produce their young. The adult salmon die before the young hatch.

Dangers of migration. Migrating animals may face a number of dangers, including new predators, during their long journeys. Some dangers come from human beings. For example, the fences that farmers use to corral their livestock prevent antelope from making their seasonal migrations. Farmers often shoot migrating animals that stop to feed on their crops. The draining of wetlands makes it harder for ducks and geese to find a safe place to rest and feed during migration. Some winter feeding areas are also being destroyed.

The origin and development of animals

Most scientists believe that all plant and animal species probably developed from a single form of life that arose about $3\frac{1}{2}$ billion years ago. The basic life form gradually changed so that through the centuries, millions of kinds of animals have come into being. Some kinds are still alive. Others are *extinct* (no longer living). All animals, whether living or extinct, are related to one another.

This set of ideas about how species change over time is called the theory of evolution. The theory is supported by a vast amount of evidence from many fields, and most scientists consider the occurrence of evolution to be a scientific fact. However, many people reject the concept of evolution because it conflicts with their religious beliefs. The Biblical account of the Creation, for example, says that God took only a few days to create all living things essentially as they exist today.

This section uses evolutionary theory as the basis of a discussion of when some animals originated and how species change. For a discussion of religion and evolution and for more information on evolution, see Evolution. For more information on creationism, see **Creationism.**

When animals appeared on the earth. Most scientists believe that the earth formed as a planet at least $4\frac{1}{2}$ billion years ago. The first life forms were simple, single-celled organisms that appeared about 1 billion years later. More complex animals and plants gradually evolved from these simple organisms. Many groups of invertebrates arose about 650 million years ago. The first vertebrates—fish—developed about 500 million years ago, and the first mammals appeared more than 200 million years ago.

Another way of looking at these times is to imagine the history of life on the earth in terms of a single year. Start with the formation of the earth on New Year's Day, January 1. Bacteria, the first types of living things, would not appear until March 22. Many invertebrates would not show up until November 9. Fish would evolve from their invertebrate ancestors about November 20. Mammals would appear on December 16. Monkeys and apes would not be found until December 28. Human beings would appear only a few minutes before the end of the year, on December 31.

For more information on when various types of animals appeared on the earth, see Earth (History of the earth).

How new species are formed. Scientists consider groups of animals to represent distinct species when they become so different that they cannot produce fertile offspring together. Imagine a group of birds that lived only on one island. Then imagine that a few individuals got lost in a storm and landed on a different island. The two groups, now separated from each other, may gradually develop different traits as they adapt to different environments. If they become dissimilar enough, they cannot produce fertile offspring if they mate. They are then two separate species. This process can repeat itself many times over many millions of years, resulting in great numbers of species.

How species change. The individuals of any given species are not the same. Some individuals are larger, some are darker, some tolerate heat better, and some are stronger. Some individuals have traits that make them better able than others of their species to survive and reproduce in their environment. Over long periods, those animals will produce more young that survive than will individuals with less desirable traits. The offspring of the better-suited species will probably share some of the desirable traits of their parents. For example, dark moths will be well hidden in a shady forest. More of their offspring will probably survive than will those of lighter moths, which may be easily seen and eaten by hungry predators. In the next generation, more moths in the forest will be dark. This process, which causes the traits of animal groups in nature to change through time, is called *natural selection.* See **Natural selection.**

Why species become extinct. Scientists estimate that, left to natural processes, most species of animals

live 1 million to 10 million years before becoming extinct. Natural causes that lead to the extinction of animals include drastic changes in climate and failure of a species to compete with other animals for food. For example, the dinosaurs died out rather suddenly about 65 million years ago. Many scientists believe that these huge reptiles became extinct because of a rapid change in climate and the dinosaurs' inability to survive in it.

Some human activities also cause animals to become extinct. Such activities are discussed in the next section of this article. For more information on why animals become extinct, see **Extinct animal.**

The future of animals

Some scientists believe that we are living in a period of mass extinction. In the United States alone, about 40 species of birds, 35 species of mammals, and 25 other species of animals have become extinct during the last 200 years. Many of these species became extinct as a result of human activities. Hundreds of other species in the United States have become *endangered* (in danger of going extinct). Today, however, more and more people are working to preserve the variety of animal life for future generations.

How human beings endanger animals

Destruction of habitat. When people build cities or cut down forests to obtain wood or to clear land for farming, they destroy the habitats that animals need to survive. For example, grizzly bears and mountain lions once roamed freely where the city of San Francisco now stands. But a wild grizzly bear or mountain lion could not survive in San Francisco today.

The habitats of animals in tropical forests are particularly threatened today. People are rapidly cutting down these forests to obtain such valuable hardwoods as mahogany and teak. They are also clearing the land to plant crops. However, soils in such areas are not especially fertile, and farms there produce crops for only a few years. To continue farming in such areas, people have to keep cutting down more of the forests to create new farmland. By the early 1990's, about two-fifths of the world's tropical forests had already been destroyed.

Many scientists and other people are especially concerned about the destruction of tropical forests. They point out that these forests have more *biodiversity*—that is, a greater variety of plant and animal species—than any other place. One square mile (2.6 square kilometers) of forest in South America may have more species of birds and insects than many countries do. In fact, biologists discovered a single tree in a tropical forest in Peru that supported 43 species of ants. That is as many species of ants as live in the entire United Kingdom.

Even though many types of plant and animal life can be found in one place in the tropics, the total range of many tropical species is extremely small. As a result, when a large area of forest is cleared, all the members of some species are killed.

Pollution. Various types of pollution can also destroy animals and their habitats. Agricultural chemicals and industrial wastes sometimes drain into ponds and streams and kill the plants and animals there. Air pollution produced by factories that burn such fossil fuels as coal and oil has seriously damaged forests and wildlife. *Acid rain*—rainfall with a high concentration of sulfuric and nitric acids due to air pollution—kills fish and other animals.

An increase in carbon dioxide in the atmosphere presents a long-term threat to animals and habitats. Many factories—as well as automobiles and power plants—release carbon dioxide into the air. Forest trees and plants help absorb this gas, but as more of them are cut down, carbon dioxide levels rise. Many scientists believe that higher amounts of carbon dioxide in the atmosphere speed up global warming caused by the phenomenon known as the *greenhouse effect.* A major global warmup could produce significant changes in the earth's climate. Such changes could destroy many kinds of plants and animals. See **Greenhouse effect.**

W. K. Fletcher, Photo Researchers

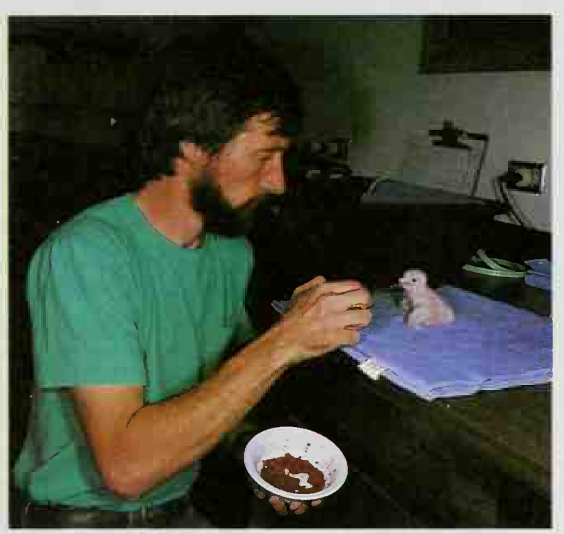
Destroying a forest results in the loss of habitat for many animal species. Animals that live in tropical forests are especially threatened today. People cut down these forests to obtain wood and fuel and to clear land for farms and cities. This photograph shows a logging operation in a tropical rain forest in Malaysia.

Introduction of new species into an area can sometimes have unexpected consequences. In the mid-1800's, for example, people introduced rabbits into the wild in Australia for sport. However, the rabbits had no natural enemies there, and their population grew quickly. Partly as a result of the rapid increase and spread of rabbits, rabbit-eared bandicoots, which are native to Australia, disappeared from some areas of the continent. The bandicoots had to compete with the rabbits for burrow space. The traps and poisons people set out for rabbits also killed bandicoots.

People may unintentionally cause new species to enter an area. Zebra mussels are shellfish that are native to the area around the Caspian Sea, which lies between Europe and Asia. They were first found in North America in 1988. Their larvae had been unintentionally released into the Great Lakes in *ballast water,* the water kept in the hold of a ship to keep the vessel stable. Today, the mussels are a major pest in North America. The explosive growth of zebra mussel populations may threaten the food supply of many species of fish and shellfish that are native to the Great Lakes. See **Zebra mussel.**

Hunting. Through the centuries, people have overhunted certain animals and caused them to become extinct. For example, prehistoric hunters probably helped make woolly mammoths and mastodons extinct.

Overhunting in the past 200 years has been especially destructive of animal life. It contributed to the extinction of such animals as the great auk, the passenger pigeon, and the Steller's sea cow.



Human population growth. The human population is growing rapidly. By the late 1990's, the world had almost 6 billion people—about five times as many as it had in 1850. Some experts predict that by 2050 the population will have about doubled from what it is now—to more than $11\frac{1}{2}$ billion people. Such a huge increase in the number of people on the planet would place additional pressure on natural habitats. People would need more land for food and housing. In addition, human industrial activities would probably increase to process the food and manufacture the goods the growing population would need. Many such activities cause pollution, which also can damage or destroy habitats.

For more information on why animals become endangered, see **Endangered species.** See also the special feature on *Endangered animals* that appears in this article.

How human beings protect animals

Since the late 1800's, people have become increasingly concerned about the world's vanishing wildlife. Such concerns have resulted in part from a growing awareness of the interconnectedness of species—the web of life. Greater numbers of people now recognize that the disappearance of large numbers of species threatens the survival of other living things, including human beings. People who help protect habitats and animals are called *conservationists.*

Protected areas. The United States and many other countries have created national parks, game reserves, and wildlife refuges. In these areas, habitats are protected from development and hunting is banned. Many conservationists believe that these areas may represent the last hope for saving some threatened species in the wild.

Stephen J. Krasemann, Nature Conservancy from Photo Researchers

People protect some animals by raising them in captivity. A peregrine falcon chick receives a meal, *above.* Peregrine falcons are rare or absent in many of their former habitats.

Yellowstone National Park is one of the largest wildlife preserves in the United States. Grizzly bears and bison roam the park freely, and bald eagles and trumpeter swans nest there. All these species are rare. The African elephant and black rhinoceros are protected in parks and reserves in the African savannas.

Laws. State and federal laws also protect wildlife in the United States. For example, under the Endangered Species Act of 1973, officials in the Department of the Interior keep an up-to-date list of species that are in danger of extinction. The act prohibits federal projects that would destroy the habitat of an endangered species. In 1982, the act was amended to require anyone who wants to develop or change a habitat occupied by an endangered species to show that the planned changes will not harm that species.

Federal and state agencies in the United States also determine the number of certain game animals that can be hunted and fished each season. If an animal starts to become rare, the agencies can reduce the number of that species that can be taken legally. The population of that species then has an opportunity to recover.

Breeding in captivity. Some species have become so rare that scientists believe the only hope of saving them is to breed them in captivity. For example, nearly all the California condors that are still alive are in zoos in the United States. A condor chick raised in captivity has a better chance of survival than one in nature does. As the number of condors grows, biologists are beginning to reintroduce a few birds back into the wild. Other endangered species being bred in captivity include the Arabian oryx and the whooping crane.

In spite of conservation efforts, the future of wildlife remains uncertain. The human population continues to grow. Forests and grasslands are still being destroyed. People continue to hunt African elephants, snow leopards, and other vanishing species. Air pollution, acid rain, and water pollution also still threaten the survival of wild species. Raymond B. Huey and W. Herbert Wilson, Jr.

A classification of the animal kingdom

Scientists classify animals chiefly according to the animals' ancestry. Those with a common ancestor nearer in time are more closely related than those who share an ancestor further back in time. Closely related animals share certain unique features. Scientists today arrange animals into 33 major groups called *phyla* (singular *phylum*). The classification below lists some of the phyla and some of the features of their members. It is arranged, roughly, from the smallest animals to the largest. However, sizes of animals within a phylum can vary greatly.

Phylum	Characteristics	Example
Rotifera (Rotifers or "wheel animals")	Rotifers live in lakes, rivers, streams, and the oceans. They have cylinder- or vase-shaped bodies. On their heads are circles of hairlike projections known as *cilia*. The largest rotifers are about $\frac{1}{10}$ inch (3 millimeters) long. About 2,000 species have been identified.	***Brachionus calyciflorus***
Bryozoa (Bryozoans)	Bryozoans live in water, and most form colonies. Some colonies are jellylike masses. Others form branchlike networks on water plants. Bryozoans have a boxlike or tube-shaped body that holds fluid. *Tentacles* (feelers) cluster on the head. About 5,000 species have been identified.	**Bowing ectoproct**
Cnidaria (Cnidarians or coelenterates)	Cnidarians may be shaped like a cylinder, a bell, or an umbrella. Their bodies contain a jellylike material between two layers of cells. This phylum includes jellyfish, sea fans, sea anemones, and corals. About 9,000 species have been identified.	**Sea anemone**
Brachiopoda (Lamp shells)	Lamp shells have two hard shells that cover a soft body. They live in the oceans. Some attach themselves to rocks and other hard surfaces. Others burrow or lie loose in sand or mud. About 335 living species have been identified, and about 30,000 extinct species have been described.	**Lamp shell**
Acanthocephala (Spiny-headed worms)	These parasites live in many animals. They have a spiny tubelike structure called a *proboscis* on their head that attaches them to the wall of their hosts' intestines. Most measure about $\frac{3}{4}$ inch (2 centimeters) or less in length. About 600 species have been identified.	***Leptorynchoides thecatus***
Porifera (Sponges)	Sponges attach themselves to rocks and other objects at the bottom of oceans, lakes, or rivers. Many take the shape of such objects. Sponges have cells called *choanocytes* or *collar cells* that trap food particles within chambers in their bodies. About 5,000 species of sponges have been identified.	**Vase sponge**
Ctenophora (Comb jellies or sea walnuts)	These transparent animals live in oceans. They have eight bands of comblike organs on the side of their bodies. Most are pea-sized to thimble-sized. Comb jellies of a group called *Venus' girdle* can be over 3 feet (90 centimeters) long. About 90 species have been identified.	**Venus' girdle**
Nematoda (Roundworms or nematodes)	Many roundworms live in soil, water, or dead tissue. Some are parasites that are found in living plants and animals. Roundworms range from microscopic to about 3 feet (90 centimeters) long. The phylum includes filariae, hookworms, pinworms, and trichinae. About 12,000 species have been identified.	**Hookworm**
Platyhelminthes (Flatworms)	Many flatworms live as parasites in other animals. Flatworms have soft, thin, flattened bodies with three layers of cells. Most are less than 1 inch (2.5 centimeters) long. The largest flatworms, called *tapeworms,* are as long as 100 feet (30 meters). About 13,000 species have been identified.	**Planarian**
Nemertea or **Rhynchocoela** (Ribbon worms or proboscis worms)	Most ribbon worms live in the oceans. They have a slender, often flattened, body. They shoot out a proboscis from their head to capture prey. Most of these worms range from less than 1 inch (2.5 centimeters) to 8 inches (20 centimeters) long, but one species can reach a length of 100 feet (30 meters). About 900 species of ribbon worms have been identified.	**Bootlace worm**

Annelida
(Segmented worms)

The bodies of these worms consist of segments. Many of these worms have tentacles on their heads and a pair of leglike projections called *parapodia* on each body segment. Earthworms and leeches belong to this phylum. About 8,800 species have been identified.

Earthworm

Chaetognatha
(Arrow worms)

These worms have an arrow shape. They range from about $\frac{1}{4}$ to 6 inches (0.5 to 15 centimeters) long. They have movable hooks on their heads that they use to catch prey. They live in open seas, particularly in warm waters. About 100 species have been identified.

Arrow worm

Arthropoda
(Arthropods)

Arthropods have jointed legs, segmented bodies, and an outside shell called an *exoskeleton*. This phylum includes insects, such as ants, bees, beetles, and butterflies; crustaceans, such as crabs, lobsters, and shrimps; arachnids, such as mites, ticks, and spiders; centipedes; and millipedes. More than 1 million species have been identified.

Beetle

Echinodermata
(Echinoderms)

Echinoderms are spiny-skinned animals that have an internal bony skeleton. They are the only animals that have tiny tubelike structures called *tube feet*. This phylum includes brittle stars, sand dollars, sea urchins, sea cucumbers, and starfish. About 6,000 species have been identified.

Starfish

Mollusca
(Mollusks)

Mollusks make up the largest group of water animals, though some species live on land. Most mollusks have a hard shell that protects a soft body. The phylum includes clams, mussels, octopuses, oysters, snails, and squids. About 50,000 living species have been identified, and fossils of 100,000 extinct species have been found.

Snail

Chordata
(Chordates)

At some point in their life cycle, all chordates have a *notochord* (a rodlike, flexible cord that runs down the back of the body). A hollow nerve tube runs above the notochord. This phylum is the one to which human beings and many familiar animals belong. It includes amphibians, birds, mammals, and reptiles, as well as hagfishes, lampreys, and bony fishes. About 45,000 species have been identified.

Animal experimentation is the use of animals in biological, medical, and psychological studies. Human beings and many animals have similar organ systems and body processes. Experiments on animals help scientists increase knowledge about the way the human body works. Animal experimentation has played a part in many major medical advances, including the development of antibiotics, vaccines, and surgical techniques.

People have experimented with animals for hundreds of years, but the practice did not become widespread until the late 1800's. While animal experimentation has produced considerable benefits to people, it often results in the suffering and death of animals. Because of this, animal experimentation is a highly controversial issue. Animal experimentation that involves performing surgery on live animals is called *vivisection.* People opposed to this and other forms of animal experimentation are sometimes called *antivivisectionists.*

In the United States, scientists perform experiments on more than 20 million animals each year. However, some animal rights advocates estimate that as many as 100 million animals are used annually. Mice and rats account for about 90 percent of the animals used. Scientists also use birds, cats, dogs, guinea pigs, hamsters, monkeys, and rabbits. In addition, educators use animals to teach students about anatomy, physiology, biology, and surgery.

Reasons for experimentation. Medical researchers study animals to get a better understanding of body processes in humans and animals. They use many animals to study the causes and effects of illnesses, such as cancer and heart disease. In addition, they use animals to develop and test drugs, surgical techniques, and other medical therapies. Scientists use animals to test the safety of chemicals in food products and cosmetics. Psychologists observe the behavior of animals under a variety of conditions, such as hunger or stress, to learn how similar conditions might affect people.

The debate over animal experimentation. Some people call for an end to all animal experimentation. They believe either that such research is morally wrong or that benefits gained by animal research are trivial compared to the costs in animal suffering. Other people accept the need for such experimentation in medical and other scientific research but oppose animal testing of products that have no scientific value, such as cosmetics and perfumes. Many people argue for stricter laws to prevent mistreatment of laboratory animals. Critics of animal experimentation also believe that scientists should more thoroughly investigate other research methods. These methods include test-tube experiments on bacteria or on bits of human or animal tissue, and the use of computer models of living systems.

Most scientists, on the other hand, argue that without animal experimentation they could not continue to make significant progress in medicine and other sciences. They claim that the animal suffering caused by experimentation is minor. Scientists also point out that although other types of experiments are used whenever possible, such experiments are not always adequate. For example, testing a drug on isolated tissues or organs will not show how the drug affects the body as a whole.

Laws and regulations. In the United States, the Animal Welfare Act of 1966 requires scientists to provide adequate food and shelter for certain kinds of laboratory animals. Many private and government agencies that provide funds to research institutions regulate experimentation done by the institution. For example, the Public Health Service, a federal agency, requires each institution it funds to set up a committee to oversee the use and care of the animals. In 1992, in response to concerns about laboratory break-ins by animal rights advocates, a law was passed making it a federal offense to damage or disrupt animal research. Andrew N. Rowan

Animal husbandry. See Livestock.

Animal rights movement is a term that refers to organized efforts opposing the use of animals for research, food, and clothing. People who defend animal rights, called *animal rights activists,* point out that animals feel pain and have reasoning ability. They say that animals deserve greater moral consideration than human beings generally give them.

Most people agree that human beings have some obligations to animals, but they also believe that humans can use animals for certain purposes. For example, they argue that research on a few animals can save many human lives.

Some animal rights activists work to outlaw laboratory experiments on animals. Others teach that human beings do not need to eat animals for survival. Many activists protest the use of fur coats or leather products. They also oppose hunting and spectator sports in which animals may be treated inhumanely, such as bullfighting and dog racing.

The animal rights movement developed out of the animal protection movement. The movements have different opinions on how animals may be used. The animal protection movement tends to accept the need to raise animals for food and to use them in some research if they receive proper care. In contrast, the animal rights movement opposes any use of animals that results in injury or death to the animal. Public opinion polls show that most people agree with the less radical views of the animal protection movement.

The animal protection movement attracted many supporters at the end of the 1800's but declined during and after World War I (1914-1918). It began to reemerge after World War II (1939-1945), especially in the 1960's as interest in environmental issues increased. Animal rights became a central part of the animal protection movement during the 1970's. Since then, the movement has expanded at a dramatic rate worldwide. People for the Ethical Treatment of Animals and the Humane Society of the United States are leading animal protection organizations. Andrew N. Rowan

Animal worship is the practice of worshiping or honoring animals. Many societies worship animals because of a belief that everything in nature has a soul. This belief is called *animism.* A hunting society may worship an animal to gain its good will, to apologize for killing it, or to acquire the animal's qualities, such as speed or strength.

Many Indians of northern North America worshiped animals as part of a belief known as *totemism.* Each

group had its own sacred symbol called a *totem.* Most totems were animals. Many groups considered themselves descendants of their totem animal. Some people worship a god believed to have taken the form of an animal. For example, the ancient Egyptian god Thoth sometimes appeared as a baboon and sometimes as a wading bird called an ibis. Christopher McIntosh

See also Animism; Totem.

Animation is a visual technique that creates the illusion of motion, rather than recording motion through live action. The technique is used mainly for motion pictures. Animation can be created by illustrators, filmmakers, video makers, and computer specialists.

Animation is most popular in creating cartoon movies. Advertisers also employ animation to develop commercials for television. In addition, producers of instructional films may use animation to help explain a difficult idea or one that could not be shown in live action. Animation can also be combined with live action in a movie.

Traditionally, in making an animated film, a filmmaker photographs a series of drawings or objects one by one. Each drawing or shape of an object takes up one frame of the film. The position of a character or scene changes slightly from frame to frame. When the film is shown through a projector, the pictures appear to move.

Animation can exist with little technology. One simple animation device is the *flip book,* a group of sketches in sequence placed one on top of the other. When a viewer flips the pages rapidly, the images appear to move.

Preliminary steps in animation

Today, the use of computers has brought significant changes to animation production. But several processes remain the same in both traditional and new methods.

The first step in making any animated film is creating a story. After a story has been established, an artist and writer prepare a *storyboard,* which serves as the film's script. The storyboard resembles a giant comic strip. It consists of rough sketches that portray the action of the story, with the dialogue accompanying each sketch.

After the director and other key personnel approve the storyboard, performers make a recording of the dialogue and any music. The recorded sound must be *synchronized* (made to occur at the same time and the same speed) with the action. The composer and actors carefully follow the storyboard to make sure the music and dialogue match each sequence of the action.

Animators work from a guide called an *exposure sheet* that indicates the number of frames needed to express each movement and each word of the recorded dialogue. Animators synchronize animation to sound using a guide called a *bar sheet* or working from *digitized sound files* on a computer. *Digitizing* is the process of converting a sound or image into a format that a computer can read. After completing these preliminary steps, the animation process continues, using any of several techniques.

The contributors of this article, John Canemaker and Peter Weishar, are animators who have both written widely on the art of animation. Canemaker is head of the animation program at New York University's Tisch School of the Arts. Weishar is a Professor of Film and Television at New York University.

Animated films have been popular since the earliest days of motion pictures. Many short animated films feature humanlike animal cartoon characters, such as Bugs Bunny and Daffy Duck.

Cel animation

Cel animation has traditionally been the most common technique used to make animated cartoons. The technique is named for the clear sheets of celluloid acetate on which animators trace and paint the images and backgrounds. Tens of thousands of separate cels in sequence are required for a feature-length animation movie, such as *Snow White and the Seven Dwarfs* (1937) or *Pinocchio* (1940), and a lesser number for many television cartoons.

Artists called *layout artists* work with the director to determine what settings will be drawn, how each character will act and look, and how the action can best be broken down into scenes. After these decisions have been made, the layout artists prepare drawings to guide two other groups of artists—*background artists* and *animators.* The background artists draw all the backgrounds for the film—that is, everything that will appear on the screen except the characters.

The animators make separate drawings of the characters. Working from the exposure sheet, the animators must create the exact number of drawings required by the action and dialogue. In one episode, for example, a character may answer the telephone by saying "Hello." The exposure sheet shows that the word "Hello" requires eight frames. The animators thus must make eight drawings in which the character's mouth moves in sequence to form the word. They must also include all the character's body movements.

After the animators complete their drawings, another group of artists trace them onto the cels. A painting department applies the proper colors to the reverse side of the cels. The completed cels are then sent to the camera department, where camera operators photograph the cels frame by frame over the proper background. The exposure sheets tell the camera operator which cels and backgrounds are needed for each frame. After the photography is completed, the sound track is added. Prints of the film are made, and the movie is released.

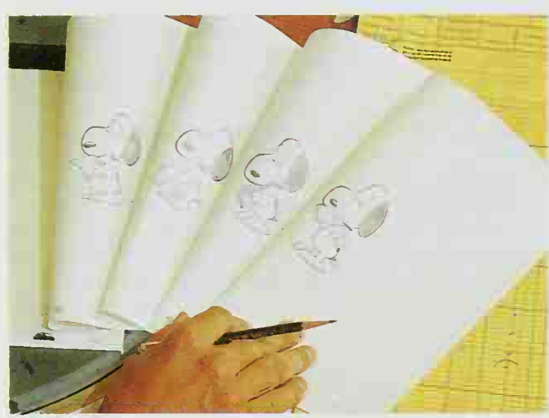
Computer animation

Skilled animators continue to make many drawings by hand. Since the mid-1980's, however, computer assistance combined with hand-drawn animation has become standard in many movie studios. The combined method created such feature-length animated films as *The Lion King* (1994) and *The Prince of Egypt* (1998).

Today, computer techniques have replaced cels, as well as the tedious tasks of hand-inking, painting, and photographing them. Animators scan drawings into a computer, which cleans up the images and colors them. Hand-painted backgrounds are also scanned into a computer and combined with the characters. The computer eliminates laborious hand coloring and offers a vast choice of colors. Computerized backgrounds can also have numerous levels, creating an illusion of depth. Computer experts match the final animation to the sound track and then transfer the animation from the computer to film or videotape.

One increasingly important type of animation is *computer-generated imagery* (CGI), in which the computer creates the characters and backgrounds and animates them without actually photographing either cels or figures. Films made entirely with CGI include *Toy Story* (1995), *Antz* (1998), and *A Bug's Life* (1998).

Most CGI-animated characters start with a sketch or small sculpture called a *maquette* that is used for reference. The artist then creates a computer image called a *wireframe model*. The wireframe model serves as a framework for a shell or skin that gives the computer image a solid, three-dimensional appearance.



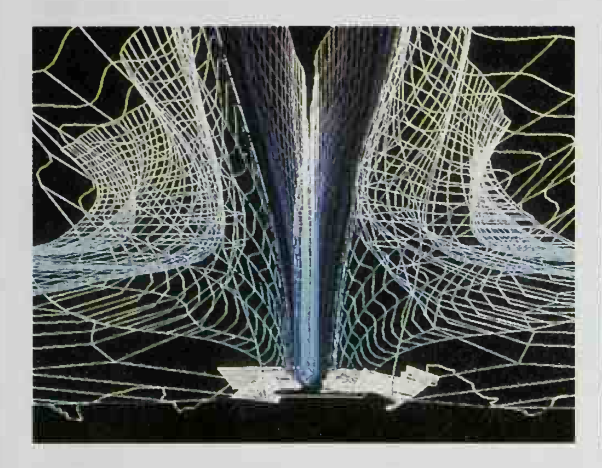
To move the character, a computer animator changes the positions of the wireframe model in a number of key frames. The computer then supplies the frames between the key frames, moving the model from one of the animator's positions to the next.

After creating the three-dimensional model, the artist adds color, texture, and shading in a process known as *texture mapping*. Texture mapping makes the surfaces of the characters and scenery look real. A texture map can be created by a computer program or scanned from an actual photograph.

The final step is called *rendering*. During rendering, the computer calculates the effect of light, color, and texture on the model's surface. For a film or video, the

Cel animation Cel animation is the technique of creating cartoons on clear sheets called *cels*. In the first picture, an animator draws the characters, creating drawings for each movement a character makes. After artists trace the drawings onto cels, other artists paint the cels with the colors needed for each character (second picture). The completed cels are placed over backgrounds drawn by background artists (third picture). A special camera is used to photograph the cels and backgrounds, one frame at a time (fourth picture).

WORLD BOOK photos by John R. Hamilton, Globe Photos



Computer animation

Computer animation is now the leading animation technique. This photo sequence shows some of the steps needed to create a single frame. The first picture shows a computer image called a *wireframe model.* After creating the three-dimensional model, the artist in the next picture has added color, texture, and shading in a process known as *texture mapping.* The third picture shows the rough animation stage of the scene. The fourth picture reproduces a completed frame as it will appear on the motion-picture screen.

computer will produce a two-dimensional digital picture of the characters for each frame of the animation. The computer artist usually adjusts many visual effects, such as camera focus and transparency, during the rendering phase. Some computer programs enable the artist to "paint" color directly on the three-dimensional model. A single animation may take hours or even weeks to render. For example, six powerful computers took 24 hours to render a single second of some scenes from *A Bug's Life.*

Computer-generated characters can be combined with live action in a process known as *compositing.* The science fiction film *Jurassic Park* (1993) popularized this technique when it combined realistic, computer-generated dinosaurs with actual actors and sets. Compositing can also be used to combine real actors with computer-generated sets and special effects.

Other kinds of animation

There are several kinds of animation in general use besides cel and computer-generated animation. They include (1) puppet animation, (2) clay animation, (3) pixilation, (4) pin screen animation, and (5) drawing on film.

Puppet animation uses three-dimensional figures or objects. This type of animation is frequently used in making short animated films, but it has also been the technique of such feature films as *The Nightmare Before Christmas* (1993) and *James and the Giant Peach* (1996). Puppet animation also appears at times in live action features, such as *Star Wars* (1977) and *E.T.: The Extra-Terrestrial* (1982).

Two types of photography make puppet animation possible. They are called *stop motion* and *go-motion.* Stop motion uses a camera that is stopped after a single frame is photographed. Each time the camera stops, animators make slight, sequential adjustments in the positions of the figures or objects. When the frames are projected in rapid succession, the models appear to move.

Go-motion is a refinement of stop motion. Special computers and other equipment control the movement of both the models and the camera photographing them. This process slightly blurs the movements of the

Puppet animation also appears at times in live action features, such as *Star Wars* (1977) and *E.T.: The Extra-Terrestrial* (1982).

Two types of photography make puppet animation possible. They are called *stop motion* and *go-motion.* Stop motion uses a camera that is stopped after a single frame is photographed. Each time the camera stops, animators make slight, sequential adjustments in the positions of the figures or objects. When the frames are projected in rapid succession, the models appear to move.

Go-motion is a refinement of stop motion. Special computers and other equipment control the movement of both the models and the camera photographing them. This process slightly blurs the movements of the

Photofest

Puppet animation was used in the famous motion-picture thriller *King Kong* (1933). Animators used *stop motion*, creating a small model of a gorilla that appeared as a giant on the screen.

models, making them look more natural on film. For example, the children on bicycles flying across a moonlit sky in *E.T.* were animated by go-motion.

Clay animation is a type of puppet animation that uses figures or objects made of clay. This technique is often used for television commercials and short animated films.

Pixilation is a way of animating live action. When the camera is stopped, the actors slightly alter their positions. Pixilation makes people look cartoonlike on film.

Pin screen animation is a seldom-used technique that employs a large white screen with about 1 million pinholes. Animators place headless pins into the holes and light the screen from the side. Images are created by shadows from the light falling on the pins. Animators move the pins to change the images. After each change, they photograph the screen to produce a series of frames for animation.

Drawing on film is an inexpensive technique that requires little equipment. The animator draws or paints the sequence of images directly on the film stock, instead of photographing them with a camera.

History

Early animation. The first examples of animation were motion toys developed in the 1800's. One of the earliest devices was the *phenakistoscope*, invented by the Belgian scientist Joseph Antoine Plateau in 1832. It was a notched wheel attached to a handle. One side of the wheel had a series of drawings. The viewer held the wheel up to a mirror, with the drawings facing the mirror. When the viewer spun the wheel and looked though the notches on the blank side of the wheel, the images appeared to move. Such devices contributed to the invention of motion pictures.

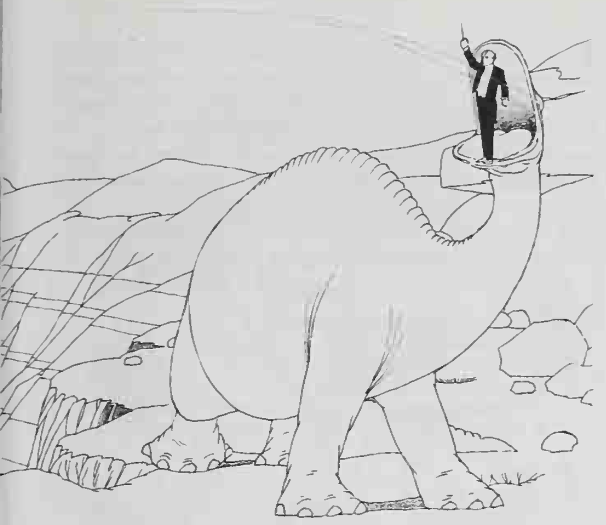
Arthur Melbourne-Cooper of England was one of the first people to make motion pictures using animation. In 1899, Melbourne-Cooper moved matchsticks in different sequences and photographed them frame by frame to produce an advertisement called *Matches: An Appeal.*

J. Stuart Blackton, a British-born American newspaper cartoonist, was the first person to film drawings frame by frame. In 1906, Blackton made *Humorous Phases of Funny Faces* by filming a series of faces drawn on a blackboard.

Émile Cohl of France was another important early animator. Cohl made about 250 short animated films from 1908 to 1921, beginning with *Fantasmagorie.*

Pioneers of American animation. In New York City, Winsor McCay exhibited his first animated film, *Little Nemo*, in 1911. McCay's most famous animated short film was *Gertie* (1914). McCay produced high-quality films that featured cartoon characters with graceful movements and distinct personality traits. He established the techniques and visual approaches that set the standard for character animation. McCay's work became influential for its fluid motion, high-quality draftsmanship, and feeling of weight.

In 1914, animator John Randolph Bray began streamlining the production processes involved in animation. Under Bray, studios hired large staffs and operated like assembly lines, making cartoons cheaper and faster to produce. Bray collaborated with animator Earl Hurd, who had patented the cel technique. Together they revolutionized the animation process. Before cels were used, animators had to completely redraw both the characters and the background for each frame in a scene. With cels, however, animators draw the background only once, saving work.



American movie studios began producing several series of animated films featuring regular cartoon characters about 1915. Otto Messmer created the *Felix the Cat* series, which was produced by former newspaper cartoonist Pat Sullivan. Felix was the first internationally popular animated character. Messmer directed more than 150 short Felix films during the 1920's.

Max Fleischer, a former newspaper cartoonist, and his brother Dave produced animated series featuring Koko the Clown, Betty Boop, and Popeye the Sailor. Other well-known cartoon characters of the early 1900's included Krazy Kat and Mutt and Jeff. Some of the characters first appeared in newspaper comic strips.

Animation in Europe. While animators in the United States concentrated on developing cartoon characters, animators in Europe experimented with creative techniques. From 1910 through the 1920's, for example, the Polish-born artist Ladislas Starevitch (whose name is also spelled Wladyslaw Starewicz) used puppet animation. Germany's Lotte Reiniger produced short animated films with black silhouettes and created the first feature-length animated film, *Adventures of Prince Achmed* (1926).

Some European artists experimented with abstract animation. The German artists Walter Ruttmann and Oskar Fischinger created animated short films with abstract geometric shapes. Two book illustrators in France—Russian-born Alexandre Alexeieff and American-born Claire Parker—developed pin screen animation during the early 1930's.

Walt Disney became the most famous producer of animated films. He created such popular cartoon characters as Mickey Mouse, Donald Duck, Goofy, and Pluto. Disney produced *Steamboat Willie*, starring Mickey Mouse, in 1928. It was the first animated cartoon with a

John Canemaker Collection

An early animated film by Winsor McCay in 1914 starred Gertie the dinosaur. McCay pioneered in creating cartoon characters with flexible movements and distinct personality traits.

synchronized sound track that integrated music, voices, and sound effects. From 1928 to 1939, Disney perfected the character animation film, mainly through his popular cartoon series called *Silly Symphonies.*

In 1937, Disney issued *Snow White and the Seven Dwarfs,* his first full-length animated film. It became one of the most popular films in movie history. Disney later produced such animated feature-length films as *Pinocchio* (1940), *Fantasia* (1940), *Dumbo* (1941), *Bambi* (1942), and *Lady and the Tramp* (1955). Disney's influence on animated storytelling, design, and artistic theory continues to be felt throughout the animation industry.

Animation in the mid-1900's. Along with Disney, several other major film studios dominated the animation industry from the 1930's to the early 1950's. At Metro-Goldwyn-Mayer (MGM), William Hanna and Joseph Barbera made short animated features starring Tom and Jerry, a cat and mouse team. Walter Lantz of Universal Studios produced animated shorts featuring Oswald the Rabbit and later Woody Woodpecker.

At Warner Brothers, Tex Avery, Chuck Jones, Bob Clampett, and Friz Freleng directed animated shorts starring Bugs Bunny, Daffy Duck, Elmer Fudd, and Porky Pig. Also during this period, the Scottish-born animator Norman McLaren made acclaimed animated films for the National Film Board of Canada. McLaren became best known for his technique of drawing directly on film. His animated movies include *Begone Dull Care* (1949) and *Neighbors* (1952), a pixilation film.

In the early 1940's, a group of animation artists left the Disney studio. They established United Productions of America (UPA) in 1945. This group broke away from Disney's emphasis on realism, stressing instead a bold, flat, modernist style. Famous UPA cartoon characters included Gerald McBoing Boing and Mr. Magoo. UPA also popularized a technique called *limited animation* that differed from the full-figure animation done by Disney. In limited animation, only certain simple movements of a character are animated, allowing portions of the figure to be reused. The UPA style proved less expensive than full-figure animation and influenced many other studios. The low cost of limited animation made it popular for children's television cartoons, such as "The Flintstones" and "Yogi Bear" by Hanna-Barbera Productions. In 1960, "The Flintstones" became the first animated series to appear on prime-time television.

Some animators left UPA to form their own production companies. Among the most talented was John Hubley. He and his wife, Faith, created films that expanded the content and style of character animation. Their best-known animated films include *Moonbird* (1959), *Windy Day* (1968), and *The Doonesbury Special* (1977).

Computer scientists and artists began to experiment with computer visualization in the 1960's. In the early 1970's, a few academic institutions, such as the University of Utah, animated simple shapes with computers.

Photofest

Animation and live action were combined in the Hollywood musical film *Anchors Aweigh* (1945). Gene Kelly danced with Jerry the mouse of the popular cartoon team of Tom and Jerry.

© Walt Disney Pictures from Shooting Star

Toy Story, released in 1995, was the first feature-length animated film that was entirely computer generated. The movie follows the adventures of toys living in a boy's bedroom.

The animation revival. Production of feature-length animated cartoons declined from the mid-1950's through the 1960's, partly because of the rising popularity of television. However, a revival of feature-length animated cartoons began during the 1970's. The American director Steven Spielberg released his first animated cartoon feature, *An American Tail,* in 1986. Disney's *Tron* (1982) and Spielberg's *Jurassic Park* (1993) became milestones in their use of computer-generated characters as an essential part of the film. The Disney and Spielberg studios jointly produced *Who Framed Roger Rabbit* (1988), which combined live action and animation. Disney followed with several innovative and popular features, including *The Little Mermaid* (1989), *Beauty and the Beast* (1991), *Aladdin* (1992), and *The Lion King* (1994).

In the late 1990's, the animation department of a new studio, DreamWorks SKG, began releasing animated features, notably *Antz* and *The Prince of Egypt.* Like Disney, DreamWorks employed both traditional and computer-generated methods. DreamWorks also issued the popular *Chicken Run* (2000) in the clay animation style. Also in the late 1990's, animated series on television proved popular with older viewers. Such series as "The Simpsons" and "King of the Hill" achieved high audience ratings.

Animation today. Today, animators throughout the world create films of all lengths. Thousands of artists work in animation houses in such countries as South Korea and Japan. They turn out hundreds of feature-length films as well as animated cartoons and commercials for television. Many Canadian, U.S., and Russian animators operate smaller studios.

Computer animation has become a thriving industry. Computer-generated images (CGI) now play a major role in many Hollywood films. The cost of the technology has dropped, helping to make CGI common in TV programs and commercials. CGI and other new technologies have blurred the boundaries between live action and animation. Digital effects combined with animation have opened up limitless possibilities for filmmakers because almost anything that can be imagined can be realized on the screen. John Canemaker and Peter Weishar

Animism, *AN uh mihz uhm,* is a term used to describe certain religious beliefs based upon the concept of a soul that departs the body after death. The British anthropologist Edward Burnett Tylor introduced the term in 1871, from the Latin word *animae* meaning *souls* or *spirits.* He argued that early people first developed the idea of the soul from dreams about the dead.

Scholars today have rejected Tylor's theory. However, many believe that animism is the basis of later religions, including Judaism, Christianity, and Islam. Elliot Fratkin

See also **Mythology** (Tylor's theory); **Religion** (Tylor's theory).

Anise, *AN ihs,* is an annual herb related to caraway and dill. It is grown mainly for its seeds, which have a spicy taste and are used to give candy a licorice flavor. They are also used to flavor pastries, cookies, and certain kinds of cheese. The oil extracted from the seeds is used to make absinthe, an alcoholic beverage. The oil is also used in medicines, especially those for treating children's stomach troubles. Many cooks use anise leaves as a garnish or for seasoning soups and sauces.

Anise grows wild in the Mediterranean region. It needs warm, dry summers to grow well. Egypt, Germany, Italy, Mexico, Spain, and Turkey are important anise-producing countries. Albert Liptay

WORLD BOOK illustration by Carol A. Brozman

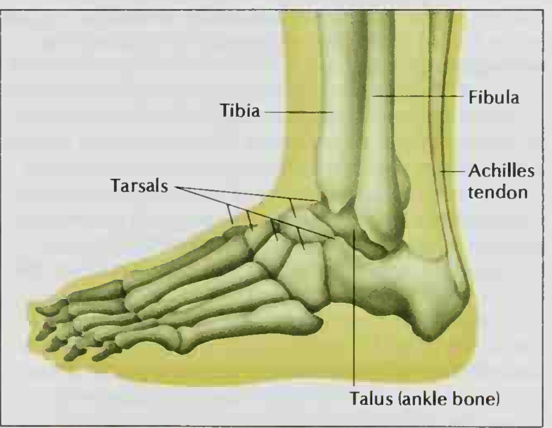
The anise plant produces seeds that give food a spicy licorice flavor. A seed pod grows out of the center of each flower.

Scientific classification. Anise is in the parsley family, Apiaceae or Umbelliferae. Its scientific name is *Pimpinella anisum.*

Ankara, *ANG kuh ruh* (pop. 2,559,500), is the capital of Turkey. It ranks second to Istanbul as the country's largest city. Ankara lies in a hilly area in west-central Turkey. For location, see **Turkey** (political map).

Ankara has an old section and a modern section. The old section is on a hill and consists of a fortress that is hundreds of years old. After Ankara became Turkey's capital in 1923, a modern section began to grow at the base of the hill. It has merged with the old section. The Museum of Anatolian Civilizations in Ankara has an outstanding collection of Hittite art. Many Turks and other travelers come to the city to visit the tomb of Kemal Atatürk, founder of the Republic of Turkey. Ankara is the home of the University of Ankara, the Middle East Technical University, Bilkent University, and Hacettepe University. The National Library of Turkey is also in the city.

The Turkish government employs more of Ankara's people than does any other kind of business. The city serves as a market for the grain, Angora wool and mohair, and other farm products of the area. Ankara's industries process food and produce building materials, farm equipment, and various kinds of machinery.



People probably lived in what is now the Ankara area during the Stone Age, which began about 2 ½ million years ago. By about 700 B.C., Ankara had become an important town of Phrygia (now central Turkey). Alexander the Great of Macedonia conquered Ankara in the 330's B.C. The Romans took over the town in 25 B.C. In the Middle Ages (about the A.D. 400's through the 1400's), several groups gained and lost control of Ankara.

By 1360, the Ottomans had captured the city and made it part of the Ottoman Empire. The empire was defeated in World War I (1914-1918). Kemal Atatürk established a nationalist government in Ankara in 1920. Ankara became the capital of the Republic of Turkey in 1923. Since 1922, its population has grown from about 15,000 to more than 2 ½ million. F. Muge Gocek

See also **Turkey** (picture).

Ankle is the joint where the leg and the foot meet. The ankle joint enables the foot to move up and down.

Each leg has two bony bumps—one on each side—that we commonly call the *ankles.* These bumps are formed by the ends of the lower leg bones, the *tibia* and the *fibula.* Below the leg bones are seven *tarsal bones,* which extend about halfway down the foot. The top of the *talus,* the highest tarsal bone, fits between the ends of the tibia and the fibula and moves between them like a hinge. The *Achilles tendon* links the heel bone—the largest tarsal bone—to the calf muscles and helps move the ankle joint.

WORLD BOOK illustration by Leonard Morgan

The ankle joint allows movement of the foot. The talus, one of seven tarsal bones, fits between the lower ends of the tibia and fibula and moves between them like a hinge.

Three small joints among the tarsal bones enable the foot to move sideways. Many strong, cordlike tissues called *ligaments* connect the tarsal bones to the leg bones, to the bones lower in the foot, and to one another. If one of these ligaments is torn, a sprained ankle results. John F. Waller

See also **Achilles tendon; Ligament; Sprain.**

Ankylosaurus, *ANG kuh luh SAWR uhs,* was a large, armored dinosaur that lived between 68 million years and 65 million years ago in what is now western North America. The name *Ankylosaurus* means *fused lizard* and describes the dinosaur's armor, which consisted of bony pieces that had *fused,* or grown together. This heavy armor protected all the exposed parts of the body, including the head, back, and tail.

Ankylosaurus was one of the largest of the armored dinosaurs. It was about 30 feet (9 meters) long and weighed about 4 to 5 tons (3.6 to 4.5 metric tons). It was a plant-eater with small teeth. The dinosaur's triangular skull was 2 ½ feet (76 centimeters) long and equally wide. A spike stuck out from each cheek, and two more stuck out from the back of the head. Short, thick legs supported the weight of the dinosaur's low, broad body. The tail

ended in a big, heavy ball of bone.

When attacked, *Ankylosaurus* may have crouched down and pressed itself to the ground. In this position, the attacker could only bite or claw at the thick, hard armor. *Ankylosaurus* also may have defended itself by swinging its tail and hitting an attacker with the bony club at the end. Peter Dodson

See also **Dinosaur** (picture: When dinosaurs lived).

Ankylosis, *ANG kuh LOH sihs,* means a stiffening or a fusion of a joint, preventing motion. Ankylosis may result from infection or severe injury to a joint. It also may be accomplished surgically to eliminate pain, as in an arthritic joint, or to stabilize a loose joint, as in poliomyelitis. Ankylosis of the knee, hip, shoulder, and most other major limb joints considerably diminishes the limb's function. But surgical ankylosis to relieve pain or improve stability may increase limb function, particularly when the fusion corrects a deformity. William J. Kane

Ann Arbor, Michigan (pop. 114,024; met. area pop. 578,736), is the home of the University of Michigan. It lies on the Huron River, west of Detroit. For location, see **Michigan** (political map).

Several county and civic buildings and part of the University of Michigan are in downtown Ann Arbor. Another campus of the university is in the northeastern part of the city. Many computer and other electronics firms in Ann Arbor conduct research and manufacture electronic equipment. The city is also a printing and publishing center. Concordia University is in Ann Arbor. Detroit Metropolitan Airport, railroads, and bus lines serve the city.

Two pioneers from Virginia and New York founded Ann Arbor in 1823. They named it *Ann* after the first name of both their wives, and *arbor* for a grove of beautiful oak trees there. Ann Arbor was incorporated as a city in 1851. It is the seat of Washtenaw County and has a council-manager form of government. Peter Gavrilovich

Annan, *AN uhn,* **Kofi Atta,** *KOH fee AT uh* (1938-), is a diplomat from Ghana who in 1997 became the seventh secretary-general of the United Nations (UN). He replaced Boutros Boutros-Ghali of Egypt, who held the office from 1992 through 1996. Annan became the first secretary-general from Africa south of the Sahara.

Annan has received praise for his support of human rights and for his campaigns against AIDS and international terrorism. He and the United Nations won the 2001 Nobel Peace Prize for their efforts in building peace and security throughout the world.

Annan was born in Kumasi, Ghana. He studied in the United States, earning a bachelor's degree in economics from Macalester College in 1961. He also received a master's degree in management from Massachusetts Institute of Technology in 1972.

Annan began his career with the UN as an administrative and budget officer at the World Health Organization (WHO) in 1962. From 1993 to 1996, he served as under-secretary-general for peacekeeping operations. He also carried out difficult diplomatic assignments. In 1991, Annan negotiated the release of UN staff members held in Iraq during the Persian Gulf War. Mark W. DeLancey

See also **United Nations** (picture).

Annapolis, *uh NAP uh lihs* (pop. 35,838), is the capital of Maryland and the home of the United States Naval Academy. It lies along the Severn River on the western shore of Chesapeake Bay (see **Maryland** [political map]).

The layout of the city features two central circles, with narrow streets branching off in all directions. Colonial buildings give Annapolis a historic charm. They include Paca House, built in 1763 by Governor William Paca; and the red brick State House, built in 1772. The State House is the oldest state capitol still actively used by a legislature. The Continental Congress met in the State House when Annapolis was the United States capital, from Nov. 26, 1783, to June 3, 1784. It was in this building that George Washington resigned as commander of the Continental Army on Dec. 23, 1783. St. John's College was founded as an academy in Annapolis in 1696.

The city is a yachting center. Its economy is based heavily on tourism and government activities. Puritans founded Annapolis in 1649. Annapolis was named for Queen Anne of Britain, who gave the city its charter in 1708. It has a mayor-council government. The city is the seat of Anne Arundel County. Thomas L. Marquardt

See also **Maryland** (picture: State Capitol); **United States Naval Academy.**

Annapolis Convention, *uh NAP uh lihs,* was a meeting held in Annapolis, Maryland, in 1786 to discuss changes in the Articles of Confederation, which had served as the basic law of the United States since 1781. The proposed changes referred especially to commercial issues. Virginia invited all the states to the convention, but only New York, New Jersey, Pennsylvania, Delaware, and Virginia attended. Many political leaders, including Alexander Hamilton and James Madison, urged that all the states send delegates to a second convention. Meeting in Philadelphia in 1787, this second convention abandoned the Articles and wrote the Constitution of the United States. Donna J. Spindel

See also **Constitution of the United States.**

Annapolis Royal, *uh NAP uh lihs,* Nova Scotia (pop. 550), is one of the oldest communities in North America. It lies along the Annapolis Basin, an inlet of the Bay of Fundy (see **Nova Scotia** [political map]). French colonists founded the settlement of Port Royal near what is now Annapolis Royal in 1605. English raiders captured and burned the colony in 1613. In the 1630's, the French reestablished the settlement at the present site of Annapolis Royal. Port Royal became a military outpost and often changed hands during continual fighting between French and English forces in the area.

In 1710, the British captured the settlement and renamed it Annapolis Royal. The town served as the capital of Nova Scotia until Halifax became the capital in 1749. Annapolis Royal prospered as a shipping center in the 1800's. Today, it is a popular tourist resort. Attractions include the nearby Habitation, a replica of the original French settlement founded in 1605. D. A. Sutherland

Annapurna, *AN uh PUR nuh,* a small range of mountains within the Himalaya, includes some of the highest peaks in the world. It stands in north-central Nepal. Its highest peak, known as Annapurna I, rises 26,504 feet (8,078 meters). The Nepalese call this snowy peak the *Goddess of the Harvests* because they believe it watches over the farms below. In 1950, a French expedition led by Maurice Herzog climbed it. Until the conquest of Mount Everest in 1953, Annapurna was the highest mountain people had climbed. See also **Mountain** (diagram: Major mountains). James A. Hafner

Anne (1665-1714) was the first queen of Britain, which was formed when the Kingdom of Scotland united with the Kingdom of England and Wales in 1707. She was also queen of Ireland. Anne was the last monarch of the royal family called the House of Stuart. She became pregnant at least 17 times and had 5 children, but none survived her. She was succeeded by her distant cousin George, Elector of Hanover.

Anne was born at Twickenham, near London. She was the second daughter of King James II and married Prince George of Denmark in 1683. She became queen in 1702, after the death of her brother-in-law William III, who left no heirs. During most of her reign, John Churchill, Duke of Marlborough, wielded much power. He was captain-general in the War of the Spanish Succession (1701-1714). His wife, Sarah, dominated Anne for years. Their interference made the court a scene of political intrigue.

Detail of portrait by M. Dahl (1699). National Portrait Gallery, London

Queen Anne

Although Anne's health was never good, she took an active part in public affairs. She often attended debates in the House of Lords and was particularly concerned with religious legislation. Anne's reign is often said to mark the start of the *Augustan Age,* because the leaders of the times tried to reproduce in England the political stability and classical art of Rome under the Emperor Augustus. These leaders included the writers Alexander Pope, Jonathan Swift, Joseph Addison, and Richard Steele. James J. Sack

See also Marlborough, Duke of; Furniture (The Queen Anne style); Stuart, House of.

Anne, Saint, is traditionally regarded as the wife of Joachim and mother of the Virgin Mary. Stories about her life are found only in the apocryphal books of the New Testament. According to these stories, an angel appeared to her and announced that her child would be blessed by the whole world. Saint Anne has many shrines built to her. One of the best known is that of Ste.-Anne-de-Beaupré near Quebec City, Canada. See also Sainte-Anne-de-Beaupré. J. H. Charlesworth

Anne of Austria (1601-1666) was the wife of King Louis XIII of France and the mother of King Louis XIV. After her husband's death in 1643, she ruled France as queen *regent* (temporary ruler) for her young son. Anne governed during the difficult end of the Thirty Years' War (1618-1648) and the civil disruptions in France known as the *Fronde* (1648-1653). In 1651, in response to criticism of Anne's regency by rebellious nobles of the Fronde, 13-year-old Louis XIV was formally declared old enough to rule. But Anne continued to play a dominant role in government policy during his teen-age years and beyond. Anne's chief minister and principal adviser throughout this time was Jules Cardinal Mazarin.

Anne was born in Valladolid, Spain. Her parents were King Philip III of Spain and Margaret of Austria.

Donald A. Bailey

See also Louis XIV; Mazarin, Jules Cardinal.

Annealing, *uh NEEL ihng,* is a process of heating metals, glass, or other materials and then cooling them. The cooling is usually done slowly. Annealing produces various changes in the composition and properties of metals. Most of these changes are desirable. For example, it makes metals softer so that they can be machined more easily. It also can reduce internal pressures called *stresses* from metals. Stresses may result during the manufacture of metal products or during their use.

The purpose of annealing glass is always to remove internal stresses that might later cause sudden cracking or breakage. Stresses are likely to be present because of unequal temperature distribution in the glass article while it is being cooled from its molten state. Glass articles are annealed by placing them on a metal belt that travels slowly through a long, heated enclosure called a *lehr.* Thin articles can be annealed in 30 minutes or less. But it took more than a year to anneal the huge 200-inch (508-centimeter) telescope lens for the Palomar Observatory in California. I. Melvin Bernstein

See also Tempering.

Annenberg Foundation is a charitable organization that exists to advance the public well-being through improved communication. The organization achieves its goal by encouraging the development of more effective ways to share ideas and knowledge. The foundation grants money primarily to programs designed to improve elementary and secondary education. In the middle and late 1990's, for example, the foundation donated $500 million to public school reform efforts.

The Annenberg Foundation was established in 1989 by Walter H. Annenberg, former president and chairman of Triangle Publications, Inc., and United States ambassador to the United Kingdom from 1968 to 1974. The foundation offices are in St. Davids, Pennsylvania, near Philadelphia. Critically reviewed by the Annenberg Foundation

Annexation, *AN uhk SAY shuhn,* is a method that governments use to acquire and establish sovereignty over new territory. Some authorities consider conquest or the use of force as the only means of annexation. However, other authorities believe that cession, purchase, and discovery and occupation are other means. Many cities and other municipalities in the United States have annexed nearby areas by referendum and other legal means.

An annexed territory becomes an integral part of the annexing country. Protectorates, leased territories, and areas under military occupation are not annexed lands, because they do not become an integral part of the country controlling them. The citizens of an annexed territory must change their allegiance and become citizens of the annexing country. Laws of the annexed territory that are not in conflict with those of the annexing country may be retained, though special arrangements for limited self-government may also be made. The annexing country also inherits such treaty obligations as the territory may have had prior to its annexation.

Annexations have been the cause or result of many wars. For example, Italy annexed Ethiopia in 1936, and Germany annexed Austria in 1938. During and after World War II, the Soviet Union annexed territories in eastern Europe and the Far East covering about 270,000 square miles (699,000 square kilometers). In 1898, following the Spanish-American War, Spain ceded Puerto

Rico, the Philippines, and Guam to the United States. Many annexations have been made peacefully. The United States annexed Texas in 1845 and Hawaii in 1898 following consent by governing authorities. France ceded the Louisiana Territory to the United States in 1803 for about $15 million. Robert J. Pranger

Anniversary, Wedding. See Wedding anniversary.

Anno Domini. See A.D.

Annual is a plant that grows, blossoms, produces seed, and dies within one growing season. Plants called *biennials* require two growing seasons to complete their life cycles. Other plants, called *perennials,* can live for many years. Many garden vegetables and flowers are annuals. Such plants, which include beans, peas, petunias, squash, and zinnias, must be raised from seed each year. Joseph E. Armstrong

See also **Biennial; Flower** (Garden annuals); **Gardening; Perennial.**

Annuity, *uh NOO uh tee,* is a sum of money paid out at regular times, usually monthly or yearly. The word comes from the Latin word *annus,* meaning *year.* Insurance policies, wills, and other documents provide for annuities. People may leave money to an heir in the form of an annuity. The inheritance will then be paid in installments instead of in a lump sum. Usually the term *annuity* refers to a type of insurance. Individuals pay the insurance company a certain amount of money. They receive in return an income that begins at a certain time and continues for a certain period. For instance, payments may begin when a person reaches 60 and continue until the person's death. Pension plans also provide for annuities. The most common use of annuities is to provide regular payments during a person's retirement years. See also **Insurance** (Annuities); **Pension; Social security.**

Dan R. Anderson

Annulment is the declaration that a marriage never really existed, or was void from the beginning. Most states of the United States, as well as many religious groups, have strict laws saying that first cousins may not marry each other. If two persons are found to be within the forbidden degree of *consanguinity* (blood relationship) their marriage can be annulled.

Annulments are sometimes granted for other reasons, such as fraud or undue force exercised against one of the parties. A marriage can also be annulled if either party is under age, or if both parties declare that they considered the ceremony a joke at the time it was performed. An annulment differs from a divorce, which has the effect of dissolving a valid marriage for some cause arising after the ceremony. Except in special cases, the Roman Catholic Church does not recognize divorce, but it does recognize annulment.

Annunciation, *uh NUHN see AY shuhn,* is the announcement, according to Luke 1: 26-38, which the angel Gabriel made to Mary. He told her that she was to be the mother of Jesus, who was to be called "the Christ."

The Annunciation should not be confused with the Immaculate Conception of Mary. In Roman Catholic belief, the Immaculate Conception means that Mary, at the instant of her existence in her mother's womb, was free from original sin.

Beginning in medieval times, the words of the angel at the Annunciation, "Hail, full of grace, the Lord is with thee," gradually became the opening words of the "Hail Mary" prayer, though that prayer did not receive its full form until the 1500's. Another devotion honoring the Annunciation developed into the present "Angelus," and began in the early 1300's. Three Hail Marys are recited at morning, noon, and evening, when church bells are also rung to commemorate the incarnation of Jesus. The Annunciation has been the subject of paintings by great artists, including Fra Angelico, Andrea del Sarto, and Jan van Eyck. Mary is usually shown holding a book or some needlework, and Gabriel carries an olive branch or a flower. J. H. Charlesworth

Anodizing, *AN uh DYZ ihng,* is a type of electrolysis used to place a protective oxide coating on metal. The metal acts as the *anode* (positive pole) of an electrolytic cell. Negatively charged oxide ions pass through a solution called an *electrolyte,* and oxidize the surface of the metal. Aluminum can be anodized in a sulfuric acid solution. Magnesium is often anodized in dichromate solutions. The thickness of the coating depends on the amount of electricity passed through the cell. Thicknesses usually range from 0.0001 to 0.0008 inch (0.003 to 0.02 millimeter). Special treatments give the metal a porous outside layer that can absorb dyes. This makes it possible to produce colored surfaces that cannot be rubbed off or scratched.

Anodizing serves several purposes. For example, it forms a tough coating on the metal, makes a good electrical insulator, and resists corrosion. Anodized aluminum or magnesium can be used in airplanes, trains, and ships and on the outsides of buildings. Gordon H. Geiger

Anointing of the sick is a sacrament of the Roman Catholic Church and of Eastern Orthodox churches. A priest administers the sacrament to a person who is aged, seriously ill, or in danger of death from sickness or an accident. The sacrament may also be administered to a group, such as patients in a hospital. In the Roman Catholic Church, the sacrament was formerly called *extreme unction.* In administering the sacrament, the priest anoints a person's hands and forehead with holy oil. At the same time, prayers are said for the person's spiritual and physical healing. The prayers are based on the Epistle of James (5: 13-15). Richard L. Schebera

Anole, *uh NOH lee,* is the name of about 300 species of lizards that live in the West Indies and in Central and South America. One species, the *green anole,* is native to the Southern United States. This species is also called the *American chameleon,* but it is not a true chameleon (see Chameleon).

Most anoles grow to 8 inches (20 centimeters) long. They are generally green or brown and may have bright colors. Many species can change colors. Male anoles have a large, colorful throat flap called a *dewlap.* They fan their dewlap when they want to attract females or scare off rival males. Anoles live in shrubs, grasses, and trees and have toes suited for climbing. Each toe ends with an enlarged pad and a sharp claw. The pad has

Male anoles have large, colorful dewlaps.

thousands of hairlike bristles that stick to bark.

Anoles eat mainly small insects. A few large species also eat fruit. Most female anoles lay one egg approximately every few weeks during the breeding season.

Raymond B. Huey

Scientific classification. Anoles belong to the iguanid family, Iguanidae. They are genus *Anolis.*

Anorexia nervosa, *AN uh REHK see uh nur VOH suh,* is an emotional illness in which a person refuses to eat. It occurs chiefly among adolescent girls and young women. The word *anorexia* means *without appetite,* but anorexics may be extremely hungry most of the time. They avoid food for psychological reasons.

Some anorexics experience bouts of *bulimia*—an overwhelming craving for food—during which they consume large amounts of food. Afterward, they make themselves vomit. Some anorexics use laxatives or diuretics to eliminate food from the body. See **Bulimia.**

The chief physical symptom of anorexia nervosa is severe weight loss, involving more than 25 percent of the body weight. Other symptoms include low blood pressure, slow heartbeat, and growth of fine hair on the body. In adolescents, the start of puberty may be delayed. Female anorexics may not begin to menstruate, or their menstrual periods may stop. The disorder also affects the personality. Many anorexics isolate themselves from family and friends and may appear depressed. Most victims seem unaware of their condition. They consider themselves healthy, or even overweight.

Physicians disagree about the cause of anorexia nervosa. Some psychiatrists believe that anorexics try to starve themselves in order to avoid growing into adults. Other experts suggest that anorexics want to gain attention and a sense of being special.

Treatment for anorexia nervosa may include hospitalization, psychotherapy, and medication. Anorexics should be hospitalized if they suffer malnutrition. Some physicians recommend that the patient's family also undergo therapy. Most anorexics can be cured if they receive prompt treatment. However, the disease is fatal in some cases. Charles Michael Wuhl

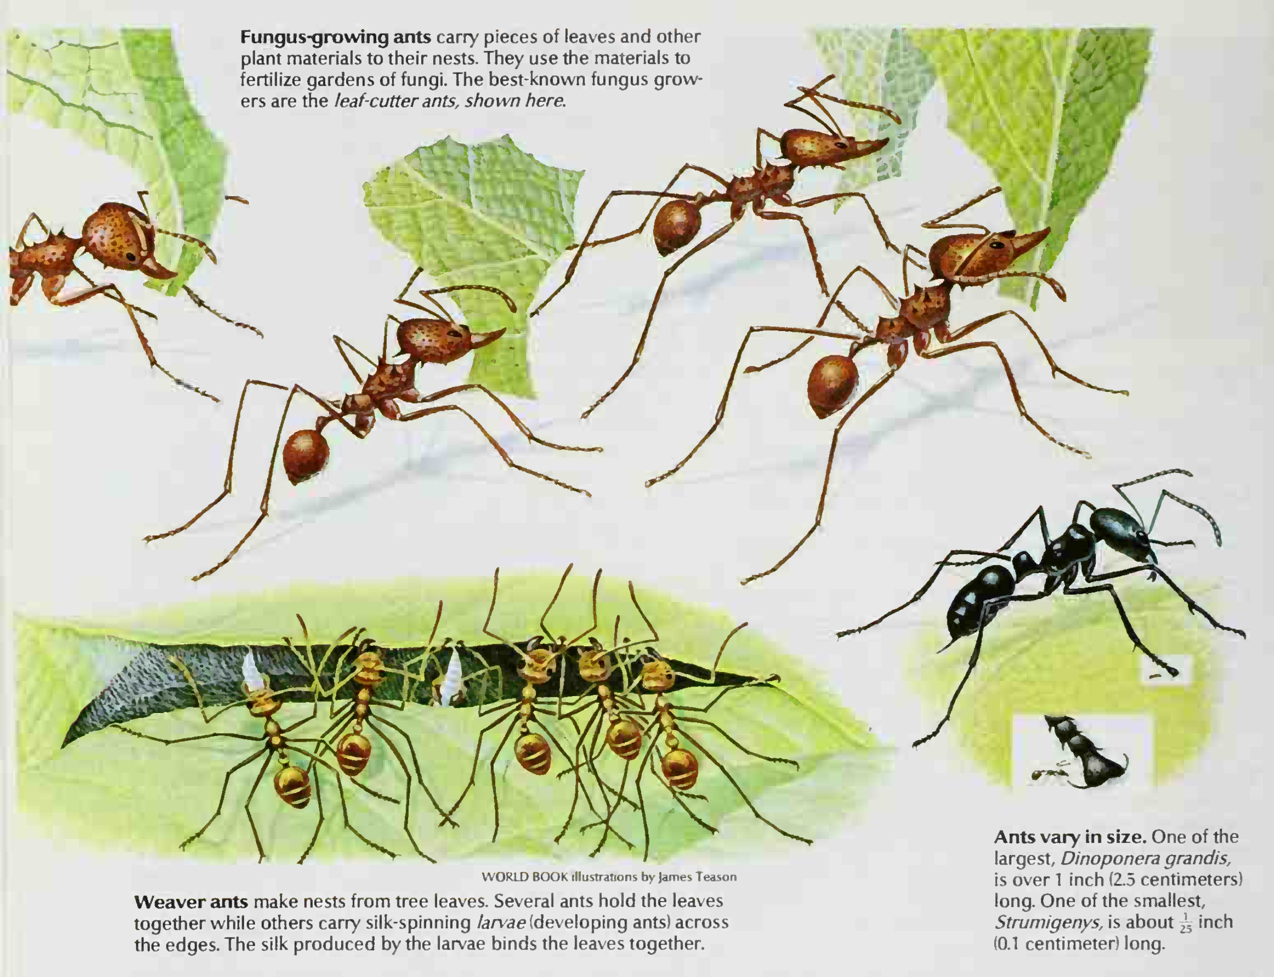
Anouilh, *ah NOO yuh,* **Jean,** *zhahn* (1910-1987), was a French playwright. Anouilh's plays explore matters of illusion and reality and conflicts between the individual and society. Many of them feature a sensitive and articulate young woman struggling to preserve her integrity in a corrupt, greedy world. His works are noted for polished dialogue and tight dramatic action.

Anouilh classified his plays according to their dominant mood. He called his tragic plays "black." One of his most famous "black" plays is *Antigone* (1944), a modern version of an ancient Greek myth. Anouilh used "grating" to describe his bitterly comic plays *Poor Bitos* (1956) and *The Waltz of the Toreadors* (1952). His lighter comedies were labeled "rose" or "pink" and "sparkling." They include *Thieves' Carnival* (completed in 1932, first produced in 1938), *Ring Round the Moon* (1947), and *The Rehearsal* (1950). Anouilh called his historical dramas "costumed" plays. His best-known "costumed" plays are *The Lark* (1953) and *Becket* (1959). Anouilh was born near Bordeaux. Felicia Hardison Londré

Anoxia, *an AHK see uh,* is the lack of a normal supply of oxygen to body tissues, or the inability of the tissues to use the oxygen. It is also called *hypoxia.*

Anoxic anoxia occurs when blood flowing through the lungs does not pick up enough oxygen. This can happen when there is a reduced amount of oxygen in the air, such as at altitudes above 10,000 feet (3,000 meters). The blood also can fail to pick up sufficient oxygen because of defects in the lungs or because of obstruction of the air passages involved in breathing. Rapid, deep breathing is a common symptom of anoxic anoxia. The condition is often accompanied by *cyanosis,* a bluish coloration of the skin. Severe cases may lead to loss of consciousness and even death.

Anemic anoxia occurs when the blood cannot carry its normal load of oxygen. This happens when the blood has insufficient amounts of *hemoglobin* (the substance that transports oxygen in the blood), or when the hemoglobin is altered by carbon monoxide or other poisons.



Stagnant anoxia develops when the blood flows so slowly that it loses most of its oxygen before completing its course through a tissue. Part of the tissue thus receives little or no oxygen. An example of stagnant anoxia occurs during cold temperatures when blood vessels under the fingernails and in the lips constrict, causing cyanosis in those body parts.

Histotoxic anoxia is caused by poisons that make the tissues incapable of using the oxygen supplied. Cyanide is such a poison. K. E. Money

See also **Oxygen.**

Anselm, Saint (1033-1109), was an influential medieval theologian and church leader. He became famous for his long essays *Monologion* and *Proslogion.* In both works, Anselm attempted to prove the existence of God through reason. His best-known argument, which appears in *Proslogion,* states that the existence of the idea of God necessarily means that God exists. Anselm also wrote *Cur Deus Homo.* This book argues that only the death of a God-man like Jesus Christ could fulfill the debt that sinful humanity owed to God.

Anselm was born in Aosta, Italy. He joined the Benedictine monastery of Bec in France in about 1060. There he studied with Lanfranc, a noted Italian monk and scholar. Anselm rose rapidly in the organization of the monastery and became the abbot in 1078. In 1093, he was appointed archbishop of Canterbury, the most important religious position in England. He held the post for the rest of his life. Anselm went into exile from 1097 to 1100 and again from 1103 to 1107 because he opposed the king's power to select church officials. Anselm's feast day is April 21. Marilyn J. Harran

Fungus-growing ants carry pieces of leaves and other plant materials to their nests. They use the materials to fertilize gardens of fungi. The best-known fungus growers are the *leaf-cutter ants, shown here.*

Ants vary in size. One of the largest, *Dinoponera grandis,* is over 1 inch (2.5 centimeters) long. One of the smallest, *Strumigenys,* is about $\frac{1}{25}$ inch (0.1 centimeter) long.

WORLD BOOK illustrations by James Teason

Weaver ants make nests from tree leaves. Several ants hold the leaves together while others carry silk-spinning *larvae* (developing ants) across the edges. The silk produced by the larvae binds the leaves together.

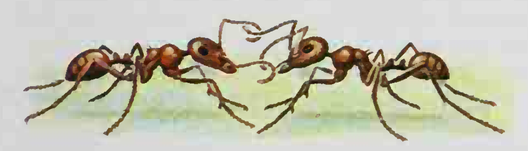
Ant

Ant is the name of a family of small insects that live in organized communities. Ants are therefore known as *social insects.* Other social insects include some kinds of bees, all termites, and certain wasps. However, ants are perhaps the most highly developed social insects.

A community of social insects is called a *colony.* An ant colony may have a dozen, hundreds, thousands, or millions of members. It may have one or many *queens.* A queen's chief job is to lay eggs. Most members of an ant colony are *workers.* All the workers, like the queens, are females. The workers build the nest, search for food, care for the young, and fight enemies. Males live in the nest only at certain times. The only job the males have is to mate with young queens. After mating, the males soon die.

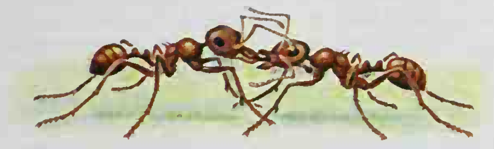
Ants have many different ways of life. For example, *army ants* live by hunting other insects. Some species of army ants march across the land in enormous swarms, eating most of the insects they meet. Ants known as *slave makers* raid the nests of other ants and steal the young, which they raise as slaves. *Harvester ants* gather seeds and store them inside their nests. Certain species of *dairying ants* keep insects that give off a sweet liquid when the ants "milk" them.

Ants live everywhere on land, except in extremely cold areas. They are most numerous in regions with a warm climate. Some species live in underground tunnels, and some build earthen mounds. Others live inside trees or in hollow parts of certain other plants. Still others construct their nests from tree leaves. Some species, such as army ants, do not have permanent nests.

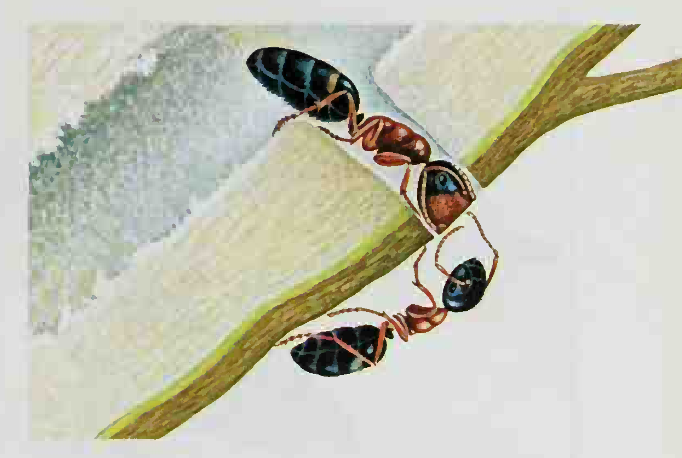


There are about 10,000 species of ants. Most species have drab colors, such as black, brown, or rust. But some are yellow, green, blue, or purple. Ants also vary greatly in size. The largest species are more than 1 inch (2.5 centimeters) long. The smallest are about $\frac{1}{25}$ inch (0.1 centimeter) long. Like most small insects, however, ants can lift objects several times heavier than their bodies. Some ants can lift things 30 times heavier than their bodies.

Scientists believe that ants gradually developed from wasps more than 100 million years ago. Ants resemble



Norman F. Carlin, the contributor of this article, is Lecturer on Biology at Harvard University.



Some ants build earthen mounds over their underground nests. The mounds of harvester ants, *above,* are a common sight in the Southwestern United States.

Ants use their antennae to smell one another. In this way, ants recognize nestmates. The antennae are organs of touch, taste, and hearing as well as of smell.

Ant nestmates share food by *regurgitation.* Two ants stand mouth to mouth, and one spits up food for the other. Food is shared among all members of a colony.

Some carpenter ants nest in tunnels in tree branches. Large workers are called *soldiers.* A soldier blocks the nest entrance with its pluglike head, *above,* to keep out enemies.

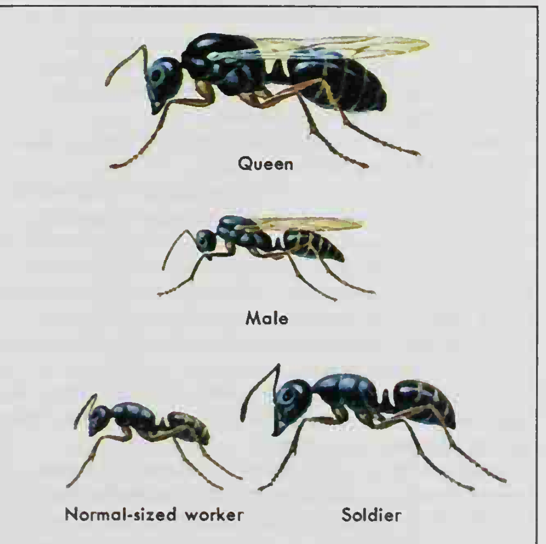
Fossils of ants indicate that ants have lived on the earth for more than 100 million years. This fossil ant, which became preserved in amber, is about 30 million years old.

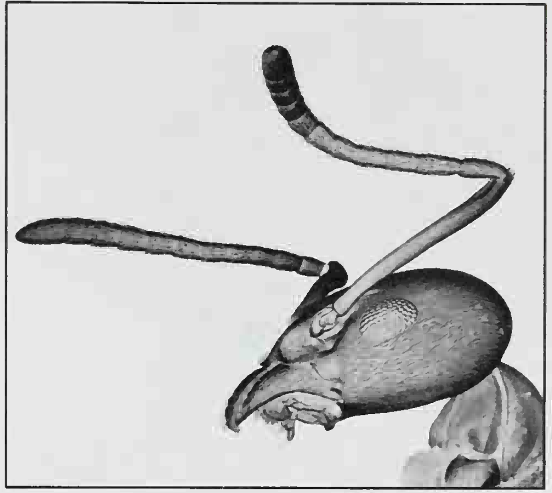
wasps more than they do any other insects. In fact, one kind of wasp looks so much like an ant that it is commonly called a *velvet ant.* But an ant has a *node* (knotlike growth) on top of its waist. This node distinguishes ants from most antlike wasps.



The bodies of ants

Among most species of ants, the queens, workers, and males differ in size. In many cases, the queens are several times larger than the workers. The males are larger than the workers but smaller than the queens. In addition, the workers of a particular species may differ in size. The largest workers are called *soldiers.*

Like other insects, ants have a hard, shell-like covering called an *exoskeleton.* This covering protects the internal organs. An ant's muscles are attached to the inside walls of the exoskeleton.



An ant's body has three main parts. They are (1) the head, (2) the trunk, and (3) the metasoma. An ant's internal organs and sense organs are similar to those of many other insects.

The head. The main features of an ant's head are the antennae, eyes, and mouthparts. The antennae and eyes are described in the section *Sense organs.* The mouthparts include the *mandibles* and the *maxillae.* The man-

An ant's head includes two antennae, a pair of many-lensed *compound eyes,* and a pair of jaws called *mandibles.* This highly magnified view shows the tiny lenses that make up a compound eye and the fine hairs and spines that cover the antennae.

dibles are a pair of jaws that move from side to side rather than up and down. Ants use their mandibles to grasp food, carry their young, and fight enemies. Many ants also use their mandibles to build nests by digging up soil or cutting through wood. The maxillae are a pair of structures that lie behind the mandibles. Ants use their maxillae to chew food into small particles. The food particles are then lapped up with the tongue and pass into a small pouch below the mouth opening. The pouch is lined with muscles that contract and so squeeze the liquid out of the food particles. Ants swallow the liquid and spit out the remaining pellet of solid food. Some tiny food particles may pass through the throat. Ants eat various kinds of foods, including insects and fruits and other parts of plants.

Each of an ant's maxillae has a comb, which consists of a row of tiny hairs. An ant cleans its front legs by drawing them across the combs.

The trunk is the middle part of an ant's body. A thin neck connects the head to the trunk.

An ant has three pairs of legs, which are attached to the bottom of the trunk. Each leg has nine segments connected by movable joints. The foot of each leg has two hooked claws. As an ant walks, the claws dig into the surface. The claws thus enable ants to climb trees and to walk on the undersides of limbs and leaves. Many ants use the claws on the front legs to dig up soil and tunnel underground.

On each front leg, an ant has two combs like those on the maxillae. An ant uses these combs to clean the other pairs of legs and the antennae.

Among most species of ants, the males and young queens have two pairs of wings attached to the trunk. They use their wings only once, at mating time. The workers do not have wings.

The metasoma has two parts, the *waist* and the *gaster.* The waist consists of one or two movable, beadlike segments. It connects the trunk to the gaster, the larger part of the metasoma.

Some ants have a poisonous sting at the tip of the gaster. Instead of a sting, certain other ants have a poison gland that lies inside the gaster and opens at the tip. These ants squirt poison at an enemy.

Internal organs. An ant's brain is connected to a nerve cord, which extends through the trunk and metasoma. Nerves branch out from the nerve cord to all parts of the body.

Ants have a simple heart shaped like a long tube. The tube extends from the head to the rear of the gaster. Muscle contractions force blood forward through the tube. The blood empties out of the tube near the brain. An ant does not have blood vessels. Instead, the blood flows from the head back through the body cavity, bathing all the tissues and organs. It then reenters the tube through small openings along the sides. The openings have valves that allow blood to enter the tube but prevent it from leaking out. An ant's blood is colorless.

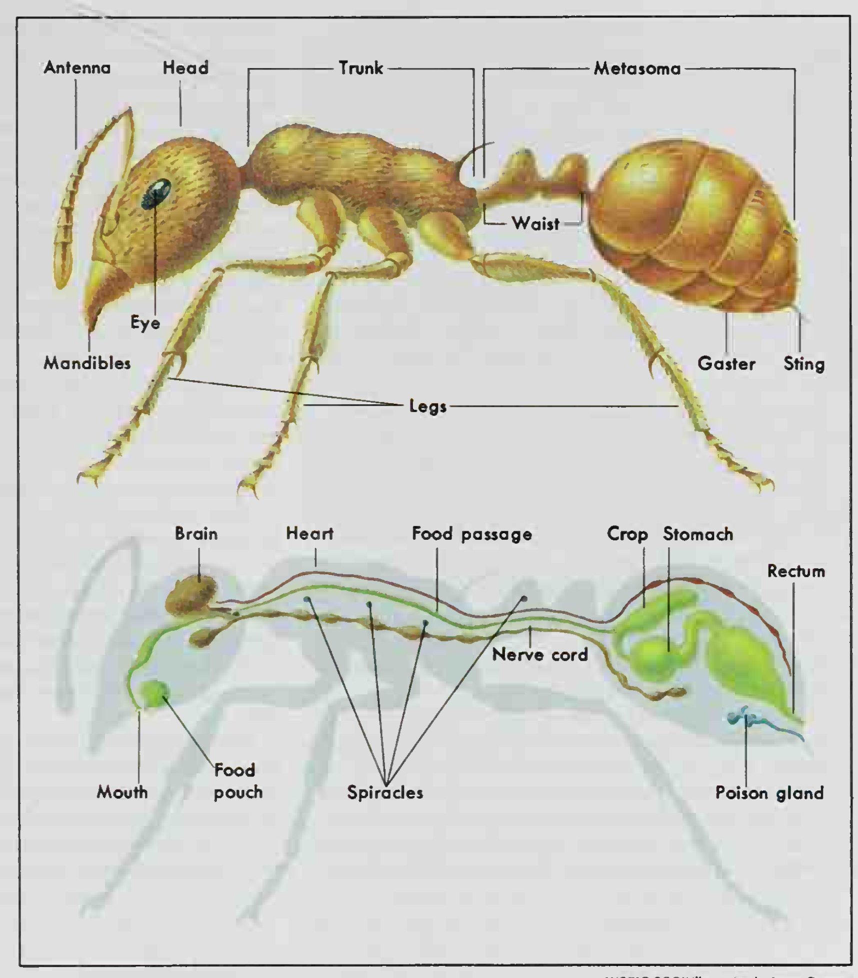
Ants do not have lungs. Instead, they have many air tubes that branch out to all parts of the body. Oxygen enters the tubes through tiny openings along the sides of the body. Carbon dioxide passes out of the body through the same openings.

An ant's digestive system consists basically of a tube that extends from the mouth to the end of the gaster. Near the front of the gaster, the tube forms an enlarged pouch, called the *crop.* The crop serves to store liquid food temporarily, not to digest it. The crop can expand greatly to hold food. It is also called the *social stomach* because an ant frequently *regurgitates* (spits up) some of the food stored in the crop and shares it with other ants. A valve separates the crop from the ant's "true" stomach. From time to time, some food is pumped from the crop into the stomach, where digestion occurs.

Sense organs. An ant's chief sense organs are its antennae. Ants have two antennae, which are attached to the front of the head. The antennae are organs of smell, touch, taste, and hearing. When an ant is active, the antennae move almost constantly. With their antennae, ants tap the ground, pick up scents in the air, examine pieces of food, and stroke one another. Ants use their antennae to find their way about, to search for food, and to recognize nestmates. Some researchers believe that all the ants within a colony have a distinctive odor and that ants may recognize their nestmates by that odor.

Ants have taste organs on the mouthparts, as well as on the antennae. They also have touch organs not only on the antennae but also on almost all other parts of the body. The touch organs consist of tiny hairs and spines.

Most ants have two *compound eyes,* one on each side of the head. Each eye consists of tiny lenses set close together. The number of lenses varies from fewer than 6 to more than 1,000, depending on the species. In most cases, the males and queens have more lenses than do the workers. Each lens registers an impression of only a small part of whatever an ant looks at. Impressions from all the lenses together form a picture that is broken up into bits. Compound eyes enable ants to see movements easily. However, ants can see clear images of only nearby objects. In addition to compound eyes, some species of ants have three simple eyes, called *ocelli,* on the top of the head. These simple eyes can only distinguish between light and dark. A few kinds of ants do not have any eyes.



The body of an ant

The external anatomy

An ant's body has three main parts: (1) the head, (2) the trunk, and (3) the metasoma. The main features of the head are the eyes, antennae, and mandibles. Three pairs of legs extend from the bottom of the trunk. The narrow front part of the metasoma is called the *waist,* and the large back part is called the *gaster.* Some ants have a sting at the tip of the gaster.

The internal anatomy

An ant's internal organs include a brain and nerve cord and a tube-shaped heart. The animal breathes through *spiracles* (tiny openings along the sides of the body). Its digestive system includes a food pouch that squeezes the liquid out of food. The liquid moves through a food passage to the *crop,* a storage pouch, and then to the stomach, where digestion occurs. Wastes pass through the rectum and out of the body.

WORLD BOOK illustration by James Teason

Ants lack ears. But they can hear by means of sense cells called *chordotonal organs.* These organs are on the antennae, legs, trunk, and head. The chordotonal organs respond to sound vibrations that pass through the ground or other solid matter. Researchers do not know for certain whether ants can hear sounds that pass through the air.

Some ants can make sounds by means of a *stridulatory organ* on the metasoma. In most cases, this organ consists of a row of ridges on one segment of the metasoma and a hard point on another segment. Ants make squeaky or buzzing sounds by rubbing the segments against each other. In some cases, the sounds are loud enough for people to hear.

Life in an ant colony

All ants are social insects. But except for the fact that they all live in groups, ants vary greatly in their ways of life. This section chiefly discusses the general features of life in an ant colony. The section *Kinds of ants* describes some of the many ways of life among ants.

Castes. In almost all ant colonies, the members are divided into three *castes* (classes)—the queen, workers, and males. In most cases, a young queen starts a new colony after mating with one or several males. After she has established a colony, the queen lays eggs for the rest of her life. The queen does not rule the colony. But the workers feed and lick her, as they do one another. Some colonies have only one queen. But in some species, there may be thousands of queens in a colony. Besides caring for the queen, the workers enlarge, repair, and defend the nest; care for the young; and gather food. A worker may chiefly do one job throughout its life or change jobs from time to time. Males do not do any work in the colony. They live a short time, and their only function is to mate with young queens.

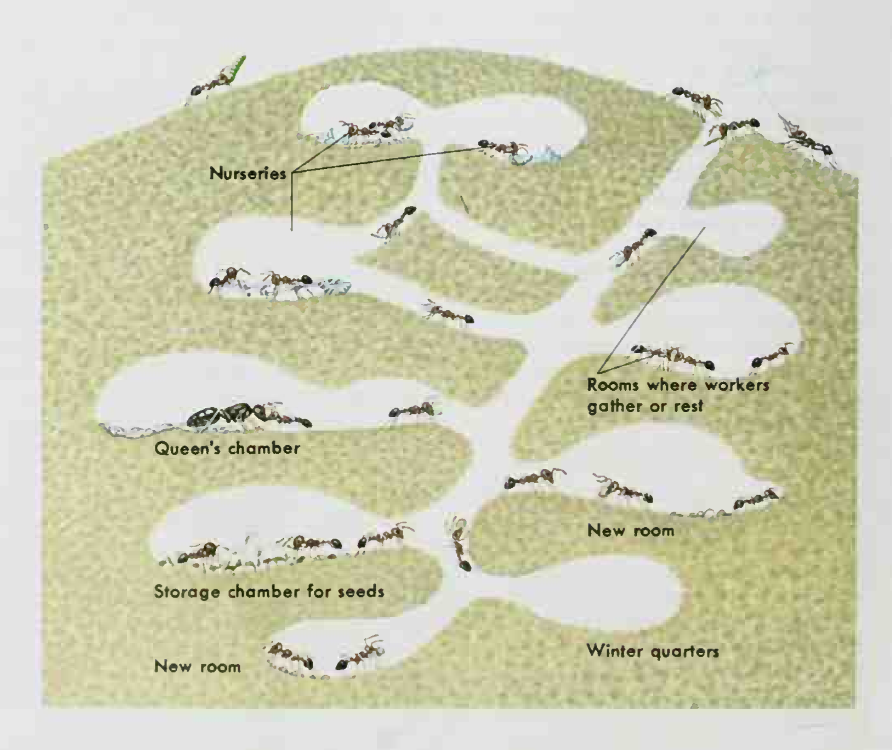
Among many species of ants, the workers differ in size and shape. The largest workers, the soldiers, have a big head and large mandibles. In some species, the soldiers' chief job is to defend the colony from enemies. In other species, the soldiers have no special job. Among certain *carpenter ants,* the soldiers have a blunt, plug-shaped head. Carpenter ants are large black or brown ants that make their nests in tunnels in the branches of trees. A soldier keeps enemies out of the nest by blocking the entrance with its head.

Nests. Most ant species make their nests underground, carving tunnels and chambers in the soil. Some of these species build large mounds of soil, twigs, and pine needles over their underground nests.

Carpenter ants make their nests in the trunks and branches of trees and even in the wooden beams of houses. These ants, unlike termites, do not eat wood. They chew tunnels in wood only to make nesting space. Many kinds of ants make their homes in rotten logs, under the bark of trees, or in hollow parts of the leaves or thorns of certain plants. Some species chew up plant fibers and use the material to build "cardboard" nests.

Tropical *weaver ants* construct nests from tree leaves. To make a nest, some of the workers hold the edges of leaves together, while other workers carry silk-spinning *larvae* back and forth across the edges. Larvae are ants in an early stage of development. The larvae produce a thick sheet of silken webbing that binds the edges of the leaves together.

Ant nests vary greatly in size. Some nests may have only one chamber no bigger than your finger. Such a nest may have as few as 12 ants or as many as 300. Some tropical ants build huge underground nests that may extend 40 feet (12 meters) below the surface of the ground. More than 10 million ants may live in such a nest. Some North American and European ants build nests that consist of 12 or more mounds connected by underground tunnels. The nesting site may cover an area the size of a tennis court, and some mounds may be 3 feet (0.9 meter) high or higher. Millions of ants may live in the mounds and underground chambers.



Most ant nests have a number of chambers. One chamber houses the queen and her eggs. Several other chambers serve as "nurseries," to which the workers move the growing young. If one chamber becomes too cold or too wet for the young, the workers move them to a warmer or drier chamber. Many chambers serve as gathering or resting places for the workers. The nests of some ants have rooms in which food is stored or fungi are raised. As a colony grows, the workers enlarge the nest by making more rooms and passageways. Ants that live in regions with cold winters move to the deepest parts of their nests during the winter. They emerge from their nests again in spring.

Reproduction. Many queens lay thousands of eggs in a lifetime. The vast majority of the eggs develop into workers. After the colony is established, the queen begins to lay some eggs that develop into males and young queens. A few weeks after they reach adulthood, the males and the young queens of most species leave their nests and go on a *mating flight.* They fly in a swarm high in the air and mate.

During mating, a male deposits *sperm* (male sex cells) inside a queen's body. A young queen may mate with one or more males. She receives her lifetime supply of sperm during the mating flight. The sperm are stored in the queen's gaster. They enter her eggs as she lays them.

After mating, the male and queen ants land on the ground. The male wanders off and dies. The queen tears off her wings and begins to search for a nesting site. In some cases, the queen returns to her colony, where she is accepted as an extra queen. Among parasitic ants, the queen takes over the nest of another species of ant. She depends on these ants to care for her and her eggs. But among most kinds of ants, the queen establishes a new nest.

After the queen prepares a nest, she seals the entrance. She soon begins to lay eggs. During this time, the queen lives off her body fat. She also gets some nourishment from her now useless wing muscles, which dissolve into nutrients that enter the bloodstream. In addition, the queen may eat some of her eggs.

Inside an ant nest

This drawing shows the nest of a colony of harvester ants. The nest consists of various rooms and connecting tunnels. The tunnels extend through the mound and deep underground. One chamber houses the queen and her eggs. Several rooms serve as "nurseries," where the workers care for the growing young. Some chambers are gathering or resting places for the workers. Harvester ants also have rooms for storing seeds, which they gather outside the nest. As a colony grows, the workers make more rooms and tunnels. The ants spend the winter in the deepest rooms of the nest.

WORLD BOOK illustration by James Teason

Among certain kinds of hunting ants, the queen may leave the nest from time to time and catch insects to eat. But among most species, she does not leave the nest.

Ants go through four stages of development: (1) egg, (2) larva, (3) pupa, and (4) adult. Ant eggs are very tiny. They hatch within a few days and become larvae. The larvae are white, wormlike creatures. Most larvae cannot move about. The queen feeds the larvae with her saliva and with some of her eggs. In general, the larval stage lasts a few weeks. After the larvae complete their growth, they become pupae. The larvae of some species spin a cocoon of fine silk around themselves before becoming pupae. The pupae of other species are covered only by their transparent skin. The pupae lie motionless and do not eat. They slowly take on the form of adult ants. In most cases, the pupal stage lasts about two or three weeks. Then, an adult ant emerges from the cocoon or skin.

The first worker ants to become adults leave the nest and bring back food for the queen and the larvae. The workers take over the care of the *brood*—the eggs, larvae, and pupae—and the queen continues to lay eggs.

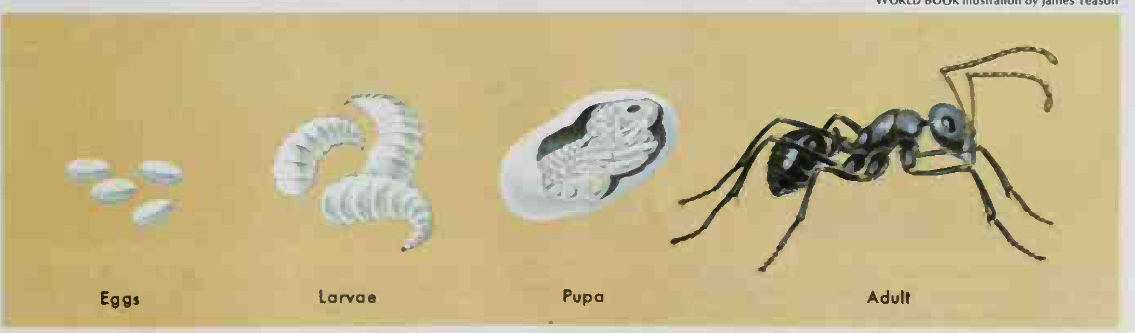
Protection against enemies. Anteaters, spiders, frogs, toads, lizards, birds, and many kinds of insects prey on ants. In most cases, ants from different colonies, even if they are of the same species, treat one another as enemies. Ants protect themselves against their enemies by stinging or biting.

About half of all species of ants have a sting. The stings of such ants as *fire ants* and *bulldog ants* can pierce the skin. The sting releases a painful poison. Certain ants have a sting that cannot penetrate tough skin. But the sting is an effective defense against other insects. It releases a poison containing an insect-repelling gas. The poison is also thick and gluey. It can gum up the antennae, legs, or jaws of another insect. Some ants that lack a sting can spray poison from the tip of the gaster.

Worker ants from different colonies often fight one another when they meet. Some fights do not result in serious injuries. For example, *honey ants* of rival colonies have shoving matches in which the workers do not hurt one another. But the victors may take over the nest of the defeated colony. Some ants have fierce battles that result in death. In these battles, ants use their jaws to grab enemies by a leg or an antenna. Often, several nestmates grab the legs and antennae of an enemy ant and hold the victim stretched out. Other nestmates may join the fight and tear the victim apart with their jaws. Some ants fight huge, grim wars in which thousands of ants rip one another to pieces. The winners may invade the nest of the defeated colony and carry off the brood, which they eat. Some species of ants live entirely by robbing the nests of other ants in this way.

John R. Conway

Reproduction. This large queen honey ant is laying eggs, which the nearby workers will care for. In time, the developing young will be enclosed in cocoons like the three shown here.



Communication. Ants communicate with one another in various ways. Ants that live inside plants or in leaf nests may tap their gasters against the outside walls of the nest when they discover food or an enemy nearby. The taps send vibrations through the nest walls, arousing the ants inside. The ants may then rush out and help carry in the food or fight the enemy. Ants that have a stridulatory organ arouse their nestmates by producing squeaky or buzzing sounds with the organ.

Ants also communicate with one another by giving off chemicals called *pheromones.* These chemicals are produced by glands that open at certain places in the head, trunk, and metasoma. They have a distinctive smell or

The life cycle of ants

Ants develop in four stages: (1) egg, (2) larva, (3) pupa, and (4) adult. Ant eggs hatch within a few days into larvae. The larval stage lasts a few weeks. In some species, the larvae spin a cocoon before becoming pupae. The pupal stage lasts about three weeks. The adult ant then emerges.

WORLD BOOK illustration by James Teason

taste to which ants are sensitive. The various kinds of pheromones communicate different information. By releasing pheromones from the tip of the gaster, for example, an ant may lay a scent trail from a new food supply to its nest. The ant then arouses the other workers, which follow the trail to the food. To warn nestmates of danger, ants can give off "alarm" pheromones.

Ants probably distinguish members of their colony from enemies by odor. When two ants meet, they smell each other with their antennae. If they are nestmates, the two ants may stand mouth to mouth. One ant then regurgitates a drop of liquid for the other.

Life span. Queen, worker, and male ants have different life spans. Queens live the longest, from about 10 to 20 years. Workers may live from less than 1 year to more than 5 years. Males live only a few weeks or months before the mating flight, after which they soon die.

Kinds of ants

There are about 10,000 species of ants. *Entomologists* (scientists who study insects) classify ants into eight or nine groups, based on similar physical features. But ants can also be grouped according to their ways of life. This section discusses six groups of ants with different ways of life. The groups are (1) army ants, (2) slave makers, (3) harvester ants, (4) dairying ants, (5) honey ants, and (6) fungus growers. Each group includes many species.

Army ants are fierce hunters. Most species travel across the land in narrow columns. Others hunt underground, moving through tunnels in the soil. Army ants prey chiefly on other insects and spiders. But in some cases, they also kill and eat larger animals that cannot escape quickly.

Most army ant colonies have from 10,000 to several million members. Army ants that live aboveground do not build permanent nests. When they rest, they cling together in a large cluster. They may hang from a tree branch or lie inside a hollow log or another suitable place. The queen and her brood lie within the large cluster of bodies.

Some kinds of army ants hunt for a few weeks and then rest for a few weeks. During the hunting periods, they may nest at a different site every night. During the resting periods, they stay in one place, and the queen lays hundreds or thousands of eggs.

The name *army ants* is used to describe both *legionary ants* and *driver ants*. Legionary ants live in North and South America. Those that live in cooler regions have smaller colonies than do the tropical species, and they hunt chiefly at night. Driver ants live in the tropical regions of Africa.

Slave makers attack the nests of other ants to kidnap the pupae. After the pupae become adults, they act as though the slave makers' nest were their own. They thus help with the work of the colony. Some kinds of slave makers can survive without slaves. But slave makers known as *Amazon ants* cannot. Their mandibles are so long and curved that they cannot feed themselves or dig nests. Amazon ants need slaves to feed them and to work for them.

After the mating flight, a young slave maker queen does not start a new colony. Instead, she takes over a nest of another species. She kills or drives away many of the workers and may kill the colony's queen. The slave maker queen stays with the colony's brood until they reach adulthood. These ants then treat her as they would their own queen. In time, the eggs of the slave maker queen develop into adult workers. They bring more slaves into the nest by raiding other nests. Slave makers live in cool regions of North America, Europe, and Asia.

Harvester ants collect seeds and store them in special chambers in their nests. They thus always have a supply of food available. The ants tear off the husks of the seeds and chew the kernels into a soft pulp called *ant bread*. They then squeeze out the liquid and swallow it. Some kinds of harvester ants also eat flowers, fruits, and insects.

Harvester ants live on all the continents except Antarctica. Some species have large colonies of 60,000 to

Army ants are fierce hunters that travel in swarms and prey chiefly on other insects. These army ants are attacking a grasshopper. The ants bite the victim with their long mandibles.

Edward S. Ross

Slave makers raid the nests of other ants and carry off the pupae, *shown here*. After the pupae become adults, they help with the work in the slave makers' colony and so serve as "slaves."

90,000 members. The mounds built by colonies of harvester ants are a common sight in the Southwestern United States.

Dairying ants live chiefly on a sugary liquid called *honeydew.* They obtain honeydew from certain insects, particularly aphids and other plant lice. Plant lice suck juices from plants. These juices contain more sugar and water than the lice need, and they discharge the excess as honeydew. Dairying ants visit the plants on which the lice feed so that they can lick up the honeydew. In many cases, a plant louse will release a drop of honeydew whenever an ant "milks" the insect by stroking it with its antennae. The ants protect the lice by fighting insects that come near while the ants are feeding.

Some kinds of dairying ants keep the eggs of plant lice in their nests during the winter. In spring, the eggs hatch, and the ants carry the plant lice out of the nest and place them on plants.

Certain species of dairying ants tend "herds" of plant lice that feed on roots inside their nests. Among these species, the young queens carry an egg-laying plant louse between their jaws when they leave the nest and go on the mating flight. After a queen digs her new nest, she places the louse on a root and starts a new "herd."

Some kinds of aphids and other plant lice feed on crops and cause great damage. Because dairying ants protect the aphids, they are considered agricultural pests. For example, *Argentine ants* are considered agricultural pests in California and northern Florida, where they infest orange groves. These dairying ants are native to Argentina. Dairying ants live on every continent except Antarctica.

Honey ants, also called *honeypot ants,* gather honeydew from insects or from plants and store it in their nests. Certain workers, called *repletes,* serve as living storage tanks for the colony. The workers that gather the honeydew feed it to the repletes after returning to the nest. The gaster of a replete becomes so swollen with honeydew that the ant cannot walk. It hangs motionless from the ceiling of a chamber in the nest and regurgitates some honeydew whenever a nestmate taps it with its antennae. Honey ants live in dry, warm regions throughout the world, including parts of the Western United States.

Edward S. Ross

Dairying ants "milk" honeydew from aphids, *above.* The aphids release drops of honeydew whenever the ants stroke the insects with their antennae. The ants then lap up the sugary liquid.

Fungus growers cultivate gardens within their nests. They raise various kinds of moldlike or yeastlike fungi. The fungi produce tiny, nourishing knobs, which the ants eat. The ants fertilize their gardens with leaves, flower petals, and other plant materials that they gather from outside the nest. When a young queen goes on the mating flight, she carries along a pellet of fungus. After the queen prepares her nest, she starts a new garden with the pellet. She fertilizes the garden with her body wastes. Fungus growers live only in North and South America, and they are most plentiful in tropical areas.

Perhaps the best-known and most interesting fungus

Ross E. Hutchins

Harvester ants store seeds in special chambers inside their nests, *above.* The ants tear off the husks and chew the kernels into a soft pulp. They then squeeze out the liquid and swallow it.

John R. Conway

Honey ant workers called *repletes* serve as storage tanks. They store honeydew in their gasters, which expand greatly. The repletes feed the liquid to nestmates.

growers are the *leaf-cutter ants.* They build huge underground nests in which millions of ants may live. At night, columns of workers leave the nest and cut pieces of leaves from trees, shrubs, and other plants. They carry the leaf fragments back to the nest, holding them above their heads. The ants look as though they are carrying parasols, and so they are sometimes called *parasol ants* or *umbrella ants.* Inside the nest, the ants chew the leaves into a pulp, which they place on the fungus gardens. Leaf-cutter ants are serious agricultural pests in parts of South America because they strip leaves from crops. In Brazil, colonies of leaf-cutter ants sometimes strip all the leaves from an orange grove in one night.

Keeping an ant farm

You can study a colony of ants as they work, eat, and care for their young by keeping an *ant farm.* An ant farm is a container made of a transparent material through which the chambers of the ants' nest are visible. You can purchase a commercial ant farm with a certificate that you exchange for live ants. The ants you receive generally consist entirely of workers. Without a queen, your ant farm will not be permanent. The worker ants will live for a month or two.

You can also make your own ant farm. To make one, fill a large, clean glass jar halfway with dry soil. Stock the jar with ants from a single nest. Collect eggs, larvae, and pupae by digging into the soil. Gather the workers in a plastic bag. Putting the ants in the refrigerator for half an hour will make it easier to transfer them to the jar. Put a fine wire screen over the mouth of the jar. Keep the jar covered when you are not watching the ants.

Feed the ants every few days, using honey mixed with water. Once a week, add some peanuts or a dead fly or cockroach. Remove unused food, or it will spoil. Moisten the soil in the jar every few days. Release your ants at their nest entrance after you have observed them for a few weeks.

Edward S. Ross

Leaf-cutter ants are major agricultural pests in parts of South America because they strip the leaves from crops. This leaf-cutter ant is using its mandibles to cut a piece of a leaf from a plant. The ant will then carry the fragment to its colony's nest, where it will be used to fertilize a garden of fungi.

The importance of ants

Ants play an important role in the balance of nature. They eat large numbers of insects and so help keep them from becoming too plentiful. In the tropics, for example, ants eat more than half the termites hatched each year. Ants, in turn, are an important food source for birds, frogs, lizards, and many other animals. See **Balance of nature**.

Ants are both beneficial and harmful to farmers. Some species aid farmers by killing insects that damage crops. Ants that dig underground nests improve the soil by breaking it up, loosening it, and mixing it. Loose soil absorbs water more easily than does hard-packed soil. Ants can also be agricultural pests. Some dairying ants protect aphids and other insects that harm crops. *Fire ants* are serious pests in the Southern United States. They build large mounds that interfere with the cutting of hay. They also have a painful sting, to which some people are allergic.

Many kinds of ants are household pests. For example, carpenter ants damage houses by tunneling through wooden beams. *Pharaoh's ants* and *thief ants* invade houses, restaurants, hospitals, and other buildings and eat stored food. Poison sprays or baits can sometimes help rid ants from houses. But before using indoor sprays or baits, a person should check with the state or county agricultural extension office to make sure they are both effective and safe to use. Norman F. Carlin

Scientific classification. Ants, bees, sawflies, and wasps make up an order of insects called Hymenoptera. Ants make up the family Formicidae.

Ant lion is an insect *larva* (immature form) that digs a pit in the soil to trap ants and other small insects for its food. The adult insect looks like a dragonfly. The ant lion larva is often called the *doodlebug.*

The ant lion has a plump, hairy body. A pair of sword-shaped jaws extends from its narrow head. Three pairs of legs are fastened to the body, close behind the head. The ant lion can walk only backwards.

The ant lion usually chooses a place with dry, sandy soil for its pit. It starts to work by walking around and around backwards, pushing its tail like a shovel down into the sand behind it. The sand slides up over the ant lion's broad back and toward its head. By jerking its head suddenly, the ant lion throws the sand to one side. It moves in smaller and smaller circles until it reaches the center of the circle. Then it has formed a funnel-shaped hole in the earth. This pit sometimes reaches as much as 2 inches (5 centimeters) across and 1 inch (2.5 centimeters) deep or deeper.

Edward S. Ross

Ant lion

The ant lion traps its prey by hiding under the sand at the bottom of the pit. If an ant crawls close to the edge of the pit, the soft sand slides away under its feet, and the ant falls into the pit. The ant lion then kills it with its jaws and sucks the juices from its body. Sandra J. Glover

Scientific classification. Ant lions belong to the order Neuroptera. They make up the ant lion family, Myrmeleontidae. There are hundreds of species.

Antabuse. See Disulfiram.

Antacid is any of a group of drugs that neutralize acid in the digestive system. Hydrochloric acid, produced in the stomach, is important to digestion. However, it can cause pain when it comes in contact with *peptic ulcers,* sores that can occur in the lining of the esophagus, stomach, or *duodenum* (first part of the small intestine). Antacids help relieve or prevent pain associated with peptic ulcers by neutralizing this acid. People also take antacids to stop the pain of heartburn and indigestion.

Many antacid products contain compounds of aluminum, magnesium, or, often, both. These chemicals react with acids to form more neutral compounds that do not irritate peptic ulcers. By relieving irritation, antacids also can help promote healing of the ulcers. Many doctors recommend their use along with other antiulcer drugs, such as antibiotics and histamine H2-receptor antagonists (for example, cimetidine).

Antacids come in tablet, capsule, and liquid form. Commonly used antacids include such brand-name products as Maalox and Mylanta. Tums, another common antacid, contains a compound of calcium that is helpful for digestion but not recommended for ulcer treatment.

These drugs ordinarily do not cause harmful side effects, and a doctor's prescription is not needed to purchase them. However, antacids that contain magnesium hydroxide can cause diarrhea, while those with aluminum hydroxide can cause constipation. Problems also may develop when antacids are used for long periods. For example, extensive use of antacids that contain calcium carbonate can cause too much calcium to accumulate in the body. High calcium levels can lead to kidney damage and other problems. N. E. Sladek

Antakya. See Antioch.

Antananarivo, *AHN tuh NAH nuh REE voh* (pop. 800,000), is the capital and largest city of Madagascar, which includes the island of Madagascar and small nearby islands. Antananarivo, formerly called Tananarive, is near the center of the island of Madagascar. For location, see **Madagascar** (map). It lies on a mountain ridge that runs across the island from north to south. Railroads running along the ridge link Antananarivo with the rest of the island and bring crops to the city for processing.

The majority of people who live in Antananarivo are of Indonesian descent. They are members of the Merina and Betsileo ethnic groups. Some of Antananarivo's residents are French. Madagascar was once a French colony. The French work with the local people in government, university education, and international trade. The University of Madagascar and several scientific research institutes are located in the city. Antananarivo's most famous building is the palace of the last queen of Madagascar's Merina kingdom. Built in the 1800's, the palace was destroyed by fire in 1995. Restoration began on the building shortly after the fire. Bruce Fetter

See also **Madagascar** (picture).

Antarctic. See Antarctica.

Antarctic Circle, *ant AHRK tihk* or *ant AHR tihk,* is an imaginary line that encloses almost all of Antarctica. Points on the Antarctic Circle lie at 66°30′ south latitude, about 1,624 miles (2,613 kilometers) from the south geographic pole (see **Antarctica** [map]).

The Antarctic Circle marks the edge of an area where the sun stays above the horizon one or more days each year. The sun never sets on the Antarctic Circle during the longest day of summer, about December 21. The sun never rises on the shortest day of winter, about June 21. If the South Pole at 90° south latitude were at sea level instead of nearly 10,000 feet (3,000 meters) above sea level, and if no atmospheric phenomena or other obstacles affected observations, the sun would be visible 90 days before and 90 days after the longest day of summer. It would stay below the horizon for the same time before and after the shortest day of winter.

Antarctica's rugged coast features jagged mountain peaks and glacier-filled valleys. Ice and snow cover 98 percent of the continent. Antarctica is the world's coldest region.

Antarctica

Antarctica, *ant AHRK tih kuh* or *ant AHR tih kuh,* is the ice-buried continent that covers and surrounds the South Pole. This dry and nearly barren land forms the coldest and iciest region in the world. It is colder than the region around the North Pole. The South Pole lies near the center of the Antarctic continent, on a high, windy plateau of ice and snow. The North Pole is in the center of the Arctic Ocean.

Antarctica covers about 5,400,000 square miles (14,000,000 square kilometers). It is larger in area than either Europe or Australia. Nearly all of Antarctica is covered with two thick ice sheets, one on either side of the Transantarctic Mountains. This icy layer, which averages approximately 7,100 feet (2,200 meters) thick, makes Antarctica the highest continent in terms of average elevation. The average elevation of Antarctica is 7,500 feet (2,300 meters) above sea level.

Stormy waters of the Atlantic, Indian, Pacific, and Southern oceans isolate Antarctica from the other continents. Ships must steer around towering icebergs to reach the continent. Planes that fly there must land on runways of solid ice.

Temperatures in Antarctica almost never rise above 32 °F (0 °C). Scientists recorded the world's lowest temperature, −128.6 °F (−89.2 °C), at Vostok Station, on July 21, 1983. Strong, bitter winds also chill the air. Antarctica's inland plateau has one of the driest climates on Earth. It gets no rain and hardly any new snow each year.

Only a few small plants and insects can survive in

Wendy Lawson, the contributor of this article, is Senior Lecturer of Geography at the University of Canterbury in New Zealand. She specializes in the study of glaciers and ice mass movements, and she has written extensively about Antarctica.

Facts in brief

Area: About 5,400,000 mi² (14,000,000 km²). *Greatest distance*—Antarctic Peninsula to Wilhelm II Coast, about 3,450 mi (5,550 km). *Coastline*—about 19,800 mi (31,900 km).

Elevation: *Highest*—Vinson Massif, 16,864 ft (5,140 m) above sea level. *Lowest*—sea level.

Physical features: *Chief mountain ranges*—Antarctic Peninsula, Ellsworth, Prince Charles, Transantarctic, Whitmore. *Chief glaciers*—Beardmore, Lambert, Rennick, Support Force. *Chief ice shelves*—Amery, Filchner, Larsen, Ronne, Ross.

Interesting facts about Antarctica

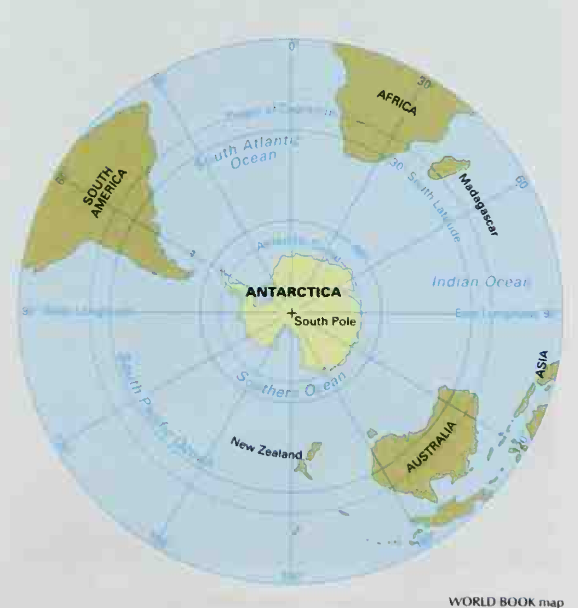
The krill—a small, shrimplike animal—is a key source of food in the Antarctic region. Such animals as fish, birds, and seals feed on krill and are, in turn, eaten by larger animals. Swarms of krill form huge red masses in coastal waters during the day and glow bluish-green at night.

Antarctica's wandering pole, officially called the *south magnetic pole,* moves at least 5 miles (8 kilometers) a year. This is the South Pole indicated by compass needles.

Thick ice buries most of Antarctica. The continent's deepest ice is more than 10 times the height of the Sears Tower, one of the world's tallest buildings.

Plant fossils found in Antarctica reveal that the continent once had a warm, ice-free climate with trees and other leafy plants.

First to reach the South Pole was Roald Amundsen, a Norwegian explorer. His expedition set off from Antarctica's Bay of Whales on Oct. 19, 1911, and reached the pole on Dec. 14, 1911.



WORLD BOOK illustrations by Paul D. Turnbaugh

Antarctica's dry interior. But various animals thrive in and near the surrounding waters, including fish, krill, seals, whales, penguins, and other sea birds.

Long before Antarctica was discovered, ancient Greek philosophers believed that a continent covered the southern end of Earth. Antarctica was first sighted in 1820. During the mid-1800's, explorers sailed along its coast and learned that it was large enough to be called a continent. Inland exploration began in the early 1900's. The Norwegian explorer Roald Amundsen reached the South Pole in 1911. In what turned out to be a dramatic race, he arrived there five weeks ahead of a British expedition led by Captain Robert F. Scott.

During the mid-1900's, U.S. Navy officer Richard Byrd led air expeditions that increased scientific interest in Antarctica. In 1959, officials of 12 countries signed an international agreement called the Antarctic Treaty. This treaty provides that the continent be used mainly for research and other peaceful purposes.

Today, scientists maintain year-round research stations in Antarctica. Activities on the continent encourage international cooperation and the sharing of scientific knowledge. Several countries have claimed parts of the continent. But the Antarctic Treaty places a freeze on existing claims and prohibits new ones.

WORLD BOOK map

Antarctica is the continent that covers the South Pole. The Southern Ocean surrounds the continent.

Land and climate

Ice and snow cover 98 percent of the Antarctic continent. High mountain peaks and a few other bare rocky areas make up the only visible land. Underneath the ice, Antarctica has mountains, lowlands, and valleys—much like the landforms of other continents.

The Southern Ocean surrounds Antarctica. The northern boundary of the ocean is 60° south latitude. Farther north, at about 55° south latitude, lies the center of an irregular band of water, the Antarctic Convergence, which is about 25 miles (40 kilometers) wide. Within that band, cold southern waters meet warmer, saltier northern waters. At about 50° south latitude is the massive *Antarctic Circumpolar Current* (ACC). The ACC flows from east to west around Antarctica.

Geologists believe Antarctica originally belonged to a giant supercontinent called *Gondwanaland.* This supercontinent also included Africa, Australia, India, and South America. By about 140 million years ago, the supercontinent had begun to break apart. The parts gradually drifted to their present locations, and Antarctica became a separate continent.

Many millions of years ago, Antarctica was an ice-free continent. Scientists have found fossils of trees and of dinosaurs and small mammals that once lived there. Glaciers began to form around the South Pole approximately 38 million years ago. They grew rapidly about 13 million years ago, forming the thick layers of ice and snow known as the Antarctic ice sheets. The ice sheets have buried almost all of Antarctica for the last 5 million years.

The Antarctic ice sheets are two thick layers of ice and snow that together cover most of the continent. They formed from layers of snow that were pressed together over millions of years. Air between the grains of snow was pushed out or trapped in bubbles as the buried layers hardened into ice. The air trapped in bubbles is an important source of information about past climates.

Michael Parfit

Mount Erebus, Antarctica's most active volcano, towers above Ross Island. In the foreground, a scientist builds an igloo from blocks of snow as part of his survival training.

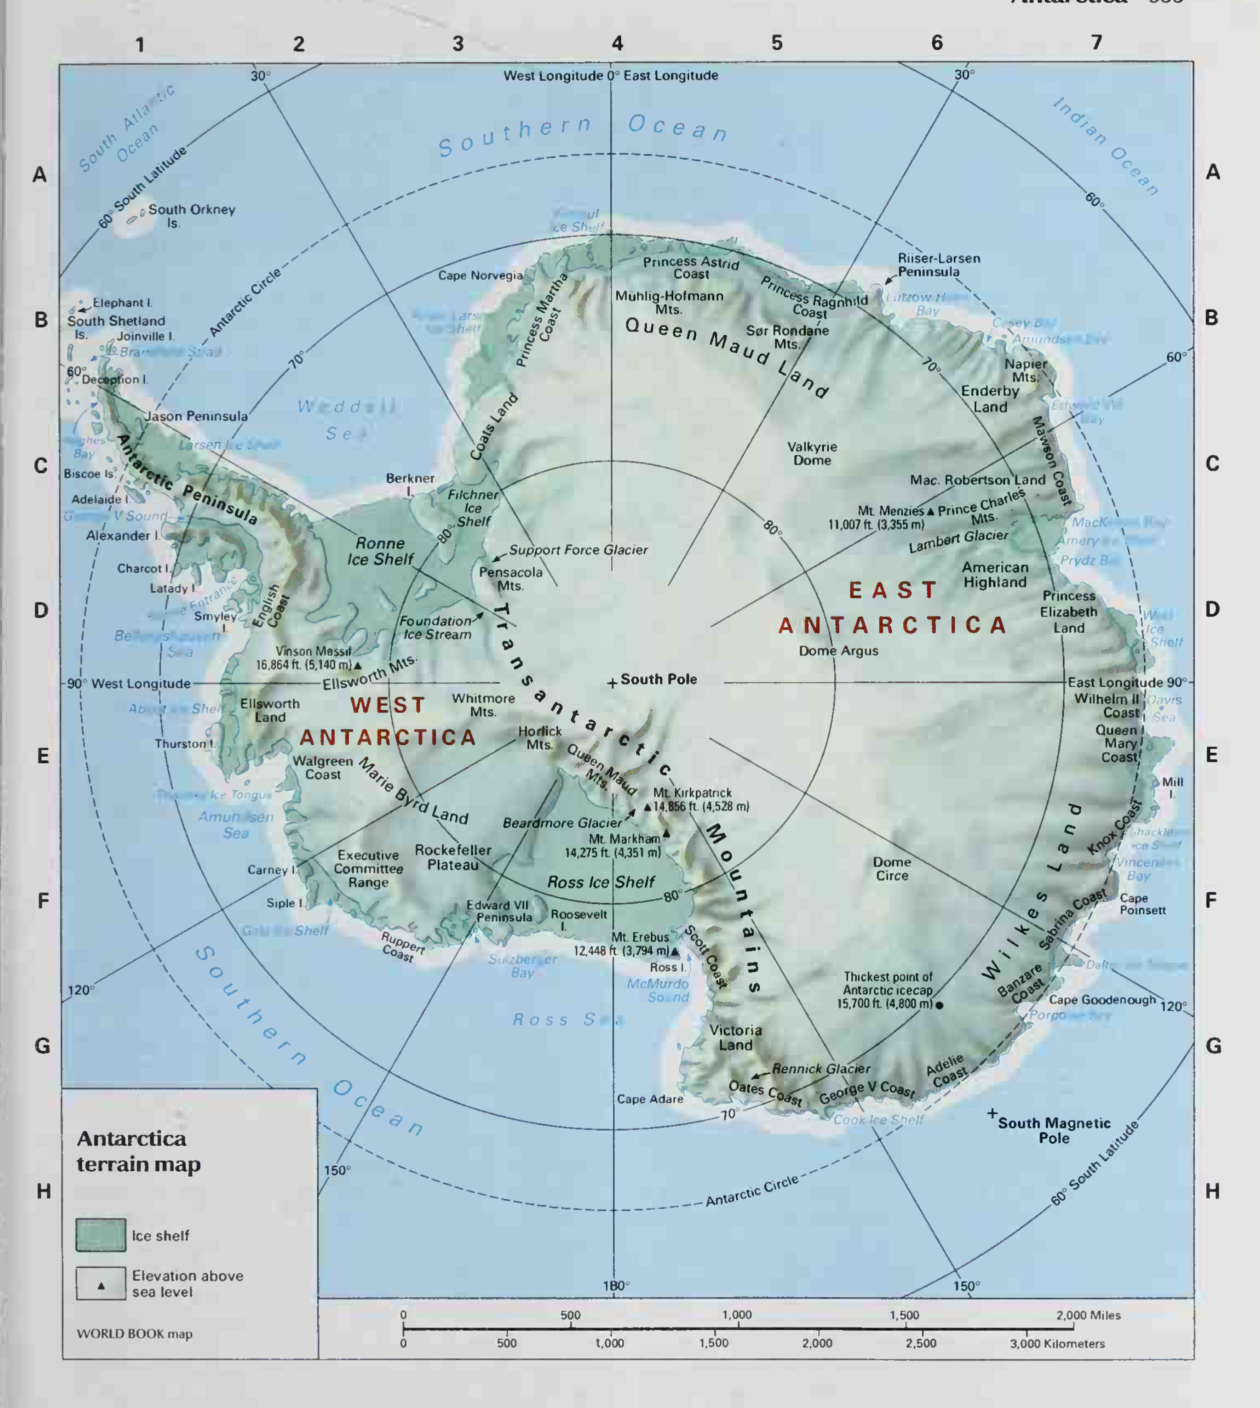
Today, the Antarctic ice sheets form the largest body of fresh water or ice in the world. Their volume of $7\frac{1}{4}$ million cubic miles (30 million cubic kilometers) represents approximately 70 percent of the world's fresh water. If the ice melted, Earth's oceans would rise nearly 230 feet (70 meters) and flood coastal cities around the world.

The thickest parts of the ice sheets are over deep basins that dip far below sea level. In those areas, the ice is as thick as 11,500 feet (3,500 meters). The ice reaches its highest point over a mountain peak, where it rises about 13,500 feet (4,100 meters) above sea level.

The weight of the ice sheets causes the ice to spread outward and flow toward the coasts. Ice near the coasts moves as much as 660 feet (200 meters) a year. Glaciers in narrow valleys move even more quickly. In some areas, the ice sheets break and form deep *crevasses* (cracks) that are a major hazard to people who visit Antarctica.

Land regions. The Transantarctic Mountains cross the entire continent of Antarctica. Several ranges make up the Transantarctic chain. Some peaks rise more than 14,000 feet (4,300 meters). The Transantarctic chain has the largest of the ice-free, rocky areas known as *dry valleys.* These valleys were carved by glaciers that once occupied them and later retreated. Snow that falls in dry valleys is swept away by winds. Some of the valleys have lakes.

The Transantarctic Mountains separate Antarctica's two ice sheets and form two regions: (1) East Antarctica and (2) West Antarctica.



East Antarctica covers more than half the continent. The region consists of rocks more than 570 million years old.

Mountains, valleys, and glaciers mark the coast of East Antarctica. The interior of East Antarctica is an ice plateau about 10,000 feet (3,000 meters) above sea level. The continent's thickest ice is in this area. Winds on the plateau blow the snow into ridges, called *sastrugi,* up to

© Guy Mannering, Bruce Coleman Inc.

Ice-free areas called *dry valleys* appear where Antarctica's glaciers have retreated and wind prevents snow from collecting. About 98 percent of the continent lies beneath ice and snow.

6 feet (1.8 meters) high. The South Pole lies on the plateau, at the center of the continent. This pole, also known as the *south geographic pole,* is Earth's southernmost point, where all lines of longitude meet.

East Antarctica also has the *south magnetic pole,* the farthest point on Earth in the direction of magnetic south. It may move as much as 5 to 10 miles (8 to 16 kilometers) in a year. In the early 2000's, it was off the coast of Wilkes Land. For a description of other south poles, see South Pole.

West Antarctica. In this region, much of the rock surface beneath the ice lies below sea level. The region's ice sheet fills deep basinlike areas of land in West Antarctica. If the ice sheet melted, West Antarctica would become a group of islands.

The Antarctic Peninsula is a mountainous, S-shaped finger of land that points out from West Antarctica toward South America. In fact, the peninsula forms a continuation of the Andes Mountain chain of South America. Several islands lie near the peninsula. The South Shetland Islands to the west include Deception Island, an active volcano.

West Antarctica includes several other mountain ranges and volcanoes. Vinson Massif, the highest point in Antarctica at 16,864 feet (5,140 meters), stands in the Ellsworth Mountains near the peninsula. Mount Erebus, Antarctica's most active volcano, lies on Ross Island, which is on the side of West Antarctica that faces New Zealand. The volcano rises 12,448 feet (3,794 meters). Occasionally, it spurts pieces of volcanic rock.

Coastal waters. Two large gulfs cut into Antarctica at opposite ends of the Transantarctic Mountains—the Ross Sea and the Weddell Sea. Smaller bays indent the coastline. Various channels separate offshore islands from the mainland. For example, the Bransfield Strait separates the South Shetland Islands from the mainland.

Broad, flat, floating parts of ice sheets called *ice shelves* fill several of Antarctica's bays and channels. The Ross Ice Shelf, the largest one, measures about 2,300 feet (700 meters) thick at the inner edge and about 660 feet (200 meters) thick at the outermost edge.

In summer, the outer edges of the ice shelves break away and form immense, flat icebergs. This process of iceberg production is called *calving.* These icebergs are larger, smoother, and more evenly shaped than icebergs elsewhere in the world. Scientists have measured Antarctic icebergs with an area as huge as 5,000 square miles (13,000 square kilometers). The icebergs are like giant floating ice cubes. In the future, they may be towed to arid lands and used as a source of fresh water.

Each winter, the surface of the Southern Ocean freezes into a sheet of salty ice called *sea ice.* In summer, this sea ice breaks into pieces called *ice floes.* Winds and waves push the floes against one another, forming thick masses known as *pack ice.* Some pack ice piles up in ridges against the shore. In winter, pack ice extends as far as 1,000 miles (1,600 kilometers) from the coast.

Climate. Antarctica's climate varies from extremely cold, dry conditions on the inland plateau to milder, slightly moister conditions along the coasts. Many people call the plateau a "polar desert." It has only about 2 inches (5 centimeters) of snowfall each year. Annual coastal snowfall averages 24 inches (61 centimeters).

The Antarctic winter lasts from May through September. For several months of the year, the continent is in continual darkness. Summer lasts from November through February. July temperatures range from a low of −94 °F to a high of −40 °F (−70 to −40 °C) inland and from −22 to −5 °F (−30 to −21 °C) on the peninsula's coast. January temperatures range from −31 to 5 °F (−35 to −15 °C) inland and reach 32 °F (0 °C) on the coast. Northern islands may have summer temperatures of up to 50 °F (10 °C).

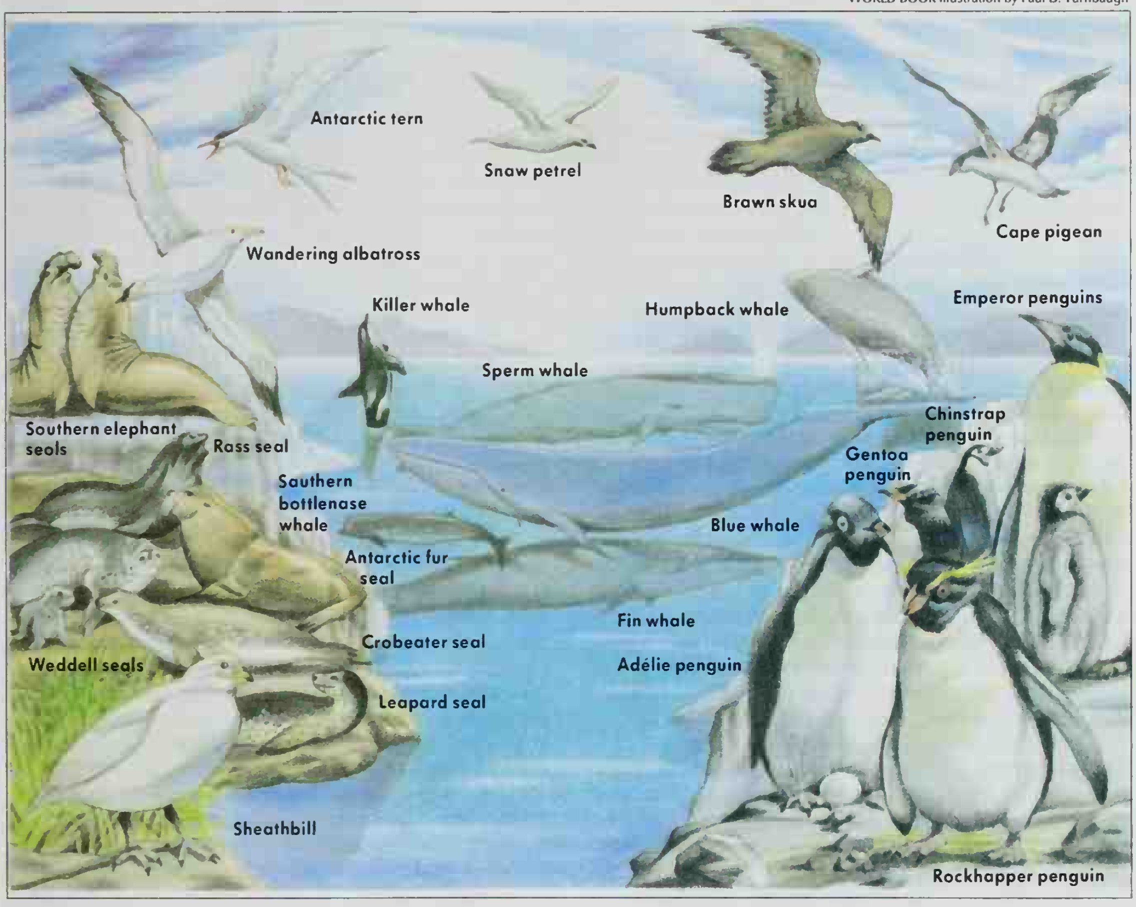
Icy winds make the Antarctic air feel even colder. Winds that sweep downward from the plateau can average 44 miles (70 kilometers) per hour. Gusts often reach the coast at 120 miles (190 kilometers) per hour.

Plants and animals

Plant life. Few plants grow in Antarctica because of the ice-covered land and the harsh climate. Mosses are the most common Antarctic plants. They cling to rocky areas, mostly on the coasts. Only two flowering plants grow in Antarctica. Both live on the northern part of the Antarctic Peninsula. One is a grass that forms dense mats on sunny slopes. The other, an herb, grows in short, cushionlike bunches.

Simpler organisms known as *algae* grow on snow, in lakes, and on ice surrounding the continent. Some algae look like pink or green snow. Other organisms called *lichens* cling to rocks as mosses do. Some lichens survive by bunching together to conserve water. Scientists have discovered rows of black, white, and green lichens growing in tiny cracks in dry valleys. Small plants and algae also drift on the surface of the Southern Ocean.

Animal life. Only a few insects and other tiny animals spend their entire lives on the Antarctic mainland. The continent's largest land animal is a wingless *midge,* a type of fly no more than $\frac{1}{2}$ inch (12 millimeters) long. Most land animals live at the edges of the continent. To avoid freezing to death, some lice, mites, and ticks cling to mosses, the fur of seals, or the feathers of birds.



Unlike the continent, the Southern Ocean has abundant wildlife. The most common animal of the ocean is *krill,* a small, shrimplike creature that feeds on tiny floating organisms. Many other Antarctic animals depend on krill for food, and several countries catch and sell krill as a protein-rich food for people. The *squid*—a soft, boneless sea animal—also is eaten by many Antarctic animals. In addition, about 100 kinds of fish live in the ocean, including Antarctic cod, icefish, and plunderfish.

Several kinds of whales migrate to Antarctica for the summer. Those that feed on krill are blue whales, fin whales, humpback whales, minke whales, right whales, and sei whales. The blue whale is the largest animal that has ever lived. This rare giant grows up to 100 feet (30 meters) long. Antarctic whales that eat fish and squid include killer whales, also called orcas; southern bottlenose whales; southern fourtooth whales; and sperm whales. Killer whales also hunt seals, penguins, and smaller whales.

Various kinds of seals live in Antarctica. They spend most of their lives in the water, where they swim, dive, and catch food. Most of them nest on the coasts. The Antarctic fur seal nests on nearby islands. The largest seal in the world is the southern elephant seal, which feeds on squid. The males may reach a length of 16 feet

Animal life in Antarctica Antarctica's coastal waters have plentiful wildlife, though only tiny animals can survive in the harsh interior. Seals and birds nest on the coast and nearby islands, and whales migrate to the area for the summer. Many of these animals have extra layers of fat to keep warm in the cold, icy climate.

WORLD BOOK illustration by Paul D. Turnbaugh

(5 meters). Weddell seals and Ross seals eat fish and squid. Crabeater seals and Antarctic fur seals eat krill. Leopard seals hunt other seals as well as penguins.

During the 1800's and early 1900's, hunters greatly reduced the number of whales and Antarctic fur seals. Today, international wildlife laws prohibit or restrict the killing of these animals.

Penguins are the animals most often associated with Antarctica. These birds cannot fly, and they waddle awkwardly on land. But they are skillful swimmers. They streak through the ocean, diving for fish and other food. Six kinds of penguins breed on the continent. Playful Adélie penguins, the most common kind, build nests of pebbles on the coasts. The tall, quieter emperor penguin grows to about 4 feet (1.2 meters). After the female emperor penguin lays an egg on ice, the male rests the egg on his feet and warms it with the lower part of his belly. Chinstrap penguins, gentoo penguins, king penguins, and macaroni penguins nest on the Antarctic Peninsula and on islands. Rockhopper penguins nest only on islands north of Antarctica.

More than 40 kinds of flying birds spend the summer in Antarctica. Many types nest on land but spend most of their time diving for food. These birds include albatrosses, prions, and a large group of sea birds known as petrels. Other birds, such as cormorants, gulls, skuas, and terns, return to land more frequently. Some of them steal food from the nests of other birds. Some land birds, such as sheathbills, nest on the peninsula. Others, including pintails and pipits, nest on islands.

Human activities

People wrote about a southern continent centuries before Antarctica was discovered. Ancient Greek philosophers supposed that a land mass at Earth's southern end was needed to balance the weight of the northern lands. During the A.D. 100's, the Greek geographer Ptolemy gave this undiscovered continent the Latin name *Terra Australis Incognita* (unknown southern land). He believed the land was populated and fertile. The name Antarctica later came from two Greek words meaning *opposite the bear.* The Bear is a constellation seen from the northernmost region of Earth.

Early exploration. In 1772, the English navigator James Cook began his search for the southern continent. In January 1773, he crossed the Antarctic Circle, an imaginary line circling Earth at about 66° south latitude. A year later, Cook reached a "farthest south" position of

71° 10′ south latitude. Huge ice blocks prevented him from going farther, however, and he never sighted land.

Nobody knows who first saw the Antarctic continent. Many historians divide the credit among three men who made separate voyages in 1820. In January of that year, Captain Fabian von Bellingshausen of the Russian Imperial Navy reported reaching a point only 20 miles (32 kilometers) from the Antarctic Peninsula. Some historians believe that he saw land but thought it was ice.

That same month, Captain Edward Bransfield of the British Navy journeyed south of the South Shetland Islands and probably saw the Antarctic Peninsula. In November, an American sealer named Nathaniel Brown Palmer reported seeing land during a sealing expedition in the same area. Some geographers later called the peninsula Graham Land in honor of James Graham, who headed the British Navy in Bransfield's time. Others called it Palmer Land. The United States and the members of the Commonwealth of Nations finally agreed to the term Antarctic Peninsula in 1964.

Historians also are unsure of who first set foot on Antarctica. Some believe that an American sealer named John Davis went ashore at Hughes Bay on the tip of the peninsula in 1821. But Davis did not know if he had reached the continent or an island. Whalers made the first known landing on the continent in the late 1800's.

In 1823, a British sealer named James Weddell sailed south in search of hunting waters. He reached about 74° south latitude, farther than earlier voyagers had sailed, and found what is now called the Weddell Sea.

In 1831, an English whaler named John Biscoe became the first to spot land in east Antarctica. Biscoe named it Enderby Land after the whaling company that owned his ship.

In 1837, the king of France sent Lieutenant Jules Dumont d'Urville to claim some southern lands for France. D'Urville's first attempt led him to discover what is now called Joinville Island, off the tip of the Antarctic Peninsula. He began his next Antarctic voyage from Tasmania, an island south of the Australian mainland. In January 1840, he sighted icy cliffs rising along the east Antarctic coastline. Many small penguins dotted the pack ice that blocked his way to the land. D'Urville named both the land and the penguins after his wife, Adélie.

About the same time that d'Urville sighted land, Lieutenant Charles Wilkes of the U.S. Navy headed an expedition to perform scientific research. Wilkes's most important contribution to the study of Antarctica was his coastal exploration. His ship moved from Adélie Coast toward Enderby Land, tracing more than 1,500 miles (2,400 kilometers) of coastline. This distance showed that Antarctica was large enough to be called a continent.

From 1839 to 1843, the British explorer James Clark Ross made several discoveries. Ross was the first person to go beyond the pack ice surrounding Antarctica. He sailed into the gulf that is now called the Ross Sea. Ross also discovered an island with two volcanoes, which he named after his ships, *Erebus* and *Terror*. He found the gulf barricaded by a towering sheet of ice, now known as the Ross Ice Shelf.

In 1895, a Norwegian businessman named Henryk Johan Bull made the first known landing on the Antarctic mainland. He and his whaling crew went ashore at Cape Adare, a point on the Ross Sea facing New Zealand.

The "Heroic Era." The first two decades of the 1900's are often called the "Heroic Era" of Antarctic exploration. During this period, much was learned about the geography and environment of the continent. It was also during this period that explorers first reached the South Pole.

The first inland exploration of Antarctica took place from 1901 to 1904. Robert Falcon Scott of the British Navy led a team of explorers and scientists to the Ross Sea. In November 1902, Scott and two other men headed south across the Ross Ice Shelf. But illness, harsh weather, and lack of food forced them to rejoin the team earlier than planned. Another group moved up a glacier through the Transantarctic Mountains and reached the edge of the icy inland plateau.

Ernest Shackleton, a member of Scott's team, returned to Antarctica in 1907. Part of his expedition headed for the south magnetic pole, the farthest point on Earth in the direction of magnetic south. They reached it in January 1909. The main group headed for the south geographic pole, the meeting point of lines of longitude. Food shortages forced the men to turn back early. But they had arrived within 97 nautical miles (180 kilometers) of the pole, close enough to prove that the pole was on land rather than beneath a frozen sea.

At the opposite end of Earth, Arctic explorers reached the North Pole in 1909. In June 1910, Captain Scott left London, hoping to win for the United Kingdom the honor of reaching the South Pole first. In October, while Scott was in Australia, he received a telegram from the Norwegian explorer Roald Amundsen. The telegram informed Scott that Amundsen, too, was going to Antarctica. Amundsen originally had hoped to be the first North Pole explorer. He switched his goal when he heard that the North Pole had been reached.

The race to the South Pole became one of the most famous events in the history of Antarctica. Amundsen and Scott never met, but both knew that they were racing for the same prize.

Amundsen and his four assistants began crossing the Ross Ice Shelf from the Bay of Whales on Oct. 19, 1911. To reach the inland plateau, they had to carve their own route along an unexplored glacier in the Queen Maud Mountains. The men journeyed on skis and wore light, warm furs. Fifty-two dogs pulled their four sleds carrying food and supplies. Amundsen marked his route and food storage areas with mounds of snow. He shot the weakest dogs for food, when they were no longer needed to pull the sleds.

Scott set out with 15 other men on Nov. 1, 1911, from Cape Evans, Ross Island. This location was about 800 miles (1,300 kilometers) from the pole, about 60 miles (97 kilometers) farther than Amundsen's starting point. However, Scott's expedition reached the plateau by way of the Beardmore Glacier, a known route. Scott used motor-powered sleds to carry some supplies. Ponies and dogs pulled other sleds. But the ponies and motor sleds bogged down in the soft snow. The men had to drag the sleds, and food soon ran low. Scott crossed the plateau accompanied by four men.

Amundsen's group arrived at the South Pole on Dec. 14, 1911. They used special navigating instruments to calculate their position. Amundsen left his tent, a Norwegian flag, and a message for Scott at the pole. The group then headed back to their base, which they

Bettmann Archive

Hulton Getty from Liaison Agency

A dramatic race to the South Pole began in late 1911. British Navy Captain Robert F. Scott, *standing in the group photograph,* and the Norwegian explorer Roald Amundsen, *standing next to the flag of Norway,* each hoped to be the first to arrive at the pole. Amundsen reached the South Pole on December 14, five weeks before Scott. Amundsen's group returned safely. Scott and his men died on the way back, not long after this photograph was taken.

reached on Jan. 25, 1912. By that time, only 11 dogs remained, but all five men were in good health.

Scott's group reached the pole on Jan. 17, 1912, greeted by Amundsen's flag. Cold, hunger, and exhaustion had severely weakened the explorers. They photographed themselves at the pole and began their return. All five men perished on the way. Two of them died after they were injured on the trail. In late March, a long blizzard forced Scott and his two remaining assistants to camp only 11 miles (18 kilometers) away from food and supplies. A search party found their frozen bodies inside the tent eight months later.

Exploration by air provided a new way to study Antarctica. In 1928, the Australian explorer Sir Hubert Wilkins surveyed the Antarctic Peninsula and nearby islands in the first airplane voyage over Antarctic land.

In November 1929, the U.S. Navy officer Richard E. Byrd led the first flight over the South Pole. A Norwegian American pilot, Bernt Balchen, flew Byrd's crew from the Bay of Whales to the pole and back. The flight lasted less than 16 hours. This journey was part of an expedition that Byrd supervised from 1928 to 1930. In a second expedition from 1933 to 1935, Byrd and his assistants traveled by plane and tractor over the Antarctic interior. They studied the ice, Earth's magnetism, cosmic rays, weather, and geology.

In 1935, the U.S. engineer Lincoln Ellsworth and the English-born pilot Herbert Hollick-Kenyon took off from Dundee Island, north of the Antarctic Peninsula, hoping to make the first flight across the continent. Near the Weddell Sea, they discovered what are now called the Ellsworth Mountains. Their plane had to land four times because of storms and a fuel shortage. They finally completed the crossing on foot at the Bay of Whales.

In 1946 and 1947, Byrd commanded the U.S. Navy's Operation Highjump, the largest Antarctic expedition by

Granger Collection

Exploration by air greatly expanded knowledge of Antarctica's geography. In 1929, Richard E. Byrd of the United States Navy first flew over the South Pole. Byrd later led expeditions for the U.S. government in this Fokker trimotor plane.

a single country. Operation Highjump sent 4,700 men, 13 ships, and 23 airplanes and helicopters to Antarctica. The expedition members discovered new land, including 26 islands. They photographed about 1,400 miles (2,300 kilometers) of previously unexplored coastline.

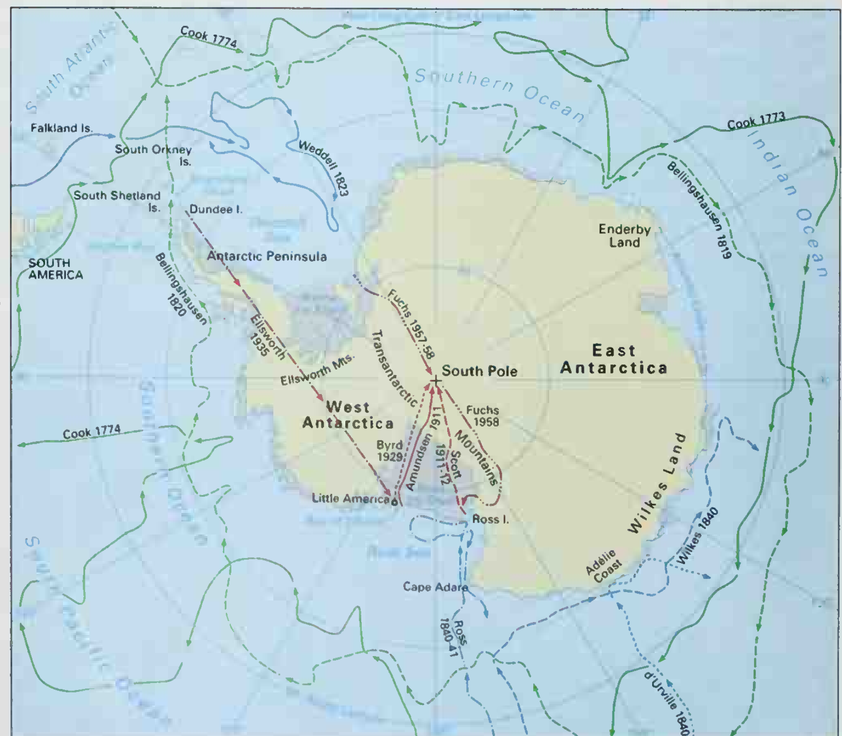
That same year, Captain Finn Ronne led a private U.S. air expedition to West Antarctica. Ronne explored areas of the Weddell Sea that had never been seen. The crew included Ronne's wife, Edith, and Jennie Darlington, the wife of his chief pilot. They were the first women to spend a winter on the continent.

Recent activities in Antarctica have been related mainly to scientific research, tourism, and other peaceful purposes. Scientific knowledge of Antarctica increased rapidly during the International Geophysical Year (IGY), a program in which scientists carried out research and shared their findings. The IGY began on July 1, 1957, and ended on Dec. 31, 1958.

During the IGY, 12 countries established more than 50 scientific stations on Antarctica and nearby islands. These countries were Argentina, Australia, Belgium, Chile, France, Japan, New Zealand, Norway, South Africa, the Soviet Union, the United Kingdom, and the United States. The United States set up a station at the South Pole, plus five coastal stations and one other inland station. The Soviet Union built a station at a point it named the Pole of Inaccessibility. This station, called Vostok, lies in the interior of East Antarctica, far inland from all coasts.

IGY researchers in Antarctica studied such topics as earthquakes, gravity, magnetism, oceans, and solar activity. *Meteorologists* (scientists who study weather) determined air pressure, humidity, temperature, and wind direction and prepared Antarctica's first complete weather charts. *Glaciologists* (scientists who study ice) measured the thickness of the ice. Geologists studied the land formations.

During the IGY, the British geologist Vivian Fuchs headed the first land crossing of the continent. The Commonwealth of Nations organized the expedition, which covered 2,158 miles (3,473 kilometers). Fuchs left on Nov. 24, 1957, from the shore of the Weddell Sea, with dogs and snow tractors. A team led by the New Zealand explorer Sir Edmund Hillary placed food and supplies along the second part of the trail. Hillary met Fuchs at the South Pole in January 1958. Fuchs reached McMurdo Sound in the Ross Sea on March 2, 1958.



Seven of the 12 countries that built Antarctic bases for the IGY claim parts of Antarctica as their national territory. The parts are shaped like pie slices, with the South Pole at the center. The Australian government claims two slices that face Australia. France claims a strip that extends inward from the Adélie Coast. Other claims come from Argentina, Chile, New Zealand, Norway, and the United Kingdom. Many nations, including the United States, do not recognize these claims.

In 1959, officials of the 12 countries signed the Antarctic Treaty. This agreement freezes all current territorial claims in Antarctica and prohibits new claims. It allows people to use Antarctica only for peaceful purposes, such as exploration, scientific research, and tourism. It also requires scientists to share any knowledge that results from their studies. The treaty forbids military forces to enter Antarctica, except those assisting scientific ex-

Antarctica exploration

This map shows the routes of major expeditions in the Antarctic region. The continent was first sighted in 1820. Inland exploration of Antarctica began in the 1900's.

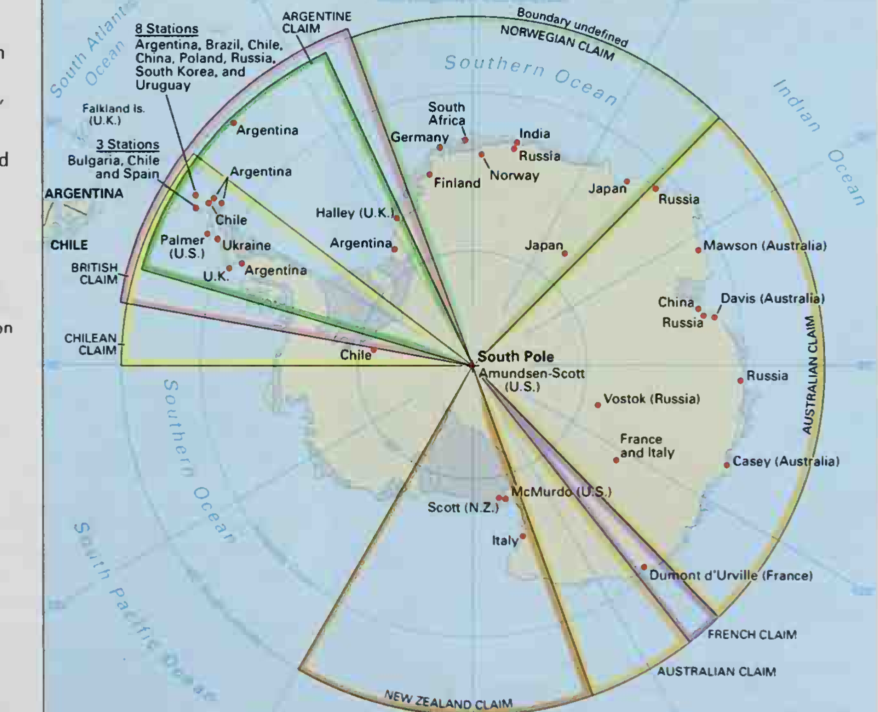
McMurdo Station, a United States research base on Ross Island, has Antarctica's largest community. About 1,000 people live there during the warmer months. A number of other nations—including Argentina, Australia, Chile, New Zealand, Russia, and the United Kingdom—also maintain research stations in Antarctica.

peditions. It also outlaws the use of nuclear weapons and the disposal of radioactive wastes in Antarctica.



Since 1961, when the Antarctic Treaty took effect, a number of other nations have joined the treaty. Many of these nations have set up scientific programs in Antarctica. In 1991, the Antarctic Treaty nations signed the Madrid Protocol. This agreement, which went into effect in 1998, defines Antarctica as a natural reserve devoted to peace and science. The Madrid Protocol prohibits mineral exploitation in Antarctica and establishes strict rules designed to protect the Antarctic environment.

Today, more than 40 year-round scientific stations operate on the continent and nearby islands. The National Science Foundation maintains the three year-round U.S. stations: (1) Amundsen-Scott South Pole Station, (2) McMurdo Station on Ross Island, and (3) Palmer Station on Anvers Island near the Antarctic Peninsula. Other countries that maintain research stations include Argentina, Australia, Brazil, Bulgaria, Chile, China, Finland, France, Germany, India, Italy, Japan, New Zealand, Norway, Poland, Russia, South Africa, South Korea, Spain, Ukraine, the United Kingdom, and Uruguay.

McMurdo Station has Antarctica's largest community. About 1,000 scientists, pilots, and other specialists live there each summer. About 250 people stay for winter. A water plant collects and desalts seawater from McMurdo Sound. Powerful ships called *icebreakers* plow through the ice, arrive with people and supplies, and

Antarctica territorial claims

Seven countries claim areas in Antarctica. This map shows the boundaries of these areas, some of which overlap. The map also pinpoints major Antarctic research stations and indicates the country that operates each station.

leave with waste materials and scientific samples. The station also has runways and a helicopter pad.

Summer activities in Antarctica vary. Geologists collect rock samples from the ice-free dry valleys of the Transantarctic Mountains. Glaciologists measure the speed of ice flow and ice thickness changes. On the coasts and at sea, biologists observe how animals adapt to their environment. Winter restricts scientists to such activities as recording weather data and studying earthquakes and solar radiation.

Some Antarctic studies address global issues. Significant research deals with *ozone,* a form of oxygen. Ozone is most concentrated in a layer that ranges in altitude from about 9 to 18 miles (15 to 30 kilometers). This layer protects all living things from certain harmful rays of the sun. In the mid-1980's, scientists discovered that the ozone layer above Antarctica is becoming less concentrated. Evidence pointed to manufactured compounds called *fluorocarbons* as a major cause of this "ozone hole." See **Ozone hole.**

Researchers also are studying the melting of the ice sheets. This research helps them predict how much sea levels might rise if Earth's average temperature continues to increase.

Antarctica's future. Since the late 1900's, access to Antarctica has become easier, and the number of tourists visiting the continent has been increasing rapidly. Researchers face many challenges in managing the Antarctic environment as the human population grows.

Many scientists believe that research in Antarctica can answer important questions about the past, present, and future of Earth. Future scientific work will likely focus on problems relating to global climate change, including interactions between the northern and southern hemispheres. In addition, studies will likely be done on the biology of huge lakes that have been buried under the ice for millions of years. Wendy Lawson

Michael Parfit

A researcher at the South Pole checks data gathered by a telescope. Antarctica's unpolluted atmosphere enables scientists to obtain an especially clear view of the sky. The dome of the Amundsen-Scott South Pole Station appears in the background.

Anteater is the name of a group of mammals that lack teeth and feed mostly on ants and termites. There are four species of anteaters. The largest and best-known species is the *giant anteater.* It lives in tropical forests and grassy plains from Panama to Argentina. The animal has become rare in some areas as human settlers push into its range.

The giant anteater has a tube-shaped head with a long, slender snout. Its coarse, brittle hair is mostly gray and forms a bushy mass on the tail and sides. A black band of hair bordered by white bands runs from the throat to the middle of the back. Some giant anteaters grow over 6 feet (1.8 meters) in length, including a tail

measuring about 3 feet (0.9 meters) in length.

The giant anteater lives on the ground. It walks with its front feet turned on their sides to protect the claws. When feeding, the animal uses the large second and third claws of its front foot to rip open ant nests. It then flits its tongue, which is about 2 feet (60 centimeters) long, into the nest in rapid in-and-out movements to lick up the ants.

A female giant anteater gives birth to one baby each year. The newborn rides on the mother's back for up to a year.

Two species of anteaters are called *tamanduas,* or *collared anteaters.* Both live in tropical forests and grassy plains. The *northern tamandua* is found from southern Mexico to Peru. The *southern tamandua* lives only in South America. Tamanduas can live both in trees and on the ground. They use their hairless, *prehensile* (grasping) tail for climbing. Tamanduas have short, stiff, tan to brown hair. Some have darker hair around the neck and on other areas of the body. The animals can reach more than 4 feet (1.2 meters) in length.

Peter Weimann, Animals Animals

The giant anteater has a tube-shaped head and snout. The animal licks up ants and termites with its long tongue.

The squirrel-sized *silky anteater* resembles a small tamandua but is covered with soft, golden-yellow or gray fur. This anteater can grow about 20 inches (50 centimeters) long. It lives in trees in the tropical forests of southern Mexico, Central America, and South America.

Aardvarks, pangolins, and echidnas are also sometimes called *anteaters.* These animals feed on termites and ants and have other characteristics in common with anteaters, but they belong to different *orders* (scientific groups).

Scientific classification. Anteaters belong to the family Myrmecophagidae in the order Xenarthra. The giant anteater is *Myrmecophaga tridactyla.* The northern tamandua is *Tamandua mexicana,* the southern tamandua is *T. tetradactyla,* and the silky anteater is *Cyclopes didactylus.* Duane A. Schlitter

Antecedent, *AN tuh SEE duhnt,* is a word or group of words to which a pronoun refers in a sentence. An antecedent may come before or after the pronoun. In the sentence *Venice is famous for its canals,* the antecedent *Venice* comes before the pronoun *its.* In the sentence *At her best, Jill was unbeatable,* the antecedent *Jill* comes after the pronoun *her.*

Personal pronouns, such as *I, you, he, she,* and *it,* must agree with their antecedents in *gender, number,* and *person.* The pronoun's *case* is determined by its use in the sentence. For example, the sentence *The children, after seeing the movie, were asked what they remembered about it* contains two personal pronouns, *they* and *it.* The pronoun *they* agrees with its antecedent *children* in gender (common), number (plural), and person (third). *They* is the subjective case because the pronoun is the subject of the verb *remembered. It* agrees with its antecedent *movie* because both are neuter in gender, singular in number, and in the third person. But *it* is the object of *about* and so is in the objective case.

Special problems in agreement arise in cases where the antecedent is an indefinite pronoun, such as *all, each, none,* and *some.* Some indefinite pronouns, such as *everyone* and *somebody,* have a singular form but are plural in meaning. In formal usage, singular pronouns are used: *Everyone did his or her share.* Informal usage, especially in speaking, favors the plural: *Everyone did* their *share.*

The pronouns *all, any, each, none,* and *some* can be either singular or plural, depending on their use. For example, Some *of the crop is now at* its *best* (singular); Some *of the apples are now at* their *best* (plural).

Agreement problems may develop when the antecedent is a collective noun, such as *crew* or *jury.* The use of singular or plural pronouns with collective nouns depends on the intention of the speaker or writer. The use of the singular emphasizes the entire unit: *The* jury *was unanimous in* its *decision.* The use of the plural stresses the parts of the unit: *The judge told the* jury they *were dismissed.*

Confusion can result from the careless use of relative pronouns—*that, what, which,* or *who.* In the sentence *The club adopted a new constitution, which we thought was a good idea,* the relative pronoun could refer either to *adopted* or to *constitution.* For clarity, the statement should be divided into two sentences: *The club adopted a new constitution. We thought the adoption was a good idea.* Patricia A. Moody

Antelope is the name of a large group of animals that have hoofs and hollow horns. They belong to the same animal family as goats and oxen. But antelope more closely resemble deer, because most of them are slender and graceful. Antelope, like cattle, are *ruminants* (see **Ruminant**).

Antelope keep their horns as long as they live. Among many kinds of antelope, both the males and the females have horns. The horns of the males usually grow larger. Some antelope have short, straight horns. The horns of others are long and curved, sometimes in a spiral twist. Some antelope horns are smooth, while others have ring-shaped ridges along their length. Antelope horns form around a single bony core. The horns are never forked like tree branches, as are deer antlers.

Most antelope live in Africa, but a few *species* (kinds) are found in Asia. The North American *pronghorn* is not a true antelope, though it resembles antelope (see **Pronghorn**). Some antelope, such as the *duiker* and the *bongo,* live in forests. Others live on mountainsides. A

Mark Boulton, NAS

The eland can jump an obstacle 6 feet (1.8 meters) high from a standing start. This antelope lives in small or large herds.

C. G. Hampson, APF

The dik-dik lives alone or in small family groups in dense woodland areas. If startled, dik-diks quickly scurry to safety.

few, such as the *sitatunga* and the *lechwe* of central Africa, live in marshes. But more kinds and greater numbers of antelope live on the dry or grassy plains of eastern and southern Africa than anywhere else.

Some Africans hunt antelope for food. Game ranches also raise many kinds of antelope for meat. Antelope make good meat animals in tropical areas, because herds of several species feed on more kinds of tropical plants than do cattle or sheep. In addition, antelope have better resistance to tropical diseases.

Habits and appearance. Most antelope are timid and run away from their enemies. The *gazelle* and the *blackbuck* are among the fastest runners in the world. A few antelope defend themselves when they must. They are the *gnu,* the *roan* antelope, and the *sable* antelope, all found in Africa. Sometimes other animals warn antelope of danger.

Among many antelope, the male defends a *territory* (area of land) during the breeding season so that other males may not enter it. The females visit the territories and mate with the males of their choice.

Antelope vary in size. Some, such as the *dik-dik* and the *steenbok* are not much larger than jack rabbits. Others, notably the *eland,* grow about the size of an ox.

A smooth coat of hair covers the skin of most antelope, except a few such as the shaggy-haired *waterbuck.* This coat may appear in various shades and patterns. Brown and gray are the most common colors. Antelope have long been hunted, both for the thrill of the sport and for their flesh and skins. Certain herds of African antelope which contained thousands of animals have been completely destroyed by hunters. Many of the most handsome kinds of antelope, such as the *bontebok,* the *giant sable,* and the *white oryx,* have become scarce. Some are found only on private estates. Overhunting has wiped out others, such as the *bluebuck.*

Kinds of antelope. Separate articles in *World Book* describe several kinds of antelope. See the list of *Related articles* at the end of this article. There are many other kinds, all in the Eastern Hemisphere. One of these is the *four-horned* antelope. The males of this Indian antelope have two pairs of horns instead of the usual single pair. Several kinds of *harnessed* antelope live in central and southern Africa. The stripes on their bodies make them appear to be wearing a harness. Only the males of this kind have horns.

The *klipspringer,* a small antelope that resembles the European chamois, lives in rocky places from southern

Antenna, also called *aerial,* is a device that transmits and receives radio, television, and radar signals. These signals, known as *electromagnetic signals,* take the form of waves of energy. They travel through space at the speed of light. Electromagnetic waves differ in their *frequency* (rate of vibration). Radio, television, and radar stations transmit at different frequencies so their signals do not interfere with one another. The two kinds of radio transmissions are *amplitude modulation* (AM) and *frequency modulation* (FM). In general, AM signals have lower frequencies than FM signals. Television programs are transmitted by electromagnetic waves that are similar in frequency to FM signals.

The size, shape, and complexity of an antenna system depend on the range of frequencies being transmitted or received. Antenna systems may also be designed with different *directional properties* so that they need not send out or pick up signals equally in all directions.

Transmitting antennas usually consist of one or more towers. A group of towers can direct stronger signals in certain directions. AM transmitting antennas stand from 250 to 500 feet (75 to 150 meters) tall. FM and television antennas must be placed as high as possible to increase their range. This is because FM signals and TV signals spread horizontally and cannot be received beyond the horizon as seen from the transmitting antenna. AM signals, on the other hand, bounce off the atmosphere and can reach beyond the curve of the earth. In general, a TV antenna has a range in miles equal to the square root of one-and-a-half times its height in feet. Thus, an antenna 600 feet (180 meters) high would have

Kinds of receiving antennas

WORLD BOOK diagrams by Arthur Grebetz

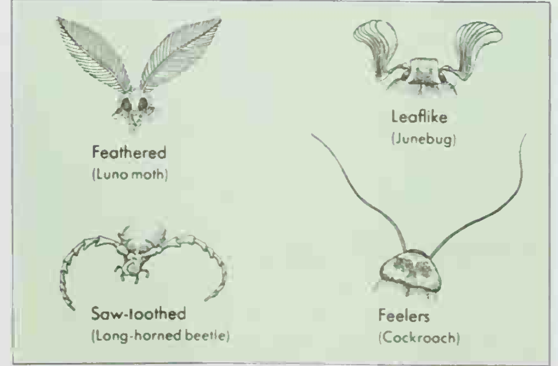
Several types of antennas may be used to receive radio or television signals. The illustrations above show four of the most common types of receiving antennas.

a range of approximately 30 miles (48 kilometers).

Receiving antennas for AM radio consist of a wire coil inside the radio set. Such *loop antennas* receive a stronger signal when the coil points toward the transmitting antenna. Receiving antennas for FM signals are similar to antennas used to receive television signals.

Many kinds of antennas can be used for TV reception. The antenna's size generally depends on the frequency of the signals. For example, an adjustable indoor antenna, commonly called *rabbit ears,* should be lengthened to receive lower frequencies, such as channel 2, and shortened to receive higher frequencies, such as channel 13.

The most widely used TV antenna is a *dipole,* which consists of a straight metal rod or wire that is split in the center. A *folded dipole* consists of two dipoles that are connected at the ends. Only one dipole is split. Dipoles range in length from about 6 to 100 inches (15 to 250 centimeters). *Multiple element antennas* have several dipoles of different lengths to improve the reception of various frequencies. Metal rods called *directors* and *reflectors* strengthen the signals.



Dish antennas, also known as *parabolic* (bowl-shaped) *reflectors,* may be used to relay electromagnetic signals to and from artificial satellites. The use of satellites has made it possible to transmit television programs great distances. An earth-based dish beams signals into outer space. A satellite receives the signals, *amplifies* (strengthens) them, and transmits them back to the earth. Earth-based dish antennas receive and amplify the weak signals. Early receiving dishes had a diameter of more than 10 feet (3 meters). Today, a dish antenna may measure only about 3 feet (0.9 meter) across.

Radar antennas emit and collect radar waves. Early radar systems needed a large dish antenna to focus the signals. Today, police systems, which detect speeding vehicles, use antennas small enough to be put on police cars. See Radar (The antenna). Thomas T. Liao

Antennae, *an TEHN ee,* are long, delicate sensory organs on the heads of almost all insects and most other arthropods (see Arthropod). Insects, centipedes, and millipedes have a single pair of antennae. Crustaceans, such as lobsters and crabs, have two pairs of antennae. Spiders and their relatives have none.

The antennae contain many nerves and may be sensitive to heat, vibrations, water vapor, and certain chemicals and gases. Fine hairs that cover the antennae serve as touch receptors. Tiny pits in the antennae of some insects make them useful in smelling. A Junebug has nearly 80,000 such smelling pits. The antennae of male mosquitoes have hairs that are sensitive to sound. These mosquitoes can use their antennae to detect the sound of female mosquitoes as much as $\frac{1}{4}$ mile (0.4 kilometer) away. E. W. Cupp

Anthem. See National anthem; Hymn.

Anther. See Flower (The stamens; diagram: Parts of a flower).

Anthony, Susan Brownell (1820-1906), was a reformer and one of the first leaders of the campaign for women's rights. She helped organize the woman suffrage movement, which worked to get women the right to vote.

Anthony was born in Adams, Mass. Her family were Quakers, who believed in the equality of men and women. Anthony's family supported major reforms, such as antislavery and *temperance,* the campaign to abolish alcoholic beverages.

From 1839 to 1849, Anthony taught school. She then joined the temperance movement. But most temperance groups consisted of men who did not allow women to help the movement. In 1852, she attended a temperance rally in Albany, N.Y., but was not allowed to speak because she was a woman. Soon after, she formed the Woman's State Temperance Society of New York.

Through her temperance work, Anthony became increasingly aware that women did not have the same rights as men. In 1851, she met Elizabeth Cady Stanton, a leader of the women's rights movement. The two women became close friends and co-workers. Soon, Anthony devoted herself completely to women's rights and became a leader of the movement. She supported dress reform and, for a time, wore bloomers, which became a symbol of the women's rights movement. She also worked in support of equal educational opportunities and property rights for women.

Before and during the Civil War (1861-1865), Anthony and Stanton supported abolitionism. After the war, however, they broke away from those who had been involved in the abolitionist movement. Many of these people showed little interest in woman suffrage and supported the 15th Amendment to the Constitution of the United States. This amendment gave the vote to black men, but not to women. In 1869, Anthony and Stanton formed the National Woman Suffrage Association and worked for a woman suffrage amendment to the Constitution.

From 1868 to 1870, Anthony published a weekly journal, *The Revolution,* which demanded equal rights for women. In 1872, she voted in the presidential election and was ar-

Brown Bros
Susan B. Anthony

rested and fined $100 for voting illegally. Anthony never paid the fine, but no further action was taken against her. From 1881 to 1886, Anthony and Stanton coedited three volumes of a book called *History of Woman Suffrage.* Anthony completed a fourth volume of the book in 1902. In 1904, she established the International Woman Suffrage Alliance with Carrie Chapman Catt, another leader of the suffrage movement.

In 1890, the National Woman Suffrage Association and the American Woman Suffrage Association united to form the National American Woman Suffrage Association. Anthony served as the group's president from 1892 until 1900. She died on March 13, 1906, 14 years before the 19th Amendment to the Constitution became law and gave women the right to vote. In 1979 and 1980, the United States minted for circulation $1 coins bearing Anthony's picture. She was the first woman to be pictured on a U.S. coin in general circulation. June Sochen

Anthony of Padua, *PAJ oo uh,* **Saint** (1195-1231), was a Christian religious leader and a popular preacher of his time. Many miracles have been attributed to Anthony, both during his lifetime and after his death. Anthony's body lies in a church built in his honor in Padua, Italy. The church has become a shrine, attracting thousands of pilgrims seeking the saint's aid.

Anthony was born in Lisbon, Portugal, probably on Aug. 15, 1195. His original name was Ferdinand. He entered the Augustinian canons, a religious order, about 1210 and joined the Franciscan order in 1220, taking the name Anthony. He traveled to Morocco to convert the Muslims, but became ill and returned to Europe. Anthony's ship landed in Sicily, and he settled in Italy. After leading a solitary life for a short time, Anthony began to preach. He amazed his listeners with his skill as a speaker and his knowledge of the Bible. Anthony delivered sermons before huge crowds in Florence and Padua. He showed deep concern for the common people, who loved him as their protector. He died on June 13, 1231, and his feast day is June 13. Marilyn J. Harran

Anthony of Thebes, Saint (250?-356), was the founder of Christian monasticism. Anthony spent much of his life as a hermit in the Egyptian desert. He established religious communities of hermits that became models for monastic life.

Anthony was born in a village in Egypt. At about age 20, he gave away his belongings and began living a hermit's life of *asceticism* (self-denial). He studied with another hermit and later lived in empty tombs near his home for about 15 years. There he practiced spiritual discipline alone. He later lived in an abandoned desert fort for 20 years, where he fasted, prayed, and worked. During that time, his reputation as a holy man grew, and eventually he left his solitude to teach others the ascetic life. He spent his last years in solitude on a mountain.

Saint Athanasius wrote the influential *Life of Anthony* in 357. It described Anthony's piety and his legendary battles against temptations sent by the Devil. Anthony's feast day is January 17. Marilyn J. Harran

Anthracite. See Coal (How coal was formed; Where coal is found; map; The uses of coal).

Anthrax is a serious infectious disease that chiefly affects animals but can also occur in people. It is caused by the bacterium *Bacillus anthracis.* Anthrax usually affects plant-eating animals infected by eating anthrax *spores* (inactive bacteria) from the soil. Anthrax spores can survive harsh conditions and occur in soil throughout the world, including the United States. People can get anthrax through contact with infected animals or contaminated animal products. But, naturally occurring anthrax is rare in human beings today.

In people, anthrax infection can occur in three main forms: *inhalational,* caused by breathing in spores; *cutaneous,* caused by spores infecting skin sores; and *gastrointestinal,* caused by swallowing spores. Inhalational anthrax causes a severe illness that begins in the chest and rapidly spreads through the body. Cutaneous anthrax, the most common form, can cause a severe skin infection. Gastrointestinal anthrax results from eating undercooked, contaminated meat. Symptoms include fever, vomiting, abdominal pain, and bloody diarrhea. Anthrax can be cured with antibiotics if patients receive treatment early. However, inhalational and gastrointestinal anthrax are often fatal if not rapidly treated.

Some nations and international terrorist groups are known to have developed or suspected of having developed anthrax as a biological weapon. In 1979, the accidental release of anthrax spores from a military facility in the Soviet Union caused 68 deaths. In the 1990's, Russia—which had been the largest part of the Soviet Union—announced it had ended all biological weapons programs. Many nations are now working to end the development and use of biological weapons, including anthrax.

In 2001, anthrax spores were used as a weapon when they were sent through the United States mail to several business and government offices. As a result, a number of office buildings and post office facilities were contaminated. Some people became ill with inhalational anthrax, and several of them died. Others contracted cutaneous anthrax. Investigators began trying to determine who was responsible for the attack. Thomas V. Inglesby

Anthropoid. See Primate.

Anthropology is the scientific study of humanity and of human culture. It is unique among the social sciences in that it focuses on all societies and all aspects of human physical, social, and cultural life. Anthropologists investigate *culture,* the strategies for living that people learn and share as members of social groups.

Anthropologists also examine the characteristics that human beings share as members of a single species and the diverse ways that people live in different environments. They also analyze the products of social groups—both material objects and less material creations, such as beliefs and values.

Like other social scientists, anthropologists look sys-

John W. Burton, the contributor of this article, is Professor of Anthropology at Connecticut College.

tematically for general patterns in human behavior. They develop theories and use scientific methods to test them. Anthropologists study and try to understand cultures different from their own, and describe them to members of their own society.

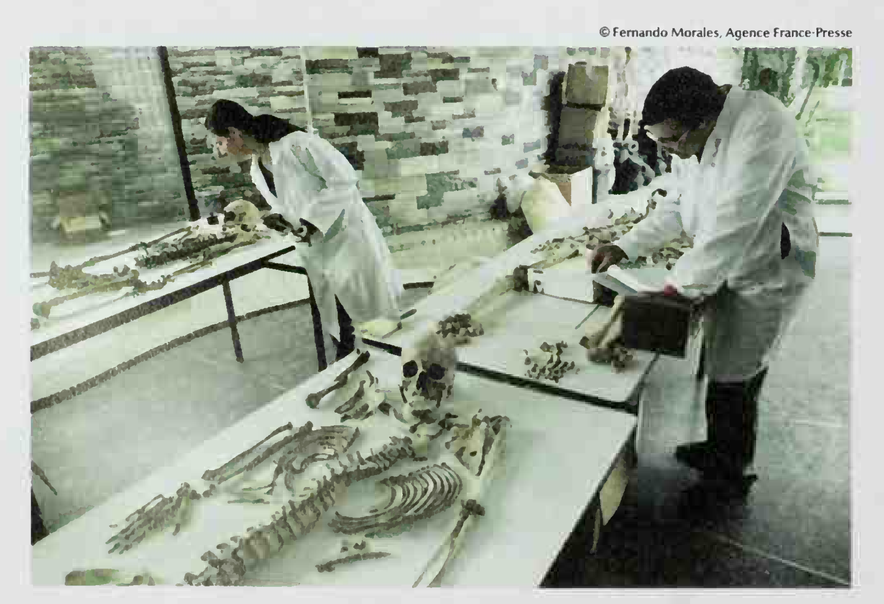
Anthropologists are interested in understanding all human societies. Their research is *cross-cultural,* meaning that they focus on those aspects of human experience found in all cultures. But anthropology is also *comparative,* meaning that anthropologists are interested in how the particular features of cultures are alike and how they are different. For example, marriage in Western societies is a union between one man and one woman. But marriages are different in other parts of the world. In many African and Islamic societies, a man may be married to more than one woman at a time. Among the Nyinba people and other groups of Nepal, however, a woman typically marries several men who are brothers.

Another important feature of anthropology is its emphasis on an insider's view of a society. Anthropologists try to determine how people who share a culture view their world. Anthropology can make major contributions to international harmony because it helps provide an understanding of various cultures.

Because different cultures and societies have different habits and customs, anthropologists use the term *cultural relativism* to describe and understand different cultures. This concept suggests that one culture is not better or worse than any other—it is merely different.

The concept of cultural relativism in anthropology is closely related to the concept of *ethnocentrism.* Ethnocentrism refers to the idea that one's own culture is inherently superior to a different culture. Such an assertion is a form of racism, and anthropologists strive to show that racist claims have no scientific proof. They are instead a form of ethnocentrism. See Ethnocentrism.

Branches of anthropology



The chief branches of anthropology include *physical anthropology, archaeology, linguistic anthropology,* and *social anthropology,* also called *cultural anthropology.* These branches often overlap. For example, archaeologists and cultural anthropologists study many of the same cultural features. But archaeologists concentrate on past civilizations, and cultural anthropologists work mainly on present ones.

Physical anthropology, also called *biological anthropology* or *bioanthropology,* is the study of human physical characteristics. Physical anthropologists, called *paleoanthropologists,* search for fossil remains from prehistoric times to trace the development of human physical characteristics. They also seek remains, such as stone tools and evidence of fires, to analyze the links among physical traits and cultural development.

Some physical anthropologists study primates—the animals that are most closely related to human beings, including chimpanzees and other apes. By observing these animals, the scientists try to understand what our prehuman ancestors were like and how human beings have changed through millions of years. Advances in the study of human and animal genes help scientists discover how closely different species and different groups of people are related to one another.

Other physical anthropologists study physical differences among human beings, including blood types, skin colors, and hereditary diseases. They also analyze the effect of nutrition and environmental factors, such as altitude and climate, on human growth and development. For example, studies have shown that people who spend their entire lives in the high-altitude Andes Mountains have larger hearts and lungs than people who live at lower altitudes. The enlarged organs are an adaptation to the lower oxygen concentration of high-altitude environments.

Archaeology is the study of objects left by earlier peoples, including artwork, buildings, clothing, pottery, and tools. Archaeologists trace the development of cultures by studying the things those people made and used. Such objects help them determine what early social life may have been like. For example, the size of

Physical anthropologists examine skeletal remains in a Guatemalan laboratory to identify victims of a civil war. Physical anthropologists are often called to help law enforcement agencies identify human remains in cases of crime, war, or natural disaster.

houses and the number of cooking hearths may show how many people lived together in a household. Differences in the number and value of objects put in graves may indicate differences in social class. Animal bones and plant pollen show whether people raised animals or hunted them and whether they grew crops or gathered wild plants for food. See **Archaeology**.

Linguistic anthropology analyzes the ways that language is used by people of different societies. Anthropological linguists try to find connections between people's language and other aspects of their culture. In the Indonesian language, for example, many statements include a reference to the social status of the person addressed. Houses and other objects have various names, depending on the rank of the listener. This use of language reflects the great importance of social class in Indonesian culture.

Other topics of study for anthropological linguists include formal and informal speech, forms of address, insults, and jokes. These experts also analyze the structure of unwritten languages. Some anthropological linguists study how words and their definitions and classifications reflect people's views of their environment and society. The Nuer, a herding people of eastern Africa, have many words for the colors and markings of cattle. Their vocabulary shows the importance of livestock in their way of life.

The ways that different cultures classify such things as animals, plants, and relatives show how they view the world. The English language uses the same word—*uncle*—for a mother's brother, a father's brother, and the husband of either parent's sister. But some languages have a word for each of these relatives. Such words suggest differences in the roles and behavior expected of such relatives.

Cultural anthropology is the study of human culture. Cultural anthropologists study the artwork, houses, tools, and other material products of a culture. They also study a culture's nonmaterial creations, including its music, religious beliefs, symbols, and values.

Some anthropologists specialize in various fields of cultural anthropology. *Ecological anthropologists* investigate the way a society fits into its environment and how the environment affects the society's culture. *Psychological anthropologists* study how individual personalities are shaped by different cultures and how children learn to share in their culture. *Medical anthropology* examines the ways in which different people and cultures experience, describe, and understand illness.

Social anthropology deals with social relationships in groups. Such relationships include marriage, family life, authority, and conflict. Social anthropologists devote much research into how social life is organized in different societies. A researcher might study a community to see how people are divided into groups within it and to learn about relationships among these groups.

Many studies examine such human characteristics as age, sex, and kinship, which are universal but have different functions in various societies. In some communities, these characteristics determine what society expects from an individual. In others, such characteristics as education, income, and occupation help define how people are expected to behave.

Early social anthropologists often studied an entire community, including all aspects of its life. Today, however, these scientists practice several specialties. For example, *economic anthropologists* concentrate on how food and other goods are produced and distributed. *Political anthropologists* analyze how decisions are made and how conflicts are resolved within communities.

Social and cultural anthropologists do not study only non-Western societies. Many anthropologists also work in Europe and North America. They point out that no human society is isolated from other societies.

How anthropologists work

The primary method used by anthropologists to collect and understand information on human cultures is known as *fieldwork*. The first anthropological researchers worked in isolated societies about which little was known. They attempted to describe the culture of the people they studied as completely as possible. The research and description of a culture, called *ethnography,* describes details on the people's values, daily life, material culture, and social relationships. See **Ethnography.**

To study societies, anthropologists developed a method called *participant observation*. The researcher, called a *participant-observer,* learned about a people by living among them and taking part in their daily lives. Although it is impossible to record information on every aspect of a culture during fieldwork, anthropologists try to learn all that they can from local people. Today, participant observation is still the most characteristic technique of anthropology, but anthropologists use many other methods as well.

Like all scientists, anthropologists begin their research by asking questions and formulating possible answers called *hypotheses*. Then they collect evidence with which to evaluate the hypotheses.

Entering the community. Most anthropologists have interests in a particular geographic area of the world but also look to answer specific questions about human culture. For example, in the 1930's, the British anthropologist E. E. Evans-Pritchard lived among the Nuer in Sudan. At the time, the Nuer did not have chiefs or kings or any kind of government. Evans-Pritchard stud-

WORLD BOOK photo

A cultural anthropologist, *left,* conducts fieldwork in a rural village in Uzbekistan. He is listening to a grandmother talk about life in the village and how village life has changed over time.

ied the problem of how a society without a political system could hold together and work.

Before anthropologists begin their fieldwork, they read about and try to gain knowledge about the region where they will conduct their research. If possible, they learn the language that is spoken there before they arrive at a fieldwork site.

After arriving at a field site, the anthropologist must find a place to live and try to blend into the local society. Local people often take in and house such researchers and befriend them. After time, the scientist begins to learn the language, values, sentiments, and other *norms* (standards) of the culture. Fieldwork usually takes at least one year. It is important for an anthropologist to see how seasonal changes affect the way people live and what they do to gain their livelihood.

At first, the researcher gathers information mainly through observation and conversations with members of the community. Many researchers conduct a community census to collect basic information. Most field workers take notes every day and type them up at night. Some anthropologists revisit the same community many times over many years, while others carry out fieldwork in a number of different societies.

Developing hypotheses. An anthropologist must decide what information he or she wishes to gather about the community. Then the researcher asks questions and forms hypotheses to answer them. Many new questions will arise from what the scientist has already learned about the community.

Collecting evidence. After developing specific hypotheses, the anthropologist gathers information to test them. The researcher may conduct a survey by distributing questionnaires to everyone in the community or to a selected group of individuals. He or she may take inventories of household possessions or obtain life histories from a number of people. An anthropologist may record interviews, music, or special events, and make motion pictures or photographs of various activities.

Drawing conclusions. The researcher must organize all the information that has been collected so it can be used easily and efficiently. The anthropologist, like other scientists, may use a computer to analyze large amounts of information. Finally, the researcher evaluates the hypotheses that have been formulated and writes up his or her conclusions for scientific journals or in books.

History

Early anthropological thought. As long as human beings have been aware of other human beings, they have compared one society to another. In the past, myth and imagination often inspired the observation of other peoples. Some European travelers in the 1600's and 1700's reported that they had seen human beings in different parts of the world with one eye, with four legs, or with three heads. Many people were not even aware that there was a single species of human being.

Anthropology did not become a separate area of study until the mid-1800's. In 1859, the British naturalist Charles R. Darwin presented some key ideas in *The Origin of Species,* one of the most influential science books ever written. In it, Darwin explained his theory of *natural selection,* the process in nature by which the people, other animals, and plants best adapted to their environment tend to leave the most offspring. The theory of natural selection helped explain the workings of *evolution,* the process by which all living things developed from a few simple forms of life through a series of changes.

Early anthropologists came to the conclusion that all members of the human species shared a common past. They tried to determine how different societies were related and how they had evolved. They viewed the history of human culture as a process of evolution from lower to higher forms. For example, the American scholar Henry Lewis Morgan imagined that all human societies evolved through a fixed series of stages, from savagery, to barbarism, to civilization.

According to Morgan and other early anthropologists, this process climaxed with the cultures of Europe and North America. So-called primitive peoples, whose technology was less advanced than that of the West, supposedly represented earlier stages of development.

Development of field research. By the late 1800's, many anthropologists began to criticize the evolutionary theories of Morgan and others. To support their criticism, such anthropologists as Adolf Bastian of Germany, Franz Boas of the United States, and William H. R. Rivers of the United Kingdom organized expeditions to observe the cultures of other societies firsthand.

In 1899, at Columbia University in New York City, Boas founded the first major department for the teaching of anthropology. His students included Ruth F. Benedict, Alfred L. Kroeber, Robert H. Lowie, and Margaret Mead, all of whom became famous anthropologists. Boas trained them to conduct intensive eyewitness studies of individual cultures. The resulting field studies highlighted many differences among societies.

The early 1900's. During the 1920's, the Polish-born British anthropologist Bronislaw Malinowski developed an approach called *functionalism.* Functionalism stressed the ways that different cultural traits function to

Margaret Mead

Margaret Mead, an American anthropologist, *left,* lived among the Samoans in 1925 and 1926 to observe their ways of life. Her research resulted in the book *Coming of Age in Samoa* (1928).

satisfy basic human needs, both biological and psychological. Malinowski's students included the prominent British anthropologists E. E. Evans-Pritchard, Raymond Firth, Max Gluckman, and Isaac Schapera, and an American, Hortense Powdermaker.

By the late 1920's, anthropologists from Europe and North America had carried out fieldwork throughout the world. The results of their research changed the nature of anthropology and also revolutionized the Western view of "primitive" people. The new method of participant observation questioned and dramatically changed the idea that such people were less highly evolved than European or American society.

Anthropologists realized that every society had its own history, and that these histories did not conform to the evolutionary schemes of Morgan and others. Fieldwork showed that human cultures grew, changed, and adapted through human invention and creativity, and through contact with different cultures. Many anthropologists recognized that peoples throughout the world had been dramatically affected by contact with Europeans over the past 300 years. The scientists felt that information about various groups should be gathered before the cultures of those groups were further transformed by contact with the West.

The middle and late 1900's. Rapid and extensive changes in many societies during the middle and late 1900's stimulated a shift in anthropological thought. Instead of studying a society at a specific point in time, anthropologists began to study the culture at intervals. They wanted to learn how the society had changed and to analyze the process of change itself. For example, Clifford J. Geertz of the United States studied economic development in Indonesia. Abner Cohen of the United Kingdom investigated the changing role of religion among the Hausa cattle traders of Africa.

Nearly all early anthropologists were Europeans or North Americans who studied societies in Africa or other distant areas. During the mid-1900's, African and Asian anthropologists began to study societies in the West that formerly had sent researchers to their countries. The Nigerian anthropologist John Ogbu investigated a suburban school in California. Another Nigerian anthropologist, E. U. Essien-Udom, studied the Nation of Islam, also known as the Black Muslims, a religious group in the United States.

Modern anthropology. Early anthropologists mainly studied small communities in technologically simple societies. But modern anthropologists work in a wide range of settings. An anthropologist may study how a small community responds to contact with modern society, as George Foster of the United States did in the Mexican village of Tzintzuntzan.

Anthropologists continue to find new problems and topics to study as societies continue to change throughout the world. Today, many anthropologists are interested in issues related to globalization and a growing population of people termed *transnationals.* These people are born in one part of the world but later migrate to a different region and live in a different culture. Such people carry with them elements of two cultures.

Careers in anthropology

Most careers in anthropology require either a master's degree or a doctoral degree. Many anthropologists teach and carry out research in colleges and universities. Some collect and supervise the display of items for museums.

An increasing number of anthropologists enter the growing field of *applied anthropology,* the use of anthropological research to achieve a practical goal. They may work for government-sponsored development projects or relief agencies helping to assist refugee populations throughout the world. Applied anthropologists also work in advertising and other corporate jobs, where they can apply their knowledge about social systems to specific problems. John W. Burton

Anthurium, *an THUR ee um,* is the name of a large *genus* (group) of flowering plants native to tropical regions in North and South America. There are about 1,000 species of anthuriums. They grow wild chiefly in rain forests. They are also cultivated in greenhouses and gardens.

Many wild anthuriums wrap around tree trunks and branches, though some grow along the ground. Most anthuriums have large evergreen leaves shaped like hearts. In some species, the leaves are lobed or separated into fingerlike leaflets. Anthuriums bear small flowers tightly packed on a cylindrical, fleshy stalk called a *spadix.* The spadix rises from a shiny, leaflike *spathe,* which is often brightly colored.

A commonly cultivated anthurium is the *pink flamingo,* also called the *flamingo lily.* This plant has a bright pink spathe that lasts several weeks. Gardeners also grow anthuriums for their attractive leaves. The leaf veins of some species are outlined in pale green to silvery white against a dark green or purple background.

David H. Wagner

Scientific classification. Anthuriums belong to the arum family, Araceae. The scientific name for the pink flamingo is *Anthurium andraeanum.*

Antibiotic, *AN tee by AHT ihk* or *AN tih by AHT ihk,* is a substance produced by certain bacteria or fungi that kills other cells or interferes with their growth. In nature, these substances help some microbes survive by limiting the multiplication of other microbes that share the same environment. Antibiotics that attack *pathogenic* (disease-causing) microbes without severely harming normal body cells are useful as drugs.

Antibiotics are especially useful for treating infections caused by bacteria. Antibiotics came into widespread use during the 1940's. At that time, they were often called "wonder drugs" because they cured many bacterial diseases that were once fatal. The number of deaths caused by meningitis, pneumonia, tuberculosis, and scarlet fever declined drastically after antibiotics became available. Today, physicians prescribe antibiotics to treat many diseases caused by bacteria.

In addition, some antibiotics are effective against infections caused by fungi and protozoa, and a few are useful in treating cancer. Antibiotics are also used to treat infectious diseases in animals. Farmers sometimes add small amounts of antibiotics to livestock feed. The antibiotics support the animals' growth for reasons that are not entirely understood.

Antibiotics are not effective against colds, influenza, or other viral diseases. In addition, the effectiveness of antibiotics is limited because both pathogenic microbes and cancer cells can become resistant to them.

Kinds of antibiotics

Antibiotics are *selectively toxic*—that is, they damage some types of cells without harming others. Medically useful antibiotics attack infectious microbes or cancer cells without excessively hurting human cells. Antibiotics fight different types of illnesses in a variety of ways.

Antibacterial antibiotics. Antibiotics are selectively toxic against bacteria because bacterial cells differ greatly from human cells. One of the chief differences is that bacteria, unlike animal cells, have a *cell wall.* This wall is a rigid structure that forms the cell's outer boundary.

The type of cell wall a bacterium has is one factor that determines which antibiotics can kill it. Scientists use a process called *Gram staining* to classify cell walls of bacteria. Hans C. J. Gram, a Danish bacteriologist of the late 1800's, developed the process. This method classifies bacteria as *gram-positive* (G+) or *gram-negative* (G−).

Some antibiotics selectively kill either gram-positive bacteria or gram-negative bacteria. These substances are called *narrow spectrum antibiotics.* The antibiotic Vancomycin *(VAN koh MY sihn)* selectively kills such gram-positive bacteria as *Staphylococcus (STAF uh luh KAHK uhs), Streptococcus (STREHP tuh KAHK uhs),* and *Enterococcus (EHN tuhr oh KAHK uhs).* Aztreonam *(az TREE oh nahm)* is a narrow spectrum antibiotic that kills only gram-negative bacteria, such as *Escherichia coli (EHSH uh RIHK ee uh KOH ly)* and *Pseudomonas aeruginosa (soo duh MOH nas ih ROO juh NOH suh).* Other antibiotics can kill both gram-positive and gram-negative bacteria. These drugs are called *broad spectrum antibiotics.* Ceftriaxone *(sehf try AHKS ohn)* is one example of a broad spectrum antibiotic. No broad spectrum antibiotic can kill all bacteria, and no narrow spectrum antibiotic can kill all gram-positive or all gram-negative bacteria.

Other kinds of antibiotics. Some antibiotics are effective against infections caused by fungi and protozoans, whose cells differ from human cells. Antibiotics that fight fungi include miconazole *(mih KAHN ah zohl)* and amphotericin *(AM fuh TEHR uh sihn).* Paromomycin *(PAR oh moh MY sihn)* is used to treat amebiasis *(AM uh BY uh sihs),* an intestinal disease caused by a protozoan.

Anticancer antibiotics attack cells while they are dividing. These drugs are somewhat selectively toxic because cancer cells generally divide much more frequently than do normal cells. But some normal cells—such as blood-forming cells—divide rapidly. Anticancer antibiotics also affect these cells. The antibiotic doxorubicin *(DAHK soh ROO buh sihn)* is used to treat certain types of leukemia, breast cancer, and other tumors.

How antibiotics work

Antibiotics fight microbes and cancer cells by interfering with normal cell functions. In most cases, this interference occurs in one of three ways: (1) prevention of cell wall formation, (2) disruption of the cell *membrane* (covering), and (3) disruption of chemical processes.

Prevention of cell wall formation. Penicillins and some other antibiotics destroy microbes by interfering with their cell wall formation. Animal cells do not form walls. As a result, these antibiotics do not damage them.

Disruption of the cell membrane. All cells have a membrane that controls the movement of substances in and out of the cell. Some antibiotics, including ampho-

tericin B and nystatin, disrupt the cell membrane of certain microbes. A damaged membrane might allow vital nutrients to escape or poisonous substances to enter and kill the cell. These antibiotics do not harm human cells because the drugs affect membrane components found only in microbial cells.

Disruption of chemical processes. All cells produce proteins and nucleic acids, which are vital to life. Human cells produce these substances in much the same way as microbial cells do. But in some cases, these processes differ enough so that antibiotics interfere with the chemical activities in microbial cells, but not in human cells. For example, streptomycin *(STREHP tuh MY sihn)* and tetracycline *(TEHT ruh SY klihn)* prevent certain kinds of microbes from producing proteins, and rifampin *(RIHF am pihn)* interferes with the formation of nucleic acids.

Dangers of antibiotics

Many antibiotics are regarded among the safest drugs when properly used. But antibiotics can sometimes cause unpleasant or dangerous side effects. The three main dangers are (1) allergic reactions, (2) destruction of helpful microbes, and (3) damage to organs and tissues.

Allergic reactions, in most cases, are mild and produce only a rash or fever. But severe reactions can occur, and can even cause death. All antibiotics are able to produce allergic reactions, but such reactions occur most often with penicillins. A physician usually asks if a patient has ever had an allergic reaction to an antibiotic before prescribing that drug. Most people who are allergic to one antibiotic can take other antibiotics that have significantly different chemical compositions.

Destruction of helpful microbes. Certain areas of the body commonly harbor both harmless and pathogenic microbes. These two types of microbes compete for food, and so the harmless microorganisms help restrain the growth of those that cause disease. Many antibiotics—especially broad spectrum drugs—do not always distinguish between harmless and dangerous microbes. If a drug destroys too many harmless microorganisms, the pathogenic ones will have a greater chance to multiply. This situation can lead to a new infection called a *superinfection*. Physicians usually prescribe a second drug to combat a superinfection.

Damage to organs and tissues is rare in people using antibiotics that act only against the cells of pathogenic microbes. Extensive use of some antibiotics, however, may damage tissues and organs. For example, streptomycin has caused kidney damage and deafness. Physicians prescribe drugs with such known risks only if no other drug is effective.

Anticancer antibiotics act against all cells that divide rapidly, and so can affect normal cells as well as cancer cells. For example, cells in the bone marrow divide constantly to produce fresh blood cells. Anticancer antibiotics can damage the bone marrow. Such damage increases the risk of infection by reducing the number of white blood cells, which help the body fight disease.

Some widely used antibiotics

Antibiotic	Some infections and diseases treated
Ampicillin	G+ and G– infections, including respiratory infections and urinary tract infections.
Ceftriaxone	G+ and G– infections, including gonorrhea.
Chloramphenicol	Rocky Mountain spotted fever and G+ and G– infections, including meningitis.
Ciprofloxacin	Urinary tract infections and acute diarrheal diseases caused by certain G– infections.
Dicloxacillin	Penicillin-G resistant, methicillin-sensitive staphylococcal infections.
Doxycycline	Pneumonia, G+ and G– infections, bite wounds, acne.
Azithromycin	Many kinds of pneumonia, and certain other G+ infections.
Gentamicin	Serious infections, especially G- infections.
Neomycin	G+ and G– infections, especially skin infections and those resulting from burns.
Fluconazole	Fungus infections of the skin, mucous membranes, blood, and brain.
Penicillin G	Syphilis, strep throat, and other G+ infections.
Rifampin	Tuberculosis.
Streptomycin	Tuberculosis and bubonic plague.
Vancomycin	Serious staphylococcal, enterococcal, and streptococcal infections that resist other drugs.

Resistance to antibiotics

Some pathogenic microbes develop an ability to resist the effects of certain antibiotics. The most widespread and worrisome resistance in pathogenic microbes occurs in bacteria.

Bacteria can become resistant to antibiotics through a type of evolution. In bacteria—as in other living things—*genes* carry instructions controlling life processes. Occasionally, a gene in a bacterium naturally changes in a way that enables the microbe to resist the effects of an antibiotic. Such a change is called a *mutation*. The change may provide resistance to one specific antibiotic or to a group of chemically similar antibiotics—for example, the penicillins. Bacteria can also acquire resistance from other bacteria by transferring genetic material. In some cases, these exchanges enable bacteria to acquire resistance to more than one type or more than one group of antibiotics.

Bacteria also can become resistant to antibiotics by producing an enzyme that breaks down the drug. This occurs with *Staphylococcus*, which may resist penicillins and cephalosporins *(SEHF uh luh SPAWR ihnz)*. Bacteria can also change their cell membranes so that antibiotics can not penetrate them. An example of this kind of bacteria is *Pseudomonas*. *Pseudomonas* may develop resistance to the quinolone antibiotics this way. *Enterococcus*, a gram-positive bacteria, can become resistant to vancomycin by changing the proteins to which vancomycin usually binds. *Streptococcus* can resist penicillins and cephalosporins in this way.

Testing and producing antibiotics

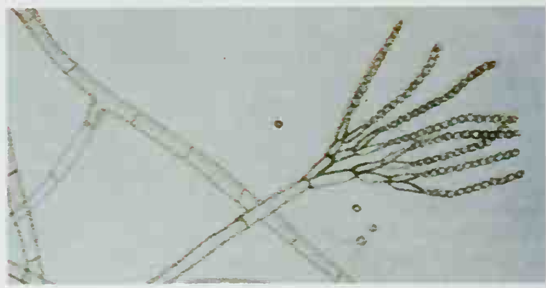
Testing. Every year, scientists test thousands of natural and chemically modified microbial substances for potential use as antibiotics. First, they test these substances against harmful microbes or cancer cells that have been grown either in test tubes or on laboratory plates.

A substance that shows strong antibiotic activity against pathogenic microbes or cancer cells undergoes extensive tests in laboratory animals. If it produces no harmful effects in the animals, scientists test the antibiotic in human beings. In the United States, the Food and

Drug Administration (FDA) must approve human testing. If the drug proves to be safe and effective, it is referred to the FDA for approval. Finally, if the FDA approves the antibiotic, the developer begins to produce it for sale.

Production of antibiotics involves several steps. First, cultures of antibiotic-producing microbes are grown in flasks and then transferred to huge fermentation vats (see Fermentation). The microbes multiply rapidly in the vats because the environment is controlled to stimulate their growth. After fermentation, the antibiotic substance is extracted from the culture and purified.

Some natural antibiotic substances are modified chemically to produce semisynthetic antibiotics. Many such drugs are more effective than the natural antibiotics from which they were developed.



Drug companies conduct special tests on antibiotics during and after production to ensure their quality. Finally, manufacturers make the purified antibiotic substances into pills, liquids, and ointments for medical use.

History

For more than 2,500 years, people have treated certain skin infections with molds that form antibiotics. However, modern scientific study of these substances did not begin until the late 1800's. At that time, the French chemist Louis Pasteur discovered that bacteria spread infectious diseases. Then Robert Koch, a German bacteriologist, developed methods of isolating and growing various kinds of bacteria. Koch also identified specific bacteria that cause certain diseases.

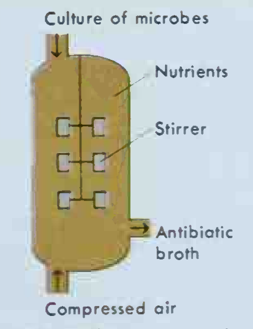
Scientists then began working to develop drugs that could destroy pathogenic microbes, but the substances they produced proved either ineffective or dangerous. A historic breakthrough came in 1928, when British bacteriologist Alexander Fleming observed that a mold of the genus *Penicillium* produced a substance that destroyed bacteria. He called the substance *penicillin.*

In the early 1940's, American bacteriologist Selman A. Waksman tested about 10,000 types of soil bacteria for antibiotic activity. In 1943, he discovered that some

Taurus

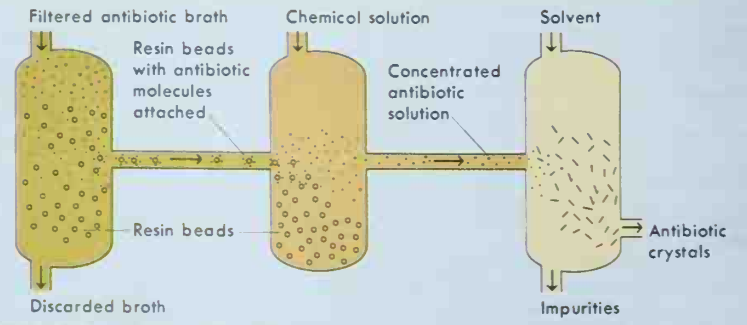
Penicillin became the first effective antibiotic. It is obtained from *Penicillium* mold and then purified and crystallized. This photo gives a microscopic view of *Penicillium* mold.

Streptomyces (strehp tuh MY seez), a type of fungi, produced a substance that had potent antibiotic properties. A new antibiotic called *streptomycin* resulted from Waksman's research. Thousands of antibiotic substances have been found in nature or have been produced chemically. Relatively few antibiotic substances, however, have proved safe and effective.



Since the 1990's, resistance to antibiotics has been a growing threat to public health. Widespread use of antibiotics to treat human infections increases the number of resistant bacteria. Antibiotic use in livestock promotes the development of resistant bacteria that can spread to humans. For example, studies in the Netherlands, Spain, the United States, and the United Kingdom in the late 1990's revealed that many chickens were infected with antibiotic resistant strains of a bacterium called *Campylobacter (KAM py loh BAK tur).* When people cooked the meat of these chickens, some of the Campylobacter microbes survived, and the people became infected.

Certain kinds of *Enterococcus* bacteria are especially troublesome because of their resistance. In Europe, drug-resistant *strains* (types) of *Enterococcus* that originated in livestock have spread to people. In the United States, *Enterococcus* resistant to multiple antibiotics has



How antibiotics are produced

Drug manufacturers produce millions of tons of antibiotics yearly, and the production process varies among companies. Some drug firms use the process shown here. The companies conduct extensive tests during and after production to make sure the antibiotics are safe and effective.

WORLD BOOK diagram by Arthur Grebetz

Fermentation causes a culture of microbes to grow rapidly and produce antibiotic broth. Stirring, air, and nutrients help stimulate growth.

Purification. Antibiotic broth is filtered into a tank containing substances called *resin beads.* Antibiotic molecules separate from impure elements in the broth and attach onto the resin beads. The remaining broth is flushed from the tank. A chemical solution is added to force the beads to the bottom of the tank, and the concentrated antibiotic solution flows into another tank. There, a solvent causes the solution to form pure antibiotic crystals.

caused human infections that are difficult or impossible to treat. Infections caused by antibiotic-resistant varieties of *Enterococcus* occur mostly in patients who are already seriously ill.

In the 1990's, scientists combined the antibiotics quinupristin and dalfopristin to create a drug that works against resistant strains of *Enterococcus*. In 2000, the FDA approved *linezolid (lyn AY zoh lid),* the first entirely new type of antibiotic developed in more than 30 years. The antibiotic is effective against gram-positive bacteria, including *Enterococcus,* that have become resistant to all other antibiotics. But experts believe antibiotic-resistant *Enterococcus* remains a major threat to public health. Melanie Johns Cupp

Antichrist is a power or person opposed to Jesus Christ. According to the Bible, the Antichrist will rise to power before the Last Judgment, but will then be defeated by Christ. The idea of such a final war between good and evil occurred among Babylonians, Persians, and Jews before being adopted by Christians. The term *Antichrist* appears only in the First and Second Epistles of John. The concept of the Antichrist appears in various passages in the New Testament. For example, it is symbolized in the Book of Revelation as a beast—a form of Satan. Joseph M. Hallman

Anticoagulant, *AN tee koh AG yuh luhnt,* is a chemical substance used to prevent the normal *coagulation* (clotting) of blood. The chief types are (1) drugs that slow clotting in a person's bloodstream and (2) substances that prevent the clotting of blood in a test tube.

Anticoagulant drugs are administered to treat and prevent blood clots. They often are used in the treatment of *thrombophlebitis,* the formation of a clot in a damaged vein (see **Phlebitis**). When a vein is damaged, a series of reactions changes an inactive blood chemical called *prothrombin* into *thrombin.* Thrombin, in turn, helps cause the formation of *fibrin,* the protein that makes up the most important part of a clot. Anticoagulant drugs reduce the speed of one of these steps. For example, *dicoumarol* slows the conversion of prothrombin into thrombin.

Certain anticoagulants are added to blood stored for transfusions and to blood samples used for laboratory tests. These anticoagulants work by joining with calcium ions in the blood. Free calcium ions must be in the blood for clotting to occur. Edward E. Morse

Anticonvulsant is a type of drug used to treat or prevent seizures. Seizures are episodes of overactive brain function in which people may lose consciousness or experience sensory or emotional disturbances. Convulsions are a type of seizure during which violent, involuntary muscle contractions occur. Anticonvulsants are the primary drugs for treating epilepsy, a disease that involves recurring seizures.

Scientists do not know exactly how anticonvulsants work. During a seizure, excessive electrical activity takes place in the brain. This activity can begin in widespread areas of the brain, or it can start in limited parts of the brain and spread to other parts. Scientists think anticonvulsants may prevent the electrical activity from starting or reduce its spread to other parts of the brain.

Throughout history, people have used many magical, religious, or medicinal agents to attempt to prevent seizures. During the 1800's, drugs called *bromides* were found to be somewhat effective against seizures. However, bromides often caused mental disturbances and other harmful side effects. The use of bromides as anticonvulsants ended in the first half of the 1900's, when safer and more effective drugs were introduced. These drugs included phenobarbital (Luminal) and phenytoin (Dilantin). Other anticonvulsants widely used today include carbamazepine, clonazepam, and valproic acid.

Some anticonvulsants are taken only by mouth. Others are usually taken by mouth but also may be injected into a vein. All anticonvulsants are very powerful and should only be used under the supervision of a doctor. N. E. Sladek

Anticosti, *AN tuh KAW stee,* is a rocky island in the Gulf of Saint Lawrence, off the southern coast of Quebec. Anticosti has an area of 3,059 square miles (7,923 square kilometers) and a population of 266. The French explorer Jacques Cartier reached Anticosti in 1534. The government of Quebec owns Anticosti. The island is used for hunting, fishing, and vacationing. It has a herd of more than 100,000 white-tailed deer. Roger Nadeau

Anti-Defamation League. See B'nai B'rith.

Antidepressant is the name of a group of drugs commonly used to treat major depression, a severe mental illness. Antidepressants also help treat other disorders, including chronic pain, anxiety disorders, and obsessive-compulsive disorder. See **Depression; Mental illness.**

Antidepressants are thought to work by regulating the brain's neurotransmission system. Chemicals called *neurotransmitters* carry messages from one nerve cell in the brain to another. These chemicals attach to special molecules on nerve cells called *receptors,* both in sending and receiving messages. Antidepressants first increase the concentration of neurotransmitters in the brain. After several weeks of treatment, the receptors become less sensitive, and depression lifts.

The three main types of antidepressants are (1) *selective serotonin re-uptake inhibitors* (SSRI's), (2) *tricyclic antidepressants* (TCA's), and (3) *monoamine oxidase inhibitors* (MAOI's). SSRI's and TCA's prevent brain cells from reabsorbing excess neurotransmitters after the chemicals have delivered their messages. SSRI's block the reabsorption of the neurotransmitter called *serotonin.* SSRI's include the most widely prescribed antidepressant, fluoxetine (Prozac). TCA's, such as the drug amitriptyline (for example, Elavil), block the reabsorption of several neurotransmitters, including serotonin and

norepinephrine. MAOI's, which include the drug phenelzine (Nardil), inactivate a protein that breaks down excess neurotransmitters.

Most antidepressants are taken by mouth, and all require the prescription of a doctor. The drugs may cause various side effects. For example, SSRI's can cause increased anxiety, poor sleep, nausea, and loss of sexual interest. TCA's can cause *hypotension* (low blood pressure), irregular heartbeat, and constipation. MAOI's may combine with certain foods or drugs to create life-threatening *hypertension* (high blood pressure).

Alan M. Gruenberg

Antidote, *AN tee doht* or *AN tih DOHT,* is a substance that fights the harmful action of a poison in the body. Some antidotes act chemically on poisons to make them harmless. Other antidotes produce an action that works against the action of the poison. Still other antidotes can prevent certain body cells from reacting to the effects of a poison. *Antitoxins* are a special kind of antidote (see **Antitoxin**).

Most antidotes are effective against only one kind of poison. But they usually have either a worsening effect or no effect at all when used against another type of poison. For this reason, a doctor should be called immediately in any case of poisoning. David R. Boyd

Antietam, Battle of. See **Civil War** (Battle of Antietam).

Anti-Federalists were a political group in the United States in the late 1780's that feared a strong national government. Many opposed the adoption of the U.S. Constitution. Others voted for it but said it should be interpreted to give the national government the least possible power. In the 1790's, the name *Anti-Federalist* was sometimes applied to Thomas Jefferson's followers, who wanted to limit the growth of the central government's power. Donald R. McCoy

Antifreeze is a substance that is added to a liquid to lower its freezing point. Antifreezes are used in compounds that remove ice or prevent it from forming, and in refrigerants and heat-transfer fluids. This article discusses automotive antifreezes, which are added to an automobile engine's cooling system.

An automobile engine operates at extremely high temperatures. It is cooled by fluid circulating through a cooling system. This prevents the engine from overheating, which can result in engine damage. Previously, water alone was used in the cooling system during the summer, and antifreeze was added to the water during the winter. Today, however, automobiles are designed to use a mixture of equal parts of water and antifreeze as the coolant the year around. Antifreeze prevents the water from freezing in cold temperatures. Modern antifreezes also raise the boiling point of the water. The cooling system therefore can operate at higher temperatures without the risk of boiling. The cooling system also operates more efficiently at higher temperatures.

Such materials as kerosene, honey, salt water, and methyl alcohol were once used as antifreezes, but these substances can damage a car's engine. Today, most automotive antifreezes are composed chiefly of a liquid compound called *ethylene glycol* (see **Glycol**). Automotive antifreezes also contain chemicals that protect the metal parts of the engine's cooling system from corrosion. Kathleen C. Taylor

Antigen. See **Immune system**.

Antigone, *an TIHG uh nee,* in Greek mythology, was the daughter of King Oedipus and Queen Jocasta, the rulers of Thebes. Oedipus had unknowingly killed his father and married his mother. When he discovered what he had done, he blinded himself and was banished from Thebes. Antigone accompanied her father and served as his guide during his exile (see **Oedipus**).

Following Oedipus' death, Antigone returned to Thebes, where her brothers Eteocles and Polynices were struggling for the throne. The brothers had agreed to share the rule of Thebes, but Eteocles broke the agreement. Polynices tried to regain his share of the throne by attacking the city in an episode called the Seven Against Thebes.

During the battle, Eteocles and Polynices killed each other. Creon, the new king, buried Eteocles with great honor. But he considered Polynices a rebel and a traitor and forbade anyone to give him a proper burial. Antigone considered Creon's order a violation of divine law and buried her brother.

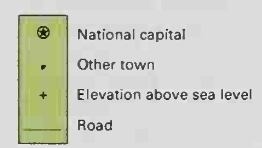
The British Museum

Antigone was a princess in Greek mythology. She gave her brother Polynices an honorable burial against the wishes of King Creon of Thebes. This painting on a Greek vase shows Creon, *left,* sentencing Antigone, *right,* to death for her disobedience.

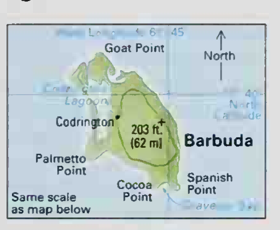
Creon sentenced Antigone to death for her disobedience, despite the pleas of his son Haemon, whom Antigone was to marry. Ancient sources differ on what finally happened to her. One says she and Haemon committed suicide. Others say she was killed by Creon or went into exile. Antigone has come to represent personal courage and conscience, especially in opposing the unjust use of power by the state. Nancy Felson

Antigonid dynasty, *an TIHG oh nihd,* was the name of a line of kings that ruled Macedonia, a kingdom north of Greece. The Antigonid rule lasted from 294 B.C. to

168 B.C. The family's first powerful ruler was Antigonus I, a general under Alexander the Great. Alexander died in 323 B.C., and Antigonus seized a part of Alexander's empire in present-day Turkey, Syria, and Iraq. Antigonus tried to seize more of the empire, but he was defeated and killed at the Battle of Ipsus in 301 B.C. In 294 B.C., his son Demetrius I became the first Antigonid to rule Macedonia. In 277 B.C., Antigonus II saved Macedonia from Celtic invaders. Philip V, grandson of Antigonus II, challenged Rome and became an ally of Hannibal of Carthage. But Philip was defeated in 197 B.C. The Romans ended the Antigonid rule by defeating Perseus in 168 B.C. Thomas W. Africa

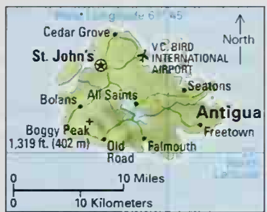


Antigravity is a hypothetical force of repulsion. It is described in some science-fiction stories but has not been observed by scientists. In theory, antigravity would resemble gravity except that it would cause objects to repel, rather than be attracted to, one another. For example, gravity on the earth pulls objects toward the planet's center. But antigravity, if it existed, would push objects away from the earth's center.



Some people have speculated that, because electric forces can be attractive or repulsive, gravitational force also may be either attractive or repulsive. However, electric force can be attractive or repulsive because it is proportional to electric charge, which is either positive or negative. For this reason, like charges repel and unlike charges attract. Gravitational force, on the other hand, is proportional to *mass* (the amount of matter that makes up an object). Mass is always positive and has no known negative counterpart. Therefore, it seems that gravitational force must always be attractive.

It is possible, however, that evidence of antigravity will be provided by observations of *antimatter* (see **Antimatter**). A few scientists have speculated that antimatter will fall *up*. No one has yet been able to observe freely falling antimatter. But other experiments have led most physicists to conclude that antimatter, just like matter, must fall toward the center of the earth. Joel R. Primack



Antigua, *ahn TEE gwuh* (pop. 30,000), formerly Antigua Guatemala, was the capital of Guatemala in colonial days. The city was founded in 1543. It is west of the present capital, Guatemala City (see **Guatemala** [map]). In 1773, an earthquake destroyed Antigua. The capital was moved to its present site in 1776. Antigua's colonial ruins attract many tourists. Gary S. Elbow

Antigua and Barbuda

WORLD BOOK maps

Antigua and Barbuda, *an TEE guh* or *an TEE gwuh, bahr BOO duh* or *bahr BYOO duh,* is an island country in the Caribbean Sea. It consists of three islands—Antigua, Barbuda, and Redonda. The islands lie about 430 miles (692 kilometers) north of Venezuela.

Antigua and Barbuda has a total land area of 171 square miles (442 square kilometers) and a population of about 69,000. The island of Antigua covers 108 square miles (280 square kilometers); Barbuda, 62 square miles (161 square kilometers); and Redonda, only $\frac{1}{2}$ square mile (1.3 square kilometers). About 98 percent of the people live on Antigua and 2 percent on Barbuda. Redonda is uninhabited. St. John's (pop. 36,000), on the northwest coast of Antigua, is the country's capital and largest city. The East Caribbean dollar is the country's basic unit of currency. For a picture of the flag of Antigua and Barbuda, see **Flag** (Flags of the Americas).

Government. Antigua and Barbuda is a constitutional monarchy and a member of the Commonwealth of Nations (see **Commonwealth of Nations**). A prime minister heads the government. The prime minister and a Cabinet conduct government operations. A 17-member Parliament—composed of a House of Representatives and Senate—makes the laws. The people elect the Parliament members. The head of the majority party of the House of Representatives serves as prime minister. The prime minister appoints the Cabinet members.

People. The vast majority of the people of Antigua and Barbuda are descendants of black Africans. About half of the people live in St. John's, and most of the rest live in rural areas. Most of the people live in one-story

J. Alex Langley, DPI

Antigua and Barbuda is a nation in the Caribbean Sea that consists of three islands. Many tourists visit the islands each year to enjoy the beautiful beaches, clear water, and warm, sunny climate.

houses made of concrete blocks or wood. They wear clothing similar to that worn in the United States and other Western nations. Their main foods include beans, fish, lobsters, and sweet potatoes.

Almost all the people of Antigua and Barbuda speak English, the nation's official language. Most of the people are Protestants. Anglicans make up the largest Protestant group. Antigua and Barbuda has well-developed primary and secondary educational systems.

Land and climate. The islands of Antigua and Barbuda are mostly flat. They were formed from volcanoes that were worn down by wind and rain. The islands have beautiful beaches covered with white sand. Antigua's coast has numerous bays and inlets. Redonda is rocky and has little plant life. The average temperature of the islands is 80 °F (27 °C). The islands receive about 45 inches (114 centimeters) of rain annually. However, long periods of drought strike the area from time to time.

Economy. Tourism ranks as the major economic activity of Antigua and Barbuda. The country's beaches, resorts, and warm sunny climate attract tourists from many lands. The tourist industry employs most of Antigua and Barbuda's people. Sugar is also important to the country's economy. Farmers raise sugar cane, and processors refine it into sugar. Cotton is another major product. The country's crop production is often harmed by droughts. As a result, the government encourages the development of small industries to strengthen the economy. The country's industries make clothing, paint, and such appliances as refrigerators and stoves.

History. Carib Indians were the first inhabitants of Antigua and Barbuda. In 1493, Christopher Columbus became the first European to reach Antigua. British settlers established a colony on Antigua in 1632. The colony, which later included Barbuda and Redonda, was called Antigua. The British brought African slaves to the islands to work on sugar cane plantations. The slaves were freed in 1834, the year after Britain abolished slavery throughout its empire. Most of the British people eventually left, but Britain retained control of the colony.

In 1967, the colony of Antigua became part of the West Indies Associated States and gained control of its internal affairs. It became the independent nation of Antigua and Barbuda on Nov. 1, 1981.

In 1989, Hurricane Hugo struck Antigua and Barbuda. The hurricane caused two deaths and $80 million in property damage. Another powerful hurricane, Hurricane Luis, hit the islands in 1995. It resulted in two deaths and at least $300 million in property damage.

Thomas G. Mathews

Antihistamine, *AN tee HIHS tuh meen,* is the name of a group of drugs used to treat symptoms of allergies. These symptoms include irritated eyes, runny nose, sneezing, and hives. Antihistamine drugs work by counteracting the effects of *histamine,* a substance found in many body cells. Excessive or inappropriate release of histamine into body fluids can cause allergies such as hay fever and contribute to dangerous reactions to insect bites and certain medications. Antihistamines are also used to treat motion sickness.

Chemists working in France developed the first useful antihistamines in the early 1940's. Diphenhydramine, a common antihistamine drug, was developed in the United States in 1943. People can purchase diphenhydramine, known by such trade names as AllerMax and Benadryl, and many other antihistamines without a doctor's prescription. Nonprescription antihistamines are sold to promote sleep and relieve cold symptoms, as well as to treat allergies.

A common side effect of many antihistamines is drowsiness. For this reason, people are advised not to drive or operate heavy machinery while using the drugs. In the 1970's and 1980's, scientists developed the first antihistamines that did not cause drowsiness. The first such drug available in the United States was terfenadine, which was sold until 1997 under the trade name Seldane. Another similar drug is astemizole, known by the trade name Hismamal. Drugs of this type are much more expensive than older antihistamines. In rare cases, they have caused irregular heartbeats. These drugs are available only with a doctor's prescription.

Richard W. Sloan

Antilles. See West Indies.

Anti-Masonic Party, *AN tee muh SAHN ihk,* was an American political organization that was active during the late 1820's and early 1830's. It was one of the earliest American third party movements. The movement began in 1826 when William Morgan, a New York Mason, disappeared mysteriously after threatening to reveal Masonic secrets. Many people believed Masons had kidnapped and murdered him. Anti-Masonic feelings swept through New York and nearby states, and a political party was organized.

In 1831, the Anti-Masonic Party held the first national nominating convention in United States history. The party's presidential candidate, William Wirt, received only seven electoral votes in the 1832 election. However, the Anti-Masonic Party won the Vermont governorship and elected several congressmen. The party then declined. Most of its members joined the Whig Party.

Richard E. Ellis

Antimatter is matter composed of elementary particles that are the opposite of ordinary particles. These opposite particles are called *antiparticles.* An antiparticle exactly resembles its corresponding ordinary particle in every property except its charge, which is reversed. For example, an electron is an ordinary particle that has a negative electric charge. Its antiparticle, a positron, exactly resembles it except that a positron carries a positive electric charge. In addition, antiparticles combine in the same way that ordinary particles do. For example, an antineutron may combine with an antiproton and so form an antideuteron, the nucleus of an antideuterium atom.

The British theoretical physicist Paul A. M. Dirac first described antimatter in 1930, before anyone had discovered or produced it. Since then, physicists using high-energy particle accelerators have produced various antiparticles, including positrons, antineutrons, and antiprotons.

In 1996, physicists at the CERN laboratory near Geneva, Switzerland, announced that they had created the first known atoms of antimatter. These were atoms of antihydrogen. Each atom was made up of a nucleus consisting of a single antiproton, with a positron in orbit about the nucleus.

When an ordinary particle collides with its antiparticle, the two parties destroy each other, releasing en-

ergy. If an extremely large amount of energy is released, some of this energy forms another particle and antiparticle. This collision is called *annihilation.* Such collisions may explain the apparent absence of naturally occurring antimatter in the universe. Many scientists speculate that the universe began with an explosion—called the *big bang*—and that there was slightly more matter than antimatter immediately after the explosion (see Cosmology [Radio waves in space]). According to this theory, the matter in the universe today is the tiny remnant left after all the antimatter annihilated with most of the matter.

Anti-Monopoly Party was active in U.S. politics in 1884. The party opposed monopolies in business. In 1884, it joined with the Greenback Party in backing Benjamin F. Butler of Massachusetts for president. The party broke up after Butler received only 175,000 votes. See also **Butler, Benjamin F.** Donald R. McCoy

Antimony, *AN tuh MOH nee,* a chemical element, is a bluish-white, brittle metal. It is used to harden and strengthen lead. Antimony-lead alloys are used in some electric cables and batteries. Compounds containing antimony are used in producing materials used in refrigerators, air conditioners, aerosol sprays, paints, and flameproofing agents.

Antimony is most commonly found combined with sulfur in the mineral *stibnite.* Pure antimony can exist as metallic antimony—the more common form—and as a black powder, known as black or gray antimony.

Antimony has the chemical symbol Sb, from *stibium,* the old name for the element. Its atomic number is 51 and its atomic weight is 121.760. Its density is 6.691 grams per cubic centimeter at 20 °C. Antimony melts at 630.74 °C and boils at 1586.85 °C. It conducts electricity better in its liquid form than as a solid.

Antimony has been used for thousands of years. The ancient Egyptians used substances containing antimony as cosmetics and medicines. The Bible and ancient writings from China, India, and Mexico also refer to medical uses of antimony preparations. Raymond E. Davis

Antioch, *AN tee AHK* (pop. 123,900), is a commercial city in Turkey. Its name in Turkish is Antakya (pronounced *ANT uh KYAH*). Antioch lies along the Orontes River, about 7 miles (11 kilometers) from the Mediterranean (see **Turkey** [political map]). The city was founded about 300 B.C. by Seleucus, the ruler of the area. It was the capital of Syria during the A.D. 900's and 1000's. The Ottoman Empire captured Antioch in 1516. France took control of the city after the Ottoman Empire was defeated in World War I (1914-1918). In 1939, Antioch became a part of the Republic of Turkey. F. Muge Gocek

Antioxidant, *AN tee AHK suh duhnt,* is any of a group of chemical compounds that may prevent certain types of cell damage. Antioxidants block the effects of *oxidation,* a chemical reaction in which a substance loses electrons, often while combining with oxygen. Antioxidants are important because they protect cells from the effects of *free radicals,* unstable molecules produced by oxidation. Scientists believe free radicals may be involved in the aging process as well as in a number of diseases.

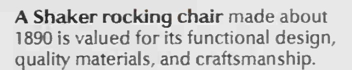
In the human body, cells create free radicals when oxygen combines with food molecules to produce energy. Radiation, cigarette smoke, and air pollution also trigger the production of free radicals. Free radicals can attract and "steal" electrons from almost any nearby molecule to replace the electrons they lost during oxidation. Such attacks can damage the cell and can cause changes in genes. Antioxidants are the body's defense against free radicals. An antioxidant can provide an electron to a free radical before the free radical attacks important cell structures.

The body naturally produces certain enzymes that are antioxidants. In addition, vitamins C and E and certain plant chemicals, such as *carotenoids* and *flavonoids* (often called *bioflavonoids*), are antioxidants.

Fruits and vegetables are rich sources of dietary antioxidants. Citrus fruits are a rich source of vitamin C. Vitamin E is found in vegetable oils and nuts. Foods plentiful in beta-carotene or other carotenoids tend to be deep yellow or green, such as carrots and spinach. Flavonoids occur in many fruits and vegetables. Some studies have connected a diet rich in antioxidants with a reduced risk of cancer, heart disease, cataracts, and other diseases common among older people. Scientists are trying to determine if these reduced risks are due to the antioxidants or to some other factor.

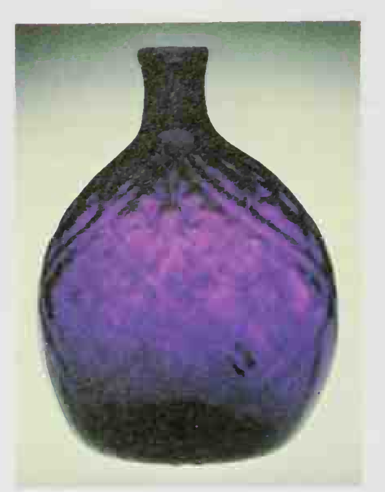
Antioxidants also have commercial uses. They are added to foods to prevent spoilage. Synthetic antioxidants are used to prevent oxidation in gasoline, rubber, and other products. Jeffrey B. Blumberg

Antiperspirant. See **Deodorant.**



Antique is an object from the past that has artistic or historical value. Antiques are commonly called *decorative arts.* They range from everyday household items to commissioned pieces not intended for personal use.

Opinions differ as to what is an antique. However, experts consider three factors in judging the quality of a piece and its value as an antique: (1) its age, (2) its artistic value, and (3) its historical importance. According to the United States government, which levies no import tax on antiques, an item must be more than 100 years old to be an antique. Most collectors also use this standard.



Antiques differ from *antiquities* and the *fine arts.* Antiquities are items created by ancient cultures. The fine arts include architecture, painting, and sculpture. However, the lines separating antiques, antiquities, and the fine arts are not always clear. Commercial objects known as *collectibles*—such as advertising items, postcards, and baseball cards—are also popular. They are not considered antiques.

Collectors seek out antiques for pleasure, investment, or profit. Museums and other institutions exhibit antiques. The variety of antiques is enormous. For example, people collect quilts, needlework, embroidery, costumes, clocks, arms and armor, musical instruments, dolls, toys, games, and lighting devices. However, antiques generally fall into four major categories—ceramics, furniture, glass, and metalwork. This article discusses these categories and their history in America.

Ceramic antiques usually are divided into two categories—pottery and porcelain. Porcelain, commonly called china, is hard, thin, and usually white. Pottery is any type of ware made from baked clay. Porcelain was not made in America until the late 1700's. Until then, the colonies imported it from China and Europe. Colonists

Clock (about 1820) probably made by Eli Terry or Seth Thomas; Shelburne Museum, Shelburne, Vt.

A shelf clock made in New England in the early 1800's had a scroll top and thin pillars on the sides.

began making pottery in the 1600's because pottery making required simpler technology and clay was available. Many early pieces are decorated with painted flowers, animals, and other designs. Many of these pieces have a delightful simplicity and are collected by folk art enthusiasts.

Furniture was made by some of the earliest European settlers in America, who brought their homeland traditions in cabinetmaking with them. Few pieces remain from the 1600's. Surviving pieces from the 1600's and 1700's often can be linked to a particular region. For example, the *kas* (large wardrobe) was made by the Dutch in New York and New Jersey. A style of furniture made from about 1790 to 1830 is called the Federal style or American Federal. Furniture makers worked in such urban centers as Baltimore, Boston, Charleston, S.C.; New York City, Newport, R.I.; and Philadelphia. The showy, highly decorated pieces from the Victorian Age (1837-1901) have become valuable. However, pieces crafted in a highly individual rural style are also prized.

Glass. In the 1600's, several glassmaking factories opened in what is now the United States. But they all soon failed. The first successful factory to produce blown glass opened in 1739. In the mid-1700's, colonial factories also began making *blown-molded glass,* which was glass shaped by being blown into a mold. During the 1820's, American glassmakers invented the method of making *pressed glass.* Pressed glass was liquid glass that was pressed into a mold by a mechanical plunger.

Metalwork. Antique American gold is extremely rare, but antique silver is not. Silversmiths were well established in the colonies and silver was a symbol of wealth. Many silver *tankards* (large drinking mugs) bear engraved decorations, such as coats of arms, monograms, designs, and inscriptions. In the British tradition, most silversmiths labeled their wares with their own unique mark. Because of its affordability, pewter was made in America in large quantities. Pewterers, too, often marked their wares. These marks enable collectors to trace the origins and dates of particular pieces. Other metal antiques include brass, copper, and wrought-iron household items. Painted tin called *toleware* was popular in the 1800's. Allison Eckardt Ledes

Antirenters were a group of tenant farmers in New York who fought against paying rents to the landlords. The antirenters were active from 1839 to 1847. Most landlords inherited their property from ancestors of the 1600's and 1700's. They lost feudal privileges in the Revolutionary War in America but still owned about 1,800,000 acres (320,000 hectares) of land. Almost one-fourth of this land belonged to Kiliaen Van Rensselaer, a Dutch merchant.

Tenant families had lived on the land for generations. They felt it rightfully belonged to them. Sometimes they went for years without paying rent. In 1839, the Van Rensselaer heirs tried to collect $400,000 in back rents. The angry farmers of Columbia and Delaware counties refused to pay the landlords and resisted attempts to take away their farms. They formed antirent societies. The Antirenters became so strong that they could easily defeat any political party that opposed them. In 1846, the Antirenters got the New York constitution amended in their favor. The farms were handed over to the tenants in 1847. Joan R. Gundersen

See also Patroon system.

Anti-Semitism is prejudice against Jews. However, the term is misleading because the root word *Semites* properly refers to all people who speak Semitic languages, including Arabs and some other non-Jewish peoples (see Semites).

Since ancient times, the Jews have lived as a minority group in many countries. Both Christian and Muslim nations often persecuted Jews for not accepting the religion of the majority. When economic or other conditions were bad, Jews were blamed for causing the troubles of society.

During the Middle Ages, Jews in many European countries were forced to pay special taxes and to live in segregated areas called *ghettos.* Jews also were denied the right to own land and to enter certain occupations. Some countries even expelled many Jews. In 1492, for example, the Jews were driven out of Spain.

Wilhelm Marr, a German author, coined the term *anti-Semitism* in the anti-Jewish pamphlet "The Victory of Jewry Over Germandom" (1879). The new word indicated that many people had begun to discriminate against Jews on ethnic rather than religious grounds. In the late 1800's and early 1900's, many Jews in Poland and Russia were killed in organized massacres called *pogroms.* A Jewish movement called *Zionism* developed partly in response to such persecution. The Zionists hoped to establish an independent Jewish nation in Palestine, where Jews could escape anti-Semitism. See **Zionism.**

In 1933, the Nazi dictator Adolf Hitler came to power in Germany and made anti-Semitism an official government policy. The German government stripped the Jews of their citizenship, seized their property, and sent thousands to concentration camps. By the end of World War II in 1945, the Nazis had killed about 6 million Jews in a campaign of mass murder known as the *Holocaust.*

Anti-Semitism still exists in many countries. In some countries, it affects government policies. For example, the government of Syria denies Jews the right to vote, and it restricts emigration by Jews. Yosef Levanon

Antiseptic is a substance that destroys or stops the growth of germs on living tissue. Antiseptics are applied to skin and mucous membranes to help prevent infection. They must be strong enough to fight germs but mild enough not to irritate sensitive tissues. Antiseptics differ from disinfectants and antibiotics. Disinfectants are chemicals that destroy germs on nonliving objects. Antibiotics are drugs that treat infection after it occurs.

Kinds of antiseptics. There are hundreds of antiseptic products, including creams, mouthwashes, ointments, powders, shampoos, soaps, solutions, and sprays. Each type contains a germ-fighting chemical that carries out the antiseptic action. Such chemicals include alcohols, dyes, iodophors, mercurials, phenols, and salicylamides. The kinds and amounts of chemicals that are used depend chiefly on the type of product.

The use of antiseptics. Physicians use special antiseptic cleansers to scrub their hands and to wash the patient's skin before surgery. Doctors also spray serious wounds with antiseptics in order to keep them from becoming infected.

The germ-fighting chemicals in antiseptics can cause serious side effects. These effects include a rash or some other allergic reaction, or damage to the skin. But medical experts generally believe antiseptics are safe if used as directed by the manufacturer. In the United States, the Food and Drug Administration (FDA), an agency of the federal government, regulates the manufacture and sale of antiseptics.

History. People used vinegar and wine as antiseptics as early as 2,500 years ago, long before the discovery that germs cause disease. Several hundred years ago, surgeons noticed that untreated battle wounds and surgical incisions quickly began to smell like rotting flesh. To prevent this odor, they treated the tissues with a variety of substances that became known as *antiseptics.* The word comes from two Greek words—*anti,* meaning *against,* and *sepsis,* meaning *decay.*

Through the centuries, a number of fluids and potions were used as antiseptics. In addition to vinegar and wine, they included brandy, mercury, pitch, tar, and turpentine. Some were powerful germ killers but would also harm living tissue. As a result, many patients were saved from infection but died from the treatment.

During the mid-1800's, Ignaz P. Semmelweis, a Hungarian physician, showed that a mild solution of lime chloride helped prevent infection during childbirth. Doctors who rinsed their hands in the solution kept infection from spreading among their patients. In the mid-1860's, Sir Joseph Lister, an English surgeon, pioneered the use of antiseptics in surgery. He used carbolic acid to help prevent infection in incisions. The work of Semmelweis and Lister led to the creation of many mild but effective antiseptics. Some of these products, such as alcohol and iodine, are still widely used.

Antislavery movement. See Abolition movement.

Antitoxin, *AN tee TAHK sihn,* is a substance made by living cells that counteracts illness caused by a *toxin.* Toxins are poisons produced by living organisms, such as bacteria. Doctors use antitoxins to treat diseases, including *tetanus* (lockjaw) and diphtheria. Antitoxins are a kind of *antibody* that can cure or prevent diseases or make them milder (see **Immune system**).

Many commercial antitoxins come from animals, such as horses and rabbits. Toxin is injected into an animal's bloodstream, and the animal produces an antitoxin that circulates in its blood serum. A nonpoisonous, chemically modified toxin called a *toxoid* is sometimes used to cause the body to produce antitoxin. The blood serum can be removed and then injected into patients. Most animal antitoxins are cheaper and easier to make than human antitoxins. However, animal antitoxins are less effective and may cause bad reactions.

Injected antitoxins usually do not make a patient permanently *immune* (safe from disease). The antitoxins produced by the body when a person is exposed to a

particular toxin are the most effective. In addition, body tissues produce these antitoxins again in future poisonings by the toxin. A reasonable concentration of the antitoxin usually will prevent poisoning. Antitoxins that are produced by another person also are effective in neutralizing a toxin but do not give permanent protection. Permanent immunity can be stimulated in the body by injecting toxoids. Alan R. Hinman

Antitrust laws are designed to protect competition and consumers. They prohibit *price fixing agreements,* in which business firms agree on the price they will charge for products or services. They also outlaw *mergers*—that is, the joining of business firms—that interfere with competition. In addition, antitrust laws prohibit firms from using their economic power to gain or maintain a monopoly. While the United States pioneered antitrust laws, many other nations have adopted such laws, along with freer world trade policies. In the United States, both the federal government and state governments have antitrust laws. This article discusses federal antitrust legislation.

During the late 1800's, business leaders, such as John D. Rockefeller, bought up or stamped out many of their competitors. They then brought their surviving competitors under informal common control in organizations called *trusts.* The trusts limited production and raised prices. A public outcry against abuses by the trusts led to passage of the Sherman Antitrust Act in 1890. The act outlaws any contract, combination, or conspiracy in restraint of trade. It also prohibits any person or business from monopolizing or trying to monopolize any market.

During the early 1900's, the federal government sued and broke up existing oil, tobacco, and farm machinery trusts, as well as several others. But many companies continued to grow by merging with or buying competing firms. Also, many businesses sought to eliminate competition by buying the stocks of their competitors and by forcing their customers to sign exclusive dealing contracts, or to buy goods they did not want, in order to acquire the goods they needed. Many of these practices were allowed by the courts.

In 1914, Congress responded to these practices by passing two laws that gave support to the Sherman Antitrust Act. The Clayton Antitrust Act outlaws price discrimination that gives favored buyers an advantage over their competitors. It also forbids anticompetitive agreements in which manufacturers sell only to dealers who agree not to handle the products of a rival manufacturer. In addition, the act prohibits mergers that lessen competition. The Federal Trade Commission Act established the Federal Trade Commission (FTC). This government agency works to prevent unfair and anticompetitive business practices.

Despite the Clayton Act and the Federal Trade Commission Act, companies continued to make anticompetitive mergers and acquisitions. The Celler-Kefauver Act of 1950 strengthened the Clayton Act by tightening control over mergers that reduce competition.

In 1998, the U.S. Justice Department, along with 18 state attorneys general, filed an antitrust lawsuit against the Microsoft Corporation. The lawsuit charged that Microsoft used anticompetitive practices to destroy its competitors in the computer industry. Following a 1999 trial, a federal district court judge found that Microsoft had violated antitrust laws by abusing its monopoly in personal computer operating systems. In 2001, Microsoft reached a proposed settlement with the Department of Justice and with nine of the state attorneys general. The settlement included measures to protect competition and consumer choice in the computer industry.

The late 1900's and early 2000's marked a lowering of trade barriers worldwide. As a result, opportunities for competition grew. But an increase in the number of large corporate mergers also occurred. Debate continues over whether a successful global economy requires more or less antitrust control. Some people argue that business can best respond to consumer needs if left alone. Others feel that strict enforcement of antitrust laws is necessary to protect competition and consumers. Eleanor M. Fox

See also **Monopoly and competition** (History).

Antiviral drug is the term for a group of chemical compounds used to treat diseases caused by viruses. Antiviral drugs usually do not cure viral diseases but can shorten the duration of the disease and lessen the severity of symptoms. But many antiviral drugs can cause side effects, such as anemia or kidney damage.

Many viral diseases can be prevented by using vaccines. But vaccines have not been developed for all viral diseases, and vaccines are not useful for treating people once they become ill. Other drugs, including antibiotics such as penicillin, have no effect on viruses.

Viruses use substances in the cells of living organisms, called *host cells,* to manufacture enzymes and other materials they need to reproduce. Antiviral drugs interfere with parts of the viral life cycle that are different from steps completed by the hosts. This allows drugs to attack viruses while not harming host cells. But since viruses rely on substances made by hosts to carry out many steps in their life cycles, the drugs can target only a few viral materials. Getting drugs into infected cells is also an obstacle. Despite these difficulties, researchers have developed many successful antiviral drugs.

Many antiviral drugs are chemical compounds that bind to viral enzymes, changing the structure so the enzymes cannot be used by the viruses. The drugs bind only to viral enzymes, while enzymes used by the host cell are not impaired. The virus, however, cannot reproduce to infect other host cells. The progression of the disease is thus slowed or halted by the drugs.

The first antiviral drugs were developed in the 1960's. One of the earliest, *acyclovir,* is widely used to treat infections of *herpesviruses,* a group of viruses that cause chickenpox, mononucleosis, shingles, and cold sores. This drug mimics a building block of the genetic material *DNA* (deoxyribonucleic acid) which herpesviruses need to reproduce. Viral enzymes mistakenly add this drug into a growing strand of DNA and stop its production. Acyclovir is given to patients by injection, as a pill, or in ointment applied to the skin. Other drugs, such as *zanamivir,* used to treat influenza, can be inhaled. Many antiviral drugs available today have been developed to treat HIV, the virus that causes AIDS.

Scientists are developing new antiviral drugs as they learn more about the structure and life cycle of viruses.

Researchers analyze the chemical structure of viral enzymes and proteins. They use computers to design chemical compounds that will bind to the viruses without causing side effects in the host. Nelson M. Gantz

Antoinette, Marie. See **Marie Antoinette.**

Antoninus Pius, *an tuh NY nuhs PY uhs* (A.D. 86-161), was Roman emperor from 138 until his death. He was open-minded and just, and his reign was probably the calmest period in Roman history.

Antoninus was born into a rich and influential family. He had a distinguished senatorial career. He also administered a court of appeals in Italy and served as *proconsul* (governor) of the province of Asia in western Asia Minor. Antoninus's legal experience, his wealth and reputation, and his popularity with the Senate influenced Emperor Hadrian to choose him as successor. As emperor, Antoninus left what little fighting there was to his generals. He built the Antonine Wall in northern Britain, the empire's chief trouble spot. F. G. B. Millar

Antonioni, *ahn toh nee OH nee,* **Michelangelo,** *mee kehl AHN jehl oh* (1912-), is an Italian motion-picture director. He became noted for his method of emphasizing visual symbolism instead of the plot in motion pictures. Antonioni's best films—*L'Avventura* (*The Adventure,* 1960) and *La Notte* (*The Night,* 1960)—concern people who have lost their purpose in life despite financial success.

Antonioni was born on Sept. 29, 1912, in Ferrara. He was a film critic before becoming an assistant director and film writer. He first gained recognition when he made the dramatic film *Chronicle of a Summer* (1950). He then directed *Le Amiche* (*The Girl Friends,* 1955), *The Eclipse* (1962), and *The Red Desert* (1964). He achieved international acclaim with *Blow-Up* (1966), his first English language film, and *The Passenger* (1975). Gene D. Phillips

Antony, *AN tuh nee,* **Mark** (83?-30 B.C.), a Roman general and statesman, served as co-ruler of Rome from 43 B.C. until his death. Antony and Gaius Octavian became co-rulers with Marcus Lepidus after the death of the Roman ruler Julius Caesar. Antony later married Cleopatra, the queen of Egypt, and the two combined their military forces. Antony hoped to gain sole control of Rome. However, the forces of Antony and Cleopatra lost the decisive Battle of Actium in 31 B.C.

Antony was born into an important Roman family. In 54 B.C., he became a cavalry officer under Julius Caesar. In 48 B.C., Antony helped Caesar defeat a rebel army led by Pompey the Great at the Battle of Pharsalus.

In 44 B.C., Caesar was assassinated by a group of Roman aristocrats led by Marcus Brutus and Gaius Cassius Longinus. Antony succeeded Caesar as ruler of Rome. But in 43 B.C., Octavian, the grandnephew and adopted son of Caesar, challenged Antony's rule. Later that year, Antony agreed to become a co-ruler with Octavian and Lepidus (see **Triumvirate**). They later murdered many opponents in the Senate, a group of powerful government advisers.

In 42 B.C., an army led by Antony and Octavian defeated the army of Brutus and Cassius Longinus in two battles at Philippi in Macedonia (now northern Greece). These victories were due largely to Antony's military skill. Antony then claimed Rome's eastern provinces, leaving Italy and the western provinces to Octavian.

In 41 B.C., Antony conferred with Cleopatra, whom he had met several years earlier in Rome. Antony wanted to gain sole control of Rome and hoped she would give him financial aid. They soon fell in love, and in 40 B.C., Cleopatra gave birth to twin sons by Antony. Later that year, however, Antony married Octavian's sister Octavia in order to strengthen his political position in Rome.

Antony left Octavia in 37 B.C. and soon married Cleopatra. Cleopatra had another child by Antony in 36 B.C. In 34 B.C., Antony gave a number of Rome's eastern provinces to Cleopatra and their children. Octavian convinced many Romans that Antony had behaved unpatriotically. In 32 B.C., Octavian declared war on Antony. Octavian's naval forces defeated Antony and Cleopatra's combined fleets in the Battle of Actium off the west coast of Greece in 31 B.C. Antony and Cleopatra retreated to Egypt. Soon afterward, Octavian pursued the couple. They committed suicide in 30 B.C. shortly after Octavian reached Egypt.

Antony's story is dramatized in the famous plays *Julius Caesar* (1599) and *Antony and Cleopatra* (1607) by William Shakespeare. Antony also appears as a character in John Dryden's play *All for Love* (1677).

Antonym, *AN tuh nihm,* is a word that has the opposite meaning of another word. For example, *fast* and *slow* are opposites and therefore antonyms.

Words that mean the same or approximately the same as one another are called *synonyms.* Many dictionaries follow the definition of a word with a list of synonyms. Sometimes, a list of antonyms follows the synonyms. A special dictionary called a *thesaurus* provides lists of synonyms and antonyms. Sara Garnes

Antwerp, *ANT wuhrp* (pop. 462,800), is Belgium's largest city and its main port. Antwerp is one of the major ports of Europe. It is called Antwerpen (pronounced *AHNT vehr puhn*) in Flemish and Anvers (pronounced *ahn VEHR*) in French.

Antwerp lies on the Schelde River, 55 miles (89 kilometers) from the North Sea (see **Belgium** [political map]). Its waterways and railways serve all Belgium and industrial cities in Germany and France.

Commerce and industry. The harbor at Antwerp is one of the world's largest. Besides its vast trade, the city has many industries, among which are sugar refining, lacemaking, brewing, distilling, and shipbuilding. It is the world's largest diamond-trading center.

Chief buildings. Among the buildings that have been preserved from the early period of Antwerp's greatness, the most important is the Cathedral of Notre Dame. The cathedral is the largest Gothic church in Belgium and often considered the most beautiful. Its graceful tower rises over 400 feet (120 meters) above the flat surrounding plain. The cathedral is famous for artistic treasures, including masterpieces of Peter Paul Rubens.

The town hall, of Renaissance architecture, was built in the 1500's. It contains many carvings, murals, and other works of art. Antwerp has a picture gallery with a

fine collection of Flemish paintings. The most famous are priceless works of Rubens and Van Dyck. The Plantin-Moretus, a museum, was the house and workshop of the great printer Plantin, and contains a historical collection about early printing. The home of Rubens, which is also a museum, contains many of the artist's paintings.

History. Antwerp began to attain prominence in the 1400's, when it became a great port of trade between the European mainland and England. During the 1500's, Antwerp was one of the world's richest cities and the chief money market of Europe. The first stock exchange was set up there in 1531. Antwerp reached the height of its prosperity about 1560, just before entering the struggle of the Netherlands to gain its freedom from Spain.

Antwerp declined steadily until 1800, when its population was below 40,000. Napoleon, realizing its strategic and commercial value, decided to open and improve its harbor and to set it up as a rival to London. He considered that Antwerp in the hands of a powerful enemy would be "a pistol held at the breast of England." The trade of Antwerp began to grow rapidly, but this lasted only until 1830. Then Belgium separated from Holland. The Dutch, who controlled the Schelde estuary upon which Antwerp is located, imposed heavy tolls upon shipping. These tolls were abolished in 1863, and Antwerp's trade at once began to grow.

Antwerp was for a long time the key fortress in the national defense of Belgium, and one of the strongest fortresses in Europe. But modern artillery enabled the Germans to capture and occupy Antwerp in World War I (1914-1918). In May 1940, during World War II, German troops occupied the city. They mined the harbor, planning to destroy the installations upon retreating. But daring Belgian underground workers prevented the explosions when the Allies liberated Antwerp in September 1944. The port helped Europe recover after the war.

Aristide R. Zolberg

Anubis, *uh NOO bihs,* was an important god of the underworld among the ancient Egyptians. His main center of worship was at Kynopolis, which means *Dog City* in Greek. Because the dog, or jackal, was his sacred animal, Anubis is often represented in the form of a crouching dog or jackal. His functions were associated with those of Osiris, the chief god of the underworld, and with those of Thoth, another of Osiris's assistants. It was Anubis's duty to attend to the ritual preparation of bodies, to weigh the heart of every person on the scale of justice, and to judge a person's good and bad deeds on earth. Anvers. See Antwerp.

Anxiety, *ang ZY uh tee,* is a term used by mental health professionals to mean the same as *fear* or *worry.* Sigmund Freud, the founder of psychoanalysis, showed that anxiety is a basic emotion that influences everyone's life from earliest childhood. This influence shapes the lives of people who are mentally healthy as well as those who are mentally ill.

Excessive anxiety is a factor in both mild and severe mental illness. People with psychological disorders may experience a disruptive amount of anxiety in response to many real or imagined circumstances. When people dread or avoid particular objects or activities, such as spiders, flying, or being in high places, these special dreads are called *phobias.* Nancy C. Andreasen

Anzio, *AN zee OH* or *AHN see OH* (pop. 33,497), is a small seaport and resort on the west coast of Italy (see Italy [political map]). In World War II, American troops landed at Anzio and set up a beachhead after heavy fighting in January 1944. Anthony James Joes

Aorta, *ay AWR tuh,* is the body's longest and largest artery. Its many branches distribute purified blood to all parts of the body. The first part of the aorta is the *ascending aorta.* It rises from the left ventricle of the heart almost to the top of the breastbone. The aorta's first branches are the coronary arteries, which supply blood to the heart. From near the top of the breastbone, the aorta arches backward and slightly to the left to form the *arch of the aorta.* Branches from the arch supply blood to the head and neck. The section after the arch, the *descending aorta,* passes downward through the chest and abdomen. It supplies the bones, organs, and muscles with blood. In the chest, or *thorax,* the aorta is called the *thoracic aorta;* in the abdomen, the *abdominal aorta.* At the hips, the aorta divides into two large arteries, the *common iliac arteries,* which carry blood to the pelvis and legs. Joseph V. Simone

Apache Indians, *uh PACH ee,* belong to any of about five tribes of the southwestern United States. According to the 2000 U.S. census, there are about 55,000 Apache. About 25,000 Apache live on reservations in Arizona and New Mexico. Apache tribes include the Jicarilla, the Mescalero, the San Carlos, and the White Mountain Apache. During the late 1800's, the Apache became known for their fierce resistance to U.S. government attempts to restrict them to reservations.

The Apache once hunted game and gathered wild plants for food. They wore animal skins and lived in thatched houses or in tepees. These Indians became known as warlike because of their raids against early Spanish settlers and other Indian tribes in the area.

The Apache were placed on reservations in the 1870's after being defeated by the United States Army. However, several Apache bands fled from their reservations and resumed their raids. In 1885, Geronimo led the most famous outbreak from an Apache reservation. He surrendered in 1886. The Army imprisoned many peaceful Apache along with Geronimo and his followers.

Today, many Apache work for tribal-owned lumber or cattle companies. The Jicarilla of New Mexico earn most of their income from mineral deposits on their reservations. In 1982, the Supreme Court of the United States upheld the right of the Jicarilla to tax the production of oil and natural gas on their lands. Keith H. Basso

Apartheid, *ah PAHRT hayt* or *ah PAHRT hyt,* was, from 1948 until 1991, the South African government's policy of rigid racial segregation. The word *apartheid* means *separateness* in Afrikaans, one of South Africa's official languages.

Built on earlier South African laws and customs, apartheid classified every South African by race as either (1) black, (2) white, (3) Colored (mixed race), or (4) Asian. Apartheid required segregation in housing, education, employment, public accommodations, and transportation. It segregated not only almost all whites from nonwhites but also major nonwhite groups from each other. It also limited the rights of nonwhites to own and occupy land, and to enter white neighborhoods.

The South African government tried to justify apartheid by claiming that peaceful coexistence of the races was possible only if the races were separated from one another. However, white South Africans used apartheid chiefly as a way to control the vast nonwhite majority.

Most South Africans strongly opposed apartheid. Leading opposition groups included the African National Congress (ANC). Most ANC members were blacks. Between 1948 and 1991, large numbers of people protested apartheid by staging boycotts, demonstrations, and strikes. Violence often broke out, and thousands of people, most of them blacks, were killed.

Many countries also opposed apartheid. As a result, South Africa grew increasingly isolated in the world community. In 1962, the United Nations General Assembly urged its members to break diplomatic and economic ties with South Africa until apartheid was abolished. During the 1980's, a widespread economic boycott of South Africa took hold. In response to domestic and international pressure, South Africa began repealing apartheid laws in the 1970's and 1980's. Finally, in 1991, the government repealed the last of the laws that formed the legal basis of apartheid.

But apartheid's effects continued even after the laws were repealed. Today, many blacks and other nonwhites continue to face unofficial segregation and discrimination in South Africa. Thomas F. Pettigrew

Apatosaurus, *uh PAT oh SAWR uhs* or *AP uh toh SAWR uhs,* was a giant, plant-eating dinosaur that lived about 150 million years ago in what is now the Western United States. It belonged to a group of huge, long-necked, long-tailed dinosaurs called *sauropods.*

Apatosaurus was about 70 feet (21 meters) long, stood about 15 feet (4.6 meters) high at the hips, and weighed about 33 tons (30 metric tons). It had long, thin teeth and may have eaten tree leaves and ferns. Its nostrils were on top of its relatively small, slender head. The neck was about 20 feet (6 meters) long. The animal's straight, thick legs ended in broad feet, and the inner toe of each foot had a blunt claw. The front legs were shorter than the hind legs, and so the body sloped down from the hips to the neck. The tail extended about 30 feet (9 meters) and ended in a slender point.

Apatosaurus is the official name for this dinosaur, but it is also known as *Brontosaurus.* The American scientist Othniel C. Marsh, a pioneer in *paleontology* (the study of prehistoric life), first discovered an incomplete skeleton of this dinosaur in 1877. He named it *Apatosaurus.* Two years later, scientists found a more complete skeleton, which Marsh mistakenly believed to be a new type of dinosaur. He named it *Brontosaurus,* meaning *thunder lizard,* because of the noise that such a large animal must have made when it walked. But scientists soon realized that these two dinosaurs were the same, and so the first name, *Apatosaurus,* became the formally accepted name. Peter Dodson

See also **Dinosaur** (picture: When dinosaurs lived).

Ape is a member of the group of animals that most closely resemble human beings. There are five main kinds of apes—bonobos, chimpanzees, gibbons, gorillas, and orangutans. All these animals have hairy, tailless bodies; longer arms than legs; and long fingers and toes. They also have large brains and rank as the most intelligent animals next to human beings.

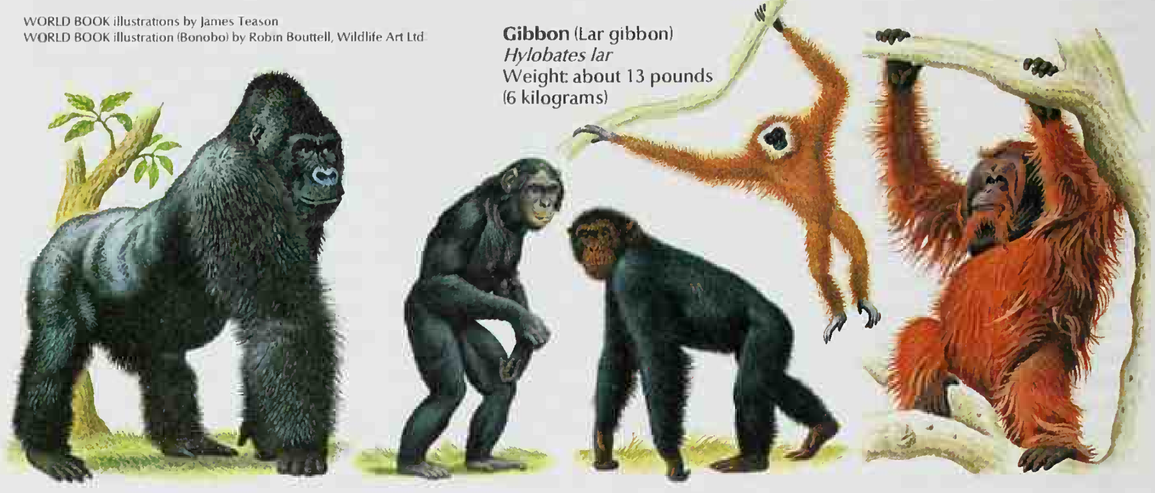
Most scientists believe apes and human beings developed from a common ancestor. Apes resemble humans in body structure more than any other animals do. For example, they have similar bones, muscles, and organs. But human beings also differ from apes in many ways. Humans walk on two legs and have longer legs and less body hair than apes. They also have a larger brain than apes. For more information on human beings and apes, see **Human being** (Physical characteristics).

Scientists divide the apes into two groups, based chiefly on size. Gibbons, the smallest apes, are called *lesser apes.* Bonobos, chimpanzees, gorillas, and orangutans are called *great apes.* Gorillas are the largest, followed by orangutans, chimpanzees, and bonobos.

Differences between apes and monkeys. Many people confuse apes with monkeys, but the two groups of animals differ in many ways. Most monkeys have tails and seem less intelligent. The great apes are much larger and have longer fingers and toes. Apes are skillful tree climbers. On the ground, bonobos, chimpanzees, and gorillas walk in a semiupright posture, supporting the front part of their bodies on their knuckles. Orangutans walk infrequently on the ground, but when they do they support themselves on their fists. Gibbons spend almost all their time in trees but often walk on two legs on branches. By contrast, monkeys run and jump on all fours, both in trees and on the ground.

Way of life. Apes live in tropical Africa and Asia. All apes except gorillas eat mostly fruit. Gorillas eat mainly ground plants, such as wild celery and bamboo shoots.

Gibbons live in the tropical forests of Southeast Asia. They spend much time hanging from tree branches or swinging from branch to branch. Gibbons form family groups of a male and a female and their young.



Chimpanzees live in a wide range of habitats throughout Africa. They are found in rain forests as well as dry grasslands, and live in trees and on the ground. Chimpanzee groups may vary from 10 to over 50 members. Often, the females leave their group and join another.

Bonobos, also called *pygmy chimpanzees,* resemble chimpanzees but are more slender. Bonobos inhabit a section of rain forest in Congo (Kinshasa). Like chimpanzees, they live both in trees and on the ground. Bonobo groups normally contain 7 to 10 individuals, including both males and females.

Gorillas live in the lowland forests of western and central Africa and in the mountain forests of eastern Africa. Large males often sleep on the ground, but females

The five types of apes There are five major kinds of apes: gorillas, bonobos, chimpanzees, gibbons, and orangutans. Gorillas, bonobos, chimpanzees, and orangutans are known as *great apes.* Gibbons, the smallest apes, are called *lesser apes.* These illustrations include average weight figures for adult males.

WORLD BOOK illustrations by James Teason

Gibbon (Lar gibbon)
Hylobates lar
Weight: about 13 pounds (6 kilograms)

Gorilla
Gorilla gorilla
Weight: about 450 pounds (204 kilograms)

Bonobo
Pan paniscus
Weight: about 100 pounds (45 kilograms)

Chimpanzee
Pan troglodytes
Weight: about 110 pounds (50 kilograms)

Orangutan
Pongo pygmaeus
Weight: about 180 pounds (82 kilograms)

and the young sleep in trees. Gorillas travel in groups of up to 20 individuals. Older males develop a patch of white or silvery hair on their backs and are called *silverbacks.* One of these males leads each group.

Orangutans live in the tropical forests of Borneo and Sumatra. They spend most of the time in trees, though large males are often seen on the ground. Orangutans usually travel alone, but a female and her offspring travel together.

The number of apes is decreasing because people hunt them for food and for pets and to sell to zoos and research centers. In addition, roads, farms, and the forest industry have destroyed much of the forests where apes once lived. Randall L. Susman

Scientific classification. Apes belong to the order Primates. The great apes make up the family Pongidae. Gibbons make up the family Hylobatidae. Bonobos and chimpanzees are in the genus *Pan,* gorillas are genus *Gorilla,* and orangutans are genus *Pongo.* Gibbons belong to the genus *Hylobates,* except for the *siamang,* which is genus *Symphalangus.*

See also Bonobo; Chimpanzee; Gibbon; Gorilla; Orangutan.

Apelles, *uh PEHL eez,* was one of the most famous ancient Greek painters. He lived during the 300's B.C. Although none of his paintings has survived, their subjects are known from ancient authors who praised the artist for the amazing realism of his work. Apelles was court painter to Philip II and Alexander the Great of Macedonia. Apelles painted a portrait of Philip and another of Alexander holding a thunderbolt. Apelles was also famous for his painting of the goddess Aphrodite rising from the sea. Marjorie S. Venit

Apennine Tunnel, *AP uh NYN,* is a train tunnel on the Florence-Bologna railroad line in north-central Italy. The tunnel runs through the mountain range called the Apennines. Its $11\frac{1}{2}$-mile (18.5-kilometer) length makes it one of the longest train tunnels in the world. The tunnel was built between 1920 and 1934. Herbert H. Einstein

Apennines, *AP uh NYNZ,* is a mountain range in Italy that extends from the Gulf of Genoa to the Strait of Messina, about 840 miles (1,350 kilometers). The range varies from about 25 to 80 miles (40 to 130 kilometers) in width. The mountains have been worn down by wind and rain for millions of years and are among the lowest in Europe. Corno Grande, the highest peak, rises 9,554 feet (2,912 meters). Vesuvius, a famous peak, is the only active volcano in mainland Europe. Many types of vegetation grow in the Apennines. Shrubs and rough pastures grow above about 6,000 feet (1,800 meters). Below them are forests of beech, chestnut, conifers, and oak. Olive groves and farms spread across the lowest elevations. The mountains consist mainly of limestone and marble. Quarries near Carrara are noted for their marble. See also Italy (The Apennines; terrain map). Howell C. Lloyd

Apgar, Virginia (1909-1974), was an American physician who developed a system for evaluating the physical condition of a baby immediately after birth. The system, known as the Apgar score, assigns a numerical score to five vital functions measured one and five minutes after birth. Doctors worldwide use the score to determine the short-term health care needs of newborn babies.

Apgar was born in Westfield, New Jersey. She studied zoology, chemistry, and physiology at Mount Holyoke College in Massachusetts, graduating in 1929. She studied medicine at Columbia University, receiving her M.D. in 1933. Apgar specialized in anesthesiology, a branch of medicine that deals with the administration of drugs for the relief of pain, especially during surgery. In 1938, she was appointed the first director of anesthesiology at Columbia-Presbyterian Medical Center in New York City. In 1949, she became the first female professor at Columbia's College of Physicians and Surgeons. That same

year, she began to study the use of anesthesia during childbirth. This research led to the development of the Apgar score, introduced in 1952.

In 1959, Apgar joined the National Foundation-March of Dimes (now the March of Dimes Birth Defects Foundation), where she helped raise public support and funds for research on birth defects. She coauthored *Is My Baby All Right?* (1972), which dealt with birth defects.

See also Apgar score.

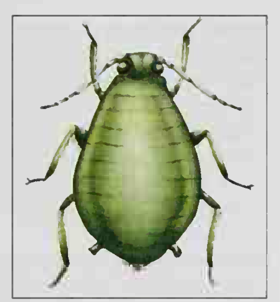
Apgar score is a system for evaluating the physical condition of a baby immediately after birth. An Apgar score is given to most babies born in the United States and to newborns in many other parts of the world. The score measures five vital functions: (1) appearance (skin color), (2) pulse (heart rate), (3) grimace (reflex response), (4) activity (muscle tone), and (5) respiration. The first letters of these functions form the word *Apgar.* The Apgar score is obtained at one minute and, in most cases, at five minutes after birth.

A newborn baby can score from a low value of 0 to a normal value of 2 for each function. The scores are then added, for a maximum total of 10. A baby who scores 7 or higher receives routine care. A score of less than 7 indicates that the baby may need emergency respiratory treatment to survive. In such cases, the five-minute score can demonstrate the success of the treatment. If the five-minute score remains below 7, the doctor may continue treatment and retest the baby every five minutes until a score of 7 or higher is obtained.

Doctors use the Apgar score with other measures of a newborn's condition to help predict the baby's short-term health prospects. The Apgar score was developed by the American physician Virginia Apgar and introduced in 1952. Gerald B. Merenstein

See also **Apgar, Virginia.**

Aphasia, *uh FAY zhuh,* is the loss or partial loss of the ability to use and understand spoken and written language. It results from damage to the language centers of the brain. Many cases result from a stroke, which occurs when part of the brain does not receive sufficient oxygen-carrying blood. Aphasia also may result from a brain tumor, an infection, or a blow to the head.



Aphasia may affect some types of communication more than others, depending on the site and extent of the brain injury. Most people with aphasia have difficulty reading, writing, speaking, and understanding words and sentences. Their ability to use numbers and gestures also may be impaired. Some types of aphasia may affect only reading or writing. People with such reading disabilities as *alexia* and *dyslexia* can see written material but cannot read it. People with *agraphia* cannot write even though their fingers and hands are undamaged.

Two speech disorders, *dysarthria* and *apraxia,* are often associated with aphasia. Dysarthria results from damage to the nerves that control the muscles used for speech, such as the tongue. In patients with this disorder, speech sounds are slurred. Patients with apraxia have forgotten how to make certain sounds though they may have normal use of the speech muscles.

Some aphasia patients can regain part or most of their ability to understand language. Working with speech-language pathologists can help most patients. But if no improvement occurs within several months, complete recovery is unlikely. Russell L. Malone

See also **Brain** (In the use of language).

Aphid, *AY fihd* or *AF ihd,* also called *plant louse,* is a tiny, soft-bodied insect that feeds on plant juices. Many kinds of aphids are harmful to gardens, orchards, and farm crops. They have plump bodies, small heads, and mouths shaped into tubes. They use the tubes to pierce plant stems or leaves and feed on the juices. Aphids may be green, black, whitish, or other colors. Many aphids have four wings. Others are wingless.

WORLD BOOK illustration by Shirley Hooper, Oxford Illustrators Limited

Aphid

Most kinds of aphids produce a sweet fluid called *honeydew.* This fluid is one of the favorite foods of the ant. The ant licks up the honeydew as it pours out of tube-shaped organs called *cornicles* at the tip of the aphid's body. In order to have plenty of honeydew, ants take good care of some kinds of aphids. They move the aphids from one plant to another and may infest an entire garden.

Aphids multiply very rapidly. The males and females mate in the fall. The females lay fertilized eggs that hatch the next spring. These young do not mate and lay eggs. They give birth to living young hatched from unfertilized eggs within their bodies. During summer, many generations of fatherless aphids are born by this process, called *parthenogenesis.* In fall, adult males and females appear, and the life process repeats. Spiders, ladybugs, and lacewings prey on aphids. Candace Martinson

Scientific classification. Aphids are in the order Hemiptera and the aphid family, Aphidae.

See also **Ant** (Dairying ants); **Mosaic disease; Phylloxera; Whitefly.**

Aphrodite, *AF roh DY tee,* was a major Greek goddess. She was the Greek version of an Asian goddess of life similar to Astarte. Many artists and poets have restricted Aphrodite's role to goddess of love and beauty, but her functions in ancient Greece were varied and complex. The Greeks worshiped Aphrodite as a universal goddess called Urania (queen of heaven) and as a goddess of civic life called Pandemos (goddess of all people). In some parts of Greece, Aphrodite was considered a goddess of seafaring and warfare. She was also associated with the myths and ceremonies surrounding Adonis, a fertility god who died and was reborn annually. Many myths report that she instigated human love affairs. The Roman goddess Venus was identified with Aphrodite.

In the works attributed to the Greek poet Homer, Aphrodite was the daughter of the goddess Dione and Zeus, the king of the gods. In earlier myths, Aphrodite rose full-grown from sea foam. The name *Aphrodite* may come from *aphros,* the Greek word for *foam.*

According to Homer, Aphrodite was married to Hephaestus, the blacksmith of the gods. But many stories give her other lovers, including Ares, the god of war, and the Trojan prince Anchises. In later myths, she was the mother of Eros, the god of love. F. Carter Philips

Apollinaire, *a paw lee NAIR,* **Guillaume,** *gee YOHM* (1880-1918), a French poet, was a leader in the arts in Paris during the decade before World War I (1914-1918). Apollinaire experimented with new literary techniques and crusaded for early abstract painting and for the Cubism movement in art.

Apollinaire was born in Rome. He traveled and read widely, and his work suggests many different times, places, legends, and people. He often used images of rootlessness along with a robust fantasy and a sense of wonder at the many discoveries of his time. While remaining highly individual, his poetry covers a wide range of styles and moods. The love poetry of his first major collection, *Alcools* (1913), is memorable for its delicacy and richness in expressing disappointment in love and sorrow at the passing of time. His second volume, *Calligrammes* (1918), published shortly before his sudden death, contains war poems and a number of highly original compositions. In some of them, words are arranged typographically as pictures.

Jean-Pierre Cauvin

Apollo, *uh PAHL oh,* was a major god in Greek mythology. He was the son of Zeus, the king of the gods, and the goddess Leto. The goddess Artemis was Apollo's twin.

Apollo probably originated in Asia Minor (now Turkey). At one time, he was known as a god of shepherds. Apollo also became associated with archery, healing, music, poetry, prophecy, purification, and seafaring. Under the name *Phoebus Apollo,* he became the god of light. He was also considered the god of the sun. Only Zeus was more widely worshiped than Apollo.

Apollo killed a dragon named Python at Delphi and established his temple there. The Greeks believed Apollo foretold the future through an *oracle* (prophet) at Delphi. Temple priests asked questions of this oracle, an elderly woman named the Pythia, who responded in the words of Apollo. The priests interpreted her responses. Delphi became the greatest of Apollo's many oracles throughout the ancient world. See Delphi; Oracle.

The Greeks sometimes blamed Apollo and Artemis for sudden deaths. They killed the children of Niobe, queen of Thebes, who had boasted that she had more children and was superior to Leto (see Niobe).

Apollo was unsuccessful in many of his love affairs. For example, he loved the nymph Daphne, but she fled from him. When Apollo was finally about to catch her, Daphne called out for help and was changed into a laurel tree (see Daphne). Apollo also loved Coronis, a mortal woman. But Coronis was unfaithful, and either Apollo or Artemis killed her and her lover.

The Romans worshiped Apollo primarily as a god of healing and prophecy. His influence increased when the Roman emperor Augustus made him his *patron* (protector). In art, Apollo is depicted as a beardless young man, the Greek ideal of male beauty. He is often shown with a bow or lyre.

F. Carter Philips

Apollo program. See Space exploration (Apollo: Mission to the moon; Other moon landings).

Aponte Martinez, *ah POHN tay mahr TEE nays,* **Luis Cardinal,** *loo EES* (1922-), archbishop of San Juan, became the first Puerto Rican cardinal of the Roman Catholic Church. Pope Paul VI appointed him a cardinal in 1973. Aponte Martinez was born in Lajas, Puerto Rico, and was ordained a priest in 1950. In 1960, he was ordained a bishop and became auxiliary bishop of Ponce, Puerto Rico. Aponte Martinez was named archbishop of San Juan in 1964.

Kenneth Guentert

Apostlebird, is a quick-moving, gray or black bird about 12 inches (30 centimeters) long. It is native to Australia, where it roams woodlands, eating insects and seeds. Apostlebirds travel in groups of about 12 and were named after the 12 Biblical apostles.

Bertin W. Anderson

Scientific classification. The apostlebird belongs to the family Grallinidae. Its scientific name is *Struthidea cinerea.*

Apostles, in the New Testament, are the 12 men chosen by Jesus Christ to be His close companions. The term is also used to identify other early missionaries, such as Paul and Barnabas. The word is used once in the Bible to refer to Jesus Himself. The term *apostle* should be distinguished from *disciple,* a New Testament term for any follower of Jesus.

There are four lists of the 12 apostles in the New Testament. The lists agree on Peter (also called Simon Peter), Andrew, James, John, Philip, Bartholomew, Thomas, Matthew, James the son of Alphaeus, Simon, and Judas Iscariot. The gospels of Matthew and Mark list Thaddeus, while the gospel of Luke and Acts of the Apostles list Judas the son of James (or the brother of James in some versions of the Bible). After Judas Iscariot killed himself for betraying Jesus, Matthias was chosen to take his place among the 12. This story, told in Acts 1: 21-26, states that an apostle must have accompanied Jesus from the time of Jesus's Baptism until His Ascension into heaven.

Richard A. Edwards

There is a separate article in *World Book* for each apostle. See also Acts of the Apostles; Barnabas; Jesus Christ; Paul, Saint.

Apostles' Creed is a statement of the main Western Christian beliefs. It contains three sections, dealing with God the Father, Jesus Christ, and the Holy Spirit. Both Roman Catholic and Protestant churches use it today. Here is the basic Catholic form of the Apostles' Creed:

> I believe in God, the Father Almighty, Creator of heaven and earth; and in Jesus Christ, His only Son, our Lord; who was conceived by the Holy Spirit, born of the Virgin Mary, suffered under Pontius Pilate, was crucified, died, and was buried. He descended into hell; the third day He rose again from the dead; He ascended into heaven; sits at the right hand of God, the Father Almighty; from thence He shall come to judge the living and the dead. I believe in the Holy Spirit, the holy Catholic Church, the communion of saints, the forgiveness of sins, the resurrection of the body, and life everlasting. Amen.

The Protestant form generally substitutes the word *Maker* for *Creator* and uses *catholic* or *Christian* instead of *Catholic*.

The earliest version of the Apostles' Creed can be traced back to the A.D. 100's. A legend arose stating that the creed was composed by the 12 apostles, but this has not been proven. It is more likely that the creed simply grew out of the life of the Christian church. The creed probably was derived from an earlier Roman Creed, which was a baptismal confession. Richard L. Schebera

Apothecaries' weight, *uh PAHTH uh KEHR eez,* is a system of weights once widely used by druggists for prescriptions. The metric system has replaced it. Apothecaries' weight divides the pound into 12 ounces, the ounce into 8 drams, the dram into 3 scruples, and the scruple into 20 grains. In the apothecaries' system, 5,760 grains make 1 pound (0.373 kilogram) and 480 grains make 1 ounce (31 grams). See also **Metric system; Ounce; Pound; Weights and measures.** Leland F. Webb

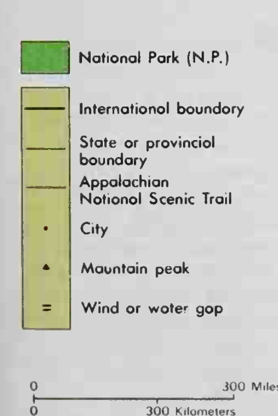
Apothecary. See Pharmacy.

Appalachian Mountains, *AP uh LAY chuhn* or *AP uh LACH uhn,* are the second largest mountain system of North America. Only the Rocky Mountain system is larger. The Appalachians extend about 1,500 miles (2,400 kilometers) between the Gaspé Peninsula in the Canadian province of Quebec and Birmingham, in central Alabama. The valleys of these mountains include important agricultural and recreational regions. The Appalachians are also a major source of mineral deposits.

The Appalachian Mountains were formed between about 435 million and 250 million years ago. The Appalachians are the oldest mountains in North America. The name *Appalachian* comes from the Apalachee Indians.

Physical features. The chief ranges of the northern Appalachians include the Notre Dame Mountains in Quebec, the White Mountains in New Hampshire, the Green Mountains in Vermont, and the Catskill Mountains in New York.

Southwest of the Hudson River, the Appalachians are divided into three main sections—the Blue Ridge, the Great Valley, and the Ridge-and-Valley Province. The Blue Ridge has most of the Appalachians' tallest mountains, including the tallest, Mount Mitchell. This peak rises 6,684 feet (2,037 meters) near Asheville, N.C.



North of Virginia, the Blue Ridge Mountains are separated into small sections by major valleys called *water gaps* and *wind gaps*. A water gap, such as the Delaware Water Gap in Pennsylvania and New Jersey, is a valley that has a river flowing through it. A wind gap is a dry valley. An example of a wind gap is the Cumberland Gap on the borders of Kentucky, Tennessee, and Virginia.

Immediately west of the Blue Ridge is the Great Valley, which extends from the Hudson River Valley to Alabama. The Great Valley includes the Cumberland, Lebanon, and Lehigh valleys in Pennsylvania; the Cumberland Valley in Maryland; the Shenandoah Valley and the Valley of Virginia in Virginia; the Valley of East Tennessee; and the Coosa River Valley in Alabama.

West of the Great Valley is the Ridge-and-Valley Province, which consists of long, sharp ridges separated by

Appalachian Mountains

The Appalachian system extends about 1,500 miles (2,400 kilometers) across eastern North America, between central Alabama and the Gaspé Peninsula in Canada. The region includes important agricultural and mining areas and offers many recreational opportunities.

WORLD BOOK map

narrow valleys. It is bordered on the west by the Cumberland and Allegheny mountains. North of central Virginia, the Alleghenies in the north and the Blue Ridge and Great Smoky mountains in the south make the Appalachians one of the great divides of North America. This region separates rivers that empty into the Atlantic Ocean from those flowing into the Gulf of Mexico.

Economic importance. Thousands of people in the Appalachians make their living in farming or mining. Farmers in the southern sections grow corn and tobacco and raise poultry. In the northern part of the Appalachians, the chief valley products are apples, barley, dairy foods, hay, potatoes, and wheat. Trees from the region, including hickories, maples, and oaks, are shipped to furniture makers in Hickory and High Point, N.C. Coal deposits cover about 50,000 square miles (130,000 square kilometers) in the Appalachians in Alabama, Kentucky, Pennsylvania, Virginia, and West Virginia.

Recreation and wildlife. Rivers, lakes, and state and national parks provide a wide range of recreational opportunities in the Appalachians. During the winter, skiers from many states come to the northern Appalachians. Throughout the summer and fall, hikers walk along the Appalachian National Scenic Trail, the nation's longest marked footpath. This trail extends about 2,000 miles (3,200 kilometers) between Mount Katahdin in Maine and Springer Mountain in Georgia.

Many large mammals, including bears, bobcats, and deer, live in the Appalachians. Smaller mammals, such as raccoons and skunks, and reptiles are also plentiful.

A type of pollution called *acid rain* threatens wildlife in the region. Appalachian soils and lakes are naturally highly acidic because of the kinds of vegetation and *bedrock* (solid rock beneath the soil) found there. This acidic environment has been compounded by rain carrying sulfuric and nitric acid, which can harm plants and fish. The region is more seriously affected by acid rain than any other area in North America.

History. The Appalachians were formed between about 435 million and 250 million years ago by a folding in the earth's crust. During the late 1700's, pioneers followed the Great Valley southward through the Appalachians to the Cumberland Gap and the Wilderness Road. Railroads began to transport settlers across the mountains in the 1840's. In 1933, Congress created the Tennessee Valley Authority (TVA) to control flooding and provide electric power to the southern Appalachians. The TVA has built dams and power plants and has planted forests to halt soil erosion.

Appalachian National Scenic Trail, *AP uh LAY chuhn* or *AP uh LACH uhn,* is a footpath that extends about 2,000 miles (3,200 kilometers) from Mt. Katahdin in Maine to Springer Mountain in Georgia. The trail passes through 14 states, 2 national parks, and 8 national forests. It follows the crests of the White and Green mountains and the Berkshires of New England, the Blue Ridge Mountains from Pennsylvania to North Carolina, and the Unakas and Great Smokies of North Carolina. The trail became a part of the National Park System in 1968.

Appaloosa. See Horse (Color types; picture).

Appeal is the transfer of a legal action to a higher, or superior, court for review. The court may review the decision of a lower, or inferior, court; a government board; or the officer of an administrative hearing. The *appellant* (person who appeals) seeks to have the decision of the board, officer, or lower court reversed or modified. Usually, a dissatisfied party to a suit must file a notice of appeal with the court within a specified time and show a reason why the appeal should be granted. The discovery of new evidence or of an error in the trial or hearing are reasons often given for seeking an appeal. But there is an absolute right of appeal in most criminal cases. Many states also provide for an automatic appeal in criminal cases where a death sentence has been imposed.

Every state has at least one court to which appeals may be taken from trial courts. The federal court system includes 13 Courts of Appeals to review cases tried in lower federal courts. In some cases, the Supreme Court of the United States considers and reverses cases decided by a Court of Appeals or by a state supreme court.

A party in a state court action cannot appeal directly to the U.S. Supreme Court. He or she can only ask that court for a writ of certiorari. A *writ of certiorari* is an order from a higher court to a lower court to send up the records of a case for review (see **Certiorari, Writ of**). The court can refuse such an "appeal" unless it feels there has been a violation of federal law or of the party's constitutional rights. Jack M. Kress

Appellate court. See **Court** (Trial and appellate courts); **Trial** (The criminal defendant's rights).

Appendicitis, *uh PEHN duh SY tihs,* is an inflammation of the *vermiform appendix* (see **Appendix**). It results from an infection caused by bacteria. The appendix becomes swollen and fills with pus. The pus may be walled off and form an abscess. Or the appendix may break, allowing the infection to spread to surrounding body organs. It may also cause *peritonitis,* an inflammation of the membrane that lines the abdominal cavity (see **Peritonitis**).

Symptoms. An attack of appendicitis usually begins with pain in the region of the navel. Then it moves to the right lower side of the abdomen. At first the pain is not constant—it comes and goes. But soon it becomes continuous, and soreness develops over the appendix region. The abdominal muscles tighten, and the patient becomes nauseated and usually has a fever. A blood count shows an increase in white blood cells.

Treatment. It is very important that no laxatives or purgatives, such as castor oil, be given to a person with appendicitis. Purgatives should never be given to a person with an abdominal disorder that might be appendicitis. Any such medicines may cause the appendix to rupture, spreading bacteria through the abdomen. The patient should remain quiet. A doctor should be called immediately. The usual treatment for acute appendicitis is surgical removal of the appendix, an operation known as an *appendectomy.* In mild cases, the inflam-

Appendix, in anatomy, is a structure attached to a larger or more important part. The term usually refers to the *vermiform* (wormlike) *appendix,* a slender, closed tube that extends from the *cecum,* the first part of the large intestine. The vermiform appendix lies in the lower right part of the abdomen in human beings. It is also found in the higher apes, some rodents, and various other animals. Rats and certain other rodents have a long appendix that functions in digestion. In human beings, it probably has no function. Some people believe that the appendix lost its function through evolution. When inflamed, it causes a disease known as appendicitis. See also Appendicitis. Laurence H. Beck

The appendix is a narrow tube that extends from the cecum of the large intestine. A normal appendix, *above,* resembles a worm. Infection of the appendix produces appendicitis, *right,* a condition in which the appendix becomes swollen and filled with pus.

Appian Way, *AP ee uhn,* was the first and most famous military highway built by the ancient Romans. It is still used today. It was named for Appius Claudius Caecus, a Roman official who began its construction in 312 B.C.

The road led 132 miles (212 kilometers) from Rome southeastward to Capua, linking Rome to some of its early conquests. It was extended 234 miles (377 kilometers) to Brundisium (now Brindisi) on Italy's southeast coast. Early Christians met in tombs and catacombs along the road. Arthur M. Eckstein

Apple is one of the most important fruits that grow on trees. It is also one of the most popular of all fruits. Since prehistoric times, people have enjoyed the delicious flavor of apples.

There are hundreds of varieties of apples. Their color ranges from various shades of red to green and yellow, and their flavor varies from tart to sweet. Apple trees belong to the rose family. Their beautiful white flowers open in spring and look like tiny roses.

Apple growers throughout the world produce about 2 billion bushels of the fruit annually. China leads the world in apple production. The United States ranks second, followed by France, Italy, and Turkey.

In the United States, apple growing is an important industry in several regions, especially the Pacific Northwest. Washington produces more apples than any other state. The nation's apple crop totals about 260 million bushels each year, with a wholesale value of more than $1 \frac{1}{4}$ billion.

In Canada, apples are the most important fruit crop. They are grown commercially in British Columbia, New Brunswick, Nova Scotia, Ontario, and Quebec. Canadian growers produce about 30 million bushels of apples yearly.

Over half the apples grown are eaten fresh. Apples also are baked into pies and many other dishes. Apples are used in making apple butter, apple juice, applesauce, and jelly and wine. Apple juice may be made into vinegar. Most apple products are canned or bottled, and others are dried or frozen.

Apples consist of about 85 percent water. They contain vitamins A and C, potassium, pectin, and fiber.

Through the ages, apples have appeared in legends, poems, and religious books. In the Swiss legend of William Tell, a tyrant arrests an archer but promises to free him if he shoots an apple off his son's head. Tell does

so and later kills the tyrant with another arrow. Many people believe an apple was the fruit that, according to the Bible, Adam and Eve ate in the Garden of Eden.

Varieties of apples

Although there are hundreds of kinds of apples, only a few varieties account for most of the apples grown commercially and in home gardens. For example, three varieties of apples—Delicious, Golden Delicious, and Granny Smith—make up about two-thirds of the apples produced in the United States. Two other varieties—McIntosh and Rome Beauty—also rank among the leading apples grown in the United States. McIntosh and Delicious apples are the chief varieties that are grown in Canada.

The many kinds of apples differ in color, texture, taste, and size, as shown in the table in this article. The color of the skin may be green, yellow, or various shades of red. The flesh of apples is cream-colored, white, or yellow. The texture of the fruit may be soft or firm, and the flavor is tart or sweet. Generally, sweet apples are eaten fresh, and tart varieties are used in making such products as apple butter, applesauce, and vinegar. Flavorful cider is made from a blend of several varieties.

There are also about 25 species of wild apples, 8 of which grow in the United States. Most wild apples are crab apples (see **Crab apple**).

Apple growers in other countries raise several varieties that are seldom cultivated in the United States. For example, the Cox's Orange Pippin is grown in Denmark, the Netherlands, and the United Kingdom. The Bramley is a favorite cooking apple in Britain.

Raising apples

The apple is a *pome*—that is, a fruit that has a fleshy outer layer and a paperlike core. The apple usually has 5 to 10 seeds. The core encloses the seeds. Pears are also pomes.

Apple trees may grow more than 40 feet (12 meters)

Varieties of apples There are hundreds of kinds of apples, and they differ in color, flavor, shape, size, and texture. Different varieties are also used for different purposes. For example, Delicious apples are usually eaten fresh, but Golden Delicious apples are used primarily for baking pies.

tall. Most apple trees do not grow well in areas with extremely cold winters or long, hot summers, but they thrive in regions with moderately cold winters. The fruit does not grow during the cold season, but the trees must have such a season in order to flourish. In late spring, white flowers bloom on apple trees. The flowers must be pollinated by insects. For this reason, some growers place hives of honey bees in their orchards while the trees blossom.

Seeds grow in the ovary of a pollinated flower, and the ovary and other parts of the flower develop into the fruit of the tree. Most varieties of apples ripen in 140 to 170 days after pollination.

Apple trees can bear fruit for as long as 100 years. But most of the apple trees grown in orchards are replaced every 12 to 20 years.

Planting and caring for apple trees. Most apple trees are grown from buds. The buds are cut from a healthy tree that has produced the kind of fruit desired. The buds are grafted to the *rootstocks.* A rootstock is a root or a root plus a stem (see **Grafting**). These trees will bear apples of the same variety as those of the tree from which the buds were cut. Apple growers use the rootstocks of trees selected for their resistance to pests and to cold temperatures. By choosing different rootstocks, growers can also vary the height of the tree from 3 to 30 feet (0.9 to 9 meters).

Apple trees in orchards are planted in rows from 10 to 30 feet (3 to 9 meters) apart. This spacing enables growers to spray the orchards and to harvest the fruit easily. Growers prune the trees to improve the quality and quantity of the fruit. A young apple tree starts to bear fruit in 3 to 5 years, depending on the rootstock, the variety, and other factors.

Pests and diseases. Apple trees may be attacked by many species of insects and many diseases. The codling moth, the most destructive enemy of the apple, lays its eggs on the leaves and on the fruits in spring. *Larvae* (caterpillars) hatch from the eggs and bore into the young apples. Growers fight codling moths by spraying the trees with insecticides during the period that the females lay their eggs.

The European red mite, another pest, damages apple leaves. The females lay their eggs on the bark of the trees during the fall, and the young mites hatch in spring just before the flowers bloom. The mites, which suck the sap from the leaves, can be controlled with insecticides. Apple growers also minimize damage from these pests by introducing other mites and insects that prey on European red mites but do not harm apple trees.

The apple maggot, an insect that attacks the fruit, can be killed by spraying apple trees with an insecticide about midsummer, when the adult maggots mature and begin to lay eggs. Two species of sucking insects, aphids and San Jose scales, also harm apple trees. See **Aphid; Apple maggot; San Jose scale.**

Varieties of apples

Cortland, a dark red apple with red stripes, is large and has flat ends. It tastes mildly acid to sweet and is tender and juicy. It is eaten fresh and used for cooking. Its white flesh makes it an excellent salad apple.

Delicious has a solid dark red color or is dark red with darker stripes. It is medium to large and has an oval shape with five knobs on the bottom. This sweet-tasting apple is firm, crisp, and juicy and is usually eaten fresh.

Empire is a dark red apple. It has crisp, juicy, slightly tart flesh and is eaten fresh.

Gala is a yellowish-orange to red apple. Its yellow to cream-colored flesh is crisp and sweet.

Golden Delicious has a golden-yellow skin and an oval shape. Its juicy, firm flesh has a sweet flavor. It ranges from medium to large and is a good all-purpose apple.

Granny Smith is a bright green apple. It ranges from medium to large and has an almost round shape. Its firm flesh tastes tart and is eaten fresh and used for cooking.

Jonathan is bright red, touched with yellow and green. This apple varies from small to medium and has a tart flavor and juicy, firm flesh. Its shape is round to oval, and it is eaten fresh and baked in pies.

McIntosh, a bright red apple, is medium sized and round or oval. It tastes mildly acid to sweet. It has tender flesh and is usually eaten fresh.

Rome Beauty is red with yellow or green markings. It is large and has a round to oval shape. The crisp, firm flesh has a mildly acid flavor. This apple is used for cooking, baking, and processing.

Stayman is dull red with darker red stripes. This apple varies from medium to large and has a roundish shape. Its firm flesh has a mildly acid flavor and is eaten fresh and used for processing.

Winesap is bright dark red and roundish. It ranges from small to medium and has a mildly acid flavor. Its flesh is firm and juicy and is eaten fresh and used for processing.

York Imperial is green or yellow with red stripes. This medium to large apple is round to oval and has a slightly lopsided appearance. Its firm flesh tastes mildly acid to sweet. It is used mainly for processing.

Leading apple-growing countries

Tons of apples grown in a year

China	21,580,000 tons (19,580,000 metric tons)
United States	5,390,000 tons (4,890,000 metric tons)
Turkey	2,700,000 tons (2,450,000 metric tons)
France	2,480,000 tons (2,250,000 metric tons)
Italy	2,230,000 tons (2,020,000 metric tons)
Germany	2,170,000 tons (1,970,000 metric tons)
Iran	2,160,000 tons (1,960,000 metric tons)
Poland	1,980,000 tons (1,800,000 metric tons)
Russia	1,530,000 tons (1,390,000 metric tons)
India	1,450,000 tons (1,320,000 metric tons)
Argentina	1,180,000 tons (1,070,000 metric tons)

Figures are for a three-year average, 1997-1999.
Source: Food and Agriculture Organization of the United Nations.

The most damaging disease that attacks apple trees is apple scab, which is caused by a fungus. It is most severe in humid areas. The fungus spends the winter on the ground in the dead leaves of the trees. In spring, rain releases spores from the fungus, and they infect the flowers, fruit, and leaves. Growers control apple scab by spraying the trees with fungicides.

Fire blight, a disease caused by bacteria, kills blossoms, leaves, and twigs and gives the trees a scorched appearance. Growers combat fire blight by pruning infected wood and by applying various sprays to the trees. Some growers also fight the disease by planting apple varieties that can resist the bacteria.

Harvesting and processing. Apple growers start to harvest their crop in late summer or early fall. The harvest dates vary according to the variety of apples. Apples are picked by hand.

In the United States, some newly harvested apples are soon sold fresh to consumers. However, about one-fourth of the annual crop is stored in cold rooms that have a controlled atmosphere. The fruit stays fresh in these rooms for up to 12 months, and so consumers can buy the apples the year around. More than 40 percent of the U.S. apple crop is processed, including apples that are canned, dried, or frozen.

Leading apple-growing states and provinces

Tons of apples produced in a year

Washington	2,884,000 tons (2,616,000 metric tons)
New York	563,000 tons (511,000 metric tons)
Michigan	509,000 tons (461,000 metric tons)
California	414,000 tons (376,000 metric tons)
Ontario	244,000 tons (221,000 metric tons)
Pennsylvania	231,000 tons (209,000 metric tons)
Virginia	164,000 tons (148,000 metric tons)
British Columbia	162,000 tons (147,000 metric tons)
North Carolina	96,000 tons (87,000 metric tons)
Quebec	91,000 tons (83,000 metric tons)

Figures are for a three-year average, 1998-2000.

History

Apples have been a favorite fruit of people for at least $2\frac{1}{2}$ million years. Archaeologists studying the ruins of Stone Age villages in Europe have found the charcoal remains of apples. By the 300's B.C., the ancient Greeks were growing several varieties of apples. The ancient Romans also cultivated the fruit. The Romans spread various kinds of apples throughout much of England and other parts of Europe during their numerous military conquests. The early American colonists brought both apple seeds and apple trees with them from England. The colonists dried their apples or used them in making cider, vinegar, and apple butter.

As the settlers moved westward across America, they took apple seeds and seedling trees with them. Some settlers found that Indians had already brought seeds from apple trees in the East and had planted them around their villages.

During the early 1800's, a pioneer apple planter named John Chapman distributed apple seeds and apple trees to settlers in Ohio and Indiana. He became known as Johnny Appleseed. See **Appleseed, Johnny**.

Through the years, American apple growers have developed new and improved varieties of the fruit. In addition, researchers have introduced new ways to preserve and use apples.

Grant Heilman

Apple harvesters stand on ladders to pick the fruit from high branches. The workers fill their bags with apples and empty the fruit into large bins. Tractors equipped with lifting devices take the full bins to trucks or warehouses and bring empty bins back to the orchards.

Scientific classification. Apples belong to the rose family, Rosaceae. The scientific name for the wild apple of Europe and Asia is *Malus pumila.* All cultivated apples belong to the species *Malus domestica.*

Apple butter is a spread for bread made by cooking apples to a thick, pasty consistency, and seasoning with spices. Sometimes cider is added.

Apple maggot is the wormlike *larva* (young) of the apple fly. Apple maggots sometimes do serious damage to apple crops. These insects are also called *railroad* worms because they make long, winding trails under the apple skin. Apple maggots are especially harmful in New England and northern New York.

The adult fly is a kind of fruit fly. It is slightly smaller than the common house fly and has wings marked with four black bands. Eight to ten days after appearing in midsummer, the female fly begins laying eggs just under the skin of apples. Sometimes as many as 15 eggs are laid in one apple. The maggots that hatch burrow through the flesh of the apple, leaving rusty streaks in it. After feeding from four to six weeks, the maggots drop to the ground and enter the soil. They change to the pupal stage there and stay all winter. They emerge the following summer as adult flies.

Scientists have discovered that apple maggots can be controlled by hanging sticky traps of yellow panels or red spheres in the apple orchard. Adult flies are attracted to the shape and color of these traps, and they become entangled and die in the special adhesive.

John R. Meyer

Scientific classification. The apple maggot belongs to the fruit fly family, Tephritidae or Trypetidae. Its scientific name is *Rhagoletis pomonella.*

See also Codling moth; Fruit fly.

Apple of Sodom is a spiny plant found near Jericho, a city in the Middle East. It is related to the tomato and bears yellow fruits that look like small apples. Writers in Biblical times called a plant that grew near the Dead Sea the apple of Sodom. They said it looked tempting but turned to bitter ashes in the mouth. Today, some people believe the ancients' story was a legend and was not about an actual fruit. Others think the writers referred to a plant different from the one bearing the name today. The term *apple of Sodom* is sometimes used to describe anything that looks pleasing but proves disappointing. William G. D'Arcy

Scientific classification. The apple of Sodom belongs to the nightshade family, Solanaceae. It is *Solanum linnaeanum* and was formerly *S. sodomeum.*

Appleseed, Johnny (1774-1845), was the name given to John Chapman, an American pioneer who planted large numbers of apple trees along the early frontier. He became a folk hero as the result of many novels, short stories, and poems about his deeds. However, most of

Engraving from *History of Ashland County, Ohio,* frontispiece, J. B. Lippincott & Co., Philadelphia; Chicago Historical Society

Johnny Appleseed was a pioneer planter.

these deeds were probably imaginary.

Chapman was born in Leominster, Massachusetts. Nothing is known about his childhood. From 1797 until his death, he traveled alone through Ohio and Indiana, planting orchards as the settlers moved westward. Chapman eventually owned about 1,200 acres (490 hectares) of orchards.

The most famous story about Chapman tells of his giving apple seeds and apple saplings to everybody he met. He supposedly traveled hundreds of miles to tend one of his orchards. Some people said Chapman wore a tin pot as a hat, a coffee sack as a shirt, and no shoes. Various tales describe him as a medicine man to the Indians.

None of the folk stories about Chapman has ever been proved true. The tales became widely known after an article describing his deeds appeared in *Harper's New Monthly Magazine* in 1871. The article, called "Johnny Appleseed, a Pioneer Hero," was written by an author named W. D. Haley. Harry Oster

Appleton, Sir Edward Victor (1892-1965), a British physicist, won the 1947 Nobel Prize in physics for his discovery of the *Appleton layer* in the ionosphere. This layer of free electrons, 143 miles (230 kilometers) high, reflects radio waves back to the earth. Appleton was born in Bradford, England. During World War II (1939-1945), he served in the United Kingdom's Department of Scientific and Industrial Research. In 1949, he became the principal and vice chancellor of the University of Edinburgh, in Scotland. See also Ionosphere.

Applied science. See Agriculture; Engineering; Medicine; Science; Technology.

Appliqué, *AP lih KAY,* is a decorative process used in sewing and dressmaking. It consists of sewing cut-out designed pieces of cloth onto a larger piece. The edges of the designed piece are usually tucked under. Then it is sewed onto the larger piece with small, hidden stitches or ornamental stitches. Patrick H. Ela

© Richard Nowitz, Corbis

Appliqué is a method of decorating objects by sewing cut-out pieces of such materials as cloth or leather onto a larger piece.

Appomattox Court House, *AP uh MAT uhks,* was a little country settlement in central Virginia. It was the scene of Robert E. Lee's surrender to Ulysses S. Grant on April 9, 1865, ending the Civil War. It became a National Historical Park in 1954. The park is near the town of Appomattox, Virginia. Among points of interest are the McLean House, site of the agreement on the surrender terms, a visitor center, and a Confederate cemetery. For the area of the park, see National Park System (table: National historical parks). See also Civil War (The South surrenders). Critically reviewed by the National Park Service

National Park Service

Appomattox Court House in Virginia was the site of Robert E. Lee's surrender to Ulysses S. Grant in 1865, ending the Civil War. The surrender took place in the McLean House, shown here.

Apportionment is the process by which representation in legislative bodies is distributed among the people. It may involve the assignment of a number of seats to specified areas, such as states or counties. Each area may then be divided into districts, from which representatives are elected. The reassignment of seats in a legislature among the areas represented is usually called *reapportionment.* The division of an area into new election districts is called *redistricting.* However, these terms are often used interchangeably to mean any change in an area's representation.

Representation has been apportioned in various ways. Two common bases have been (1) population and (2) political units, such as states, counties, or townships. In *bicameral* (two-house) legislatures, one house may be based on population and the other on political units. For example, in the United States Congress, each state still is allowed two senators regardless of population. States are apportioned seats in the House of Representatives according to population, with each state guaranteed at least one seat. Each state legislature draws up its state's congressional election districts.

Great differences in the population of districts occur when representation is not based on population. Differences may arise even when population is the apportionment base. As people move from rural areas to urban areas, some districts become more heavily populated than others. People in overpopulated districts have less influence in the legislature than people in underpopulated areas. But legislatures often do not redistrict because they wish to protect the seats of some members. In the United States as late as 1962, the population of many state legislative districts varied by as much as 30 to 1.

Initial efforts to get U.S. courts to order redistricting failed. The Supreme Court of the United States held that the issue was of a "political nature" and thus could not be decided by the courts. The Supreme Court reversed this ruling in the 1962 case of *Baker v. Carr.* In this case, the court held that voters could bring questions of unfair apportionment before federal courts. Since this ruling, legislatures have been undergoing a major redistricting upheaval. Based on 1963 and 1964 rulings, the Supreme Court developed the "one-person, one-vote" principle. As a result, all congressional districts must be "substantially equal" in population, and districts for electing both houses of state legislatures must meet the same requirement. The principle was extended to local governments in 1968. In 1969, the court demanded that the states try to make their congressional districts precisely equal in population. In 1973, the court clarified its position on state legislative districts. It ruled that the populations of these districts need not be exactly equal if the districts were drawn to reflect legitimate considerations, such as following political subdivisions or equalizing political opportunity. Robert Agranoff

See also Baker v. Carr; Gerrymander; House of Representatives (Size); Senate (Size); State government (Legislative branch).

Apposition extends the meaning of a word or phrase next to it. Words that are in apposition refer to each other. Most appositive units can be considered nonrestrictive clauses with the relative pronoun and the verb deleted. Appositive units may be classified as nouns, adjectives, or adverbs. "Abraham Lincoln, (who was) *the 16th President of the United States,* was assassinated" is a noun appositive. "The crowd, (which was) *anxious to escape danger,* began to panic" is classified as an adjective

appositive. "The man shouted loudly, (which was) *even frantically*, to calm the crowd" is an adverb appositive.

A few appositives, called *restrictive appositives*, are an inseparable part of the word to which they are joined. Examples include "Alexander *the Great*" and "Winnie-*the-Pooh*." William F. Irmscher

Appraisal is an opinion of value, usually the *market value* of a piece of property. Market value is the most probable price at which a property would be bought or sold by knowledgeable people. Specialists called *appraisers* make appraisals. They are trained by professional appraisal societies, and many colleges and universities offer courses in appraising.

Lending companies have real estate appraised before they grant a mortgage on it. Government agencies use appraisals to help determine assessments, property taxes, and the price at which they buy private property for public use. Many people have private property appraised before they buy it or sell it.

Appraisers consider several factors in arriving at their estimates. These include the sale price of similar property, reproduction cost less depreciation, and estimated future income from property use. Market prices usually provide the best estimate of market value. Property location often affects real estate value more than physical improvements made on property. John M. Clapp

Apprentice is a person who learns a trade by working under the guidance of a skilled master. Apprentices serve in construction, metalworking, printing, and other skilled trades. Many employers and unions jointly direct apprenticeship programs. Usually, apprentices must be high-school graduates. Most apprentices earn wages and work regular hours. People who finish apprenticeships become *journeyworkers*, also called *journeymen*.

Apprenticeship dates from ancient times. But it reached its most developed form between about A.D. 1000 and 1600, under European craft guilds. Apprentices served in almost every occupation, including medicine, painting, and brewing. Some girls were apprenticed to learn domestic skills, but most apprentices were boys. Ordinarily, a boy in his early teens went to live with a master, who taught him a craft and fed, housed, and clothed him. In return, the boy worked for the master about seven years. Once the training ended, the boy was a journeyman. He could sell his labor to any master.

Between the late 1700's and mid-1800's, apprenticeship changed greatly as power-driven machinery allowed unskilled workers to perform tasks of skilled hands, such as sewing and weaving. But new areas for apprenticeship opened, especially among machinists, electricians, and tool and die makers. Warren Van Tine

Apprenticeship and Training, Bureau of, is an agency of the Employment and Training Administration of the United States Department of Labor. It promotes and helps develop apprenticeship and training programs in industry and sets standards for employers in these programs.

The bureau works with states, industries, labor unions, vocational schools, and community planning groups in planning apprenticeship programs. To be registered by the bureau, a program must meet standards established by the secretary of labor. For example, it must include supervised work experience and classroom training and must be administered without discrimination. Apprentices must receive periodic wage increases and evaluations of their progress. Upon completion of a program, an apprentice must be recognized as a journeyworker. The bureau is authorized by the National Apprenticeship Act of 1937.

Apricot, *AY pruh kaht* or *AP ruh kaht*, is a golden, peachlike fruit with a pit. Apricots are smaller than peaches, and they have a smoother skin. Some have a reddish blush on one side. Fresh and dried apricots are eaten raw or are cooked to make jams, pies, and puddings. A liqueur is made from the *kernels* (seeds) found inside the pits. Most kernels are bitter, but some apricots have sweet kernels that can be eaten like almonds.

Apricot trees may grow as tall as 30 feet (9 meters). They grow best in dry and mild climates. The trees blossom in early spring, so fruit production is poor where spring frosts are common. Apricots are native to eastern Asia and were brought to North America from Europe. California is the chief U.S. producer of apricots. Utah and Washington are also important growers.

Most apricot trees are grown by grafting buds onto the roots of plum, peach, or apricot seedlings. When the trees reach 1 year of age, they are transplanted from the nursery to orchards. Apricot trees are pruned more heavily than most other trees that bear their fruit on *spurs* (short side shoots). Larger fruit is produced by *thinning* (removing) some fruit from the tree when the fruit is about 1 inch (2.5 centimeters) in diameter. Most apricots are harvested by hand, though some mechanical harvesting is done in California. Fenton E. Larsen

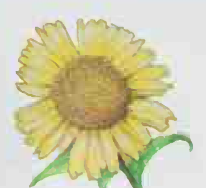
Scientific classification. Apricot trees are in the family Rosaceae. They are *Prunus armeniaca*.

WORLD BOOK illustration by Kate Lloyd-Jones, Linden Artists Ltd

The apricot is a golden fruit with a large pit. The apricot tree has delicate white or pink blossoms in the springtime.

April is the fourth month of the year, according to the Gregorian calendar, which is used by most of the world today. The Romans called the month *Aprilis.* This name might have come from a word meaning *to open,* or from the name of *Aphrodite,* the Greek goddess of love. April was the second month in an early Roman calendar. However, it became the fourth month when the ancient Romans moved the beginning of the year to January. On the first of April, April Fools' Day, people all over the world cause mischief and play tricks on each other.

Many cultures celebrate the arrival of spring, or other aspects of the natural world, in April. Walpurgis Night is a spring celebration held in Sweden and Finland on April 30. People there welcome spring with bonfires, singing, and parties. The Japanese hold Sakura Matsuri, the Cherry Blossom Festival, in April. In the Netherlands, flower parades are held toward the end of April, when the tulips are blooming. Many people plant trees on Arbor Day, which occurs on different dates in different countries. Many nations celebrate Earth Day on April 22. This holiday was organized in 1970 to raise awareness of the environment. The Angolan Feast of Nganja, a celebration of the corn harvest, has no specific date, but always falls in April.



Some cultures welcome the New Year in this month. Nava Varsha, the Nepalese New Year, falls on or near April 13. Several countries in Southeast Asia, including Cambodia, Laos, Myanmar, and Thailand, also celebrate the new year at this time. In Thailand, the holiday is called Songkran.

Chakri Day, April 6, marks the date in 1782 when King Rama I took control of Siam's (now Thailand's) govern-

Important April events

1 April Fools' Day in many countries.
— William Harvey, English physician, born 1578.
— Otto von Bismarck, Prussian statesman, born 1815.
— Edmond Rostand, French dramatist, born 1868.
— Sergei Rachmaninoff, Russian composer, born 1873.
2 Charlemagne, medieval European ruler, born 742.
— First federal U.S. mint established, 1792.
— Hans Christian Andersen, Danish fairy-tale writer, born 1805.
— Émile Zola, French novelist, born 1840.
— Walter P. Chrysler, American automaker, born 1875.
3 Washington Irving, American author, born 1783.
— John Burroughs, American naturalist, born 1837.
— First pony express service began in United States, 1860.
4 National Day, Senegal.
— Dorothea Lynde Dix, American prison and asylum reformer, born 1802.
— United States Congress adopted the flag with 13 stripes and with 1 star for each state, 1818.
— Robert E. Sherwood, American playwright, born 1896.
— North Atlantic Treaty signed, 1949.
5 Pocahontas married John Rolfe, 1614.
— Sir Joseph Lister, English surgeon, born 1827.
— Algernon Swinburne, English poet, born 1837.
— Booker T. Washington, American educator, born 1856.
6 Chakri Day, Thailand.
— Joseph Smith founded the Church of Jesus Christ of Latter-day Saints, 1830.
— Robert Peary, American explorer, reached what he claimed was the North Pole, 1909.
— United States declared war on Germany, World War I, 1917.
7 William Wordsworth, English poet, born 1770.
8 Hana Matsuri (Flower Festival) in Japan celebrates the birth of the Buddha.
— Henry Aaron broke Babe Ruth's career major-league home run record, 1974.
9 Isambard Kingdom Brunel, British engineer, born 1806.
— General Robert E. Lee surrendered to General Ulysses S. Grant in the American Civil War, 1865.
— Charles P. Steinmetz, German American physicist and electrical engineer, born 1865.
— Bataan Peninsula in the Philippines fell to Japan, 1942.
10 King James I chartered the Virginia companies of London and Plymouth, 1606.
— United States patent system established, 1790.
— Matthew C. Perry, American officer who opened Japan to world trade, born 1794.
— William Booth, English reformer and founder of the Salvation Army, born 1829.
— Joseph Pulitzer, Hungarian American publisher, born 1847.
— Clare Boothe Luce, American diplomat and playwright, born 1903.
11 Napoleon Bonaparte abdicated for the first time, 1814.
— Charles Evans Hughes, U.S. chief justice, born 1862.
12 Henry Clay, American statesman, born 1777.
— The American Civil War began at Fort Sumter, 1861.
— U.S. President Franklin D. Roosevelt died, 1945.
— Yuri Gagarin, Soviet astronaut, became the first person to orbit the earth, 1961.
13 The Edict of Nantes gave religious toleration to Huguenots in France, 1598.
— Thomas Jefferson, third U.S. president, born 1743.
— F. W. Woolworth, American merchant, born 1852.
— Samuel Beckett, Irish playwright, born 1906.
14 Christiaan Huygens, Dutch physicist, born 1629.
— Noah Webster copyrighted the first edition of his dictionary, 1828.
— John Wilkes Booth shot U.S. President Abraham Lincoln, 1865.
15 Leonardo da Vinci, Italian artist and scientist, born 1452.
— American Revolutionary War declared over, 1783.

April birthstone—diamond

April flower—daisy

April 5—Booker T. Washington born

April 6—Robert E. Peary reaches what he claims to be North Pole

ment. Matatirtha Aunsi, Nepalese Mothers' Day, also falls in April. The Christian celebration of Easter often occurs in this month, as does the Jewish festival of Pesah, also known as Passover.

April's flowers are the daisy and the sweet pea. The birthstone for April is the diamond. Carole S. Angell

Quotations

April cold with dropping rain
Willows and lilacs brings again,
The whistle of returning birds
And trumpet-lowing of the herds.
Ralph Waldo Emerson

When proud-pied April, dressed in all his trim
Has put a spirit of youth in everything.
William Shakespeare

The first of April, some do say
Is set apart for All Fools' Day;
But why the people call it so
Nor I, nor they themselves, do know.
From *Poor Robin's Almanac, 1760*

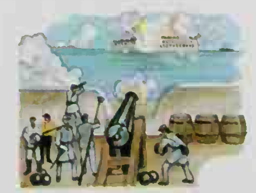
			Spring

April Fools' Day, or All Fools' Day, is the first day of April. In many countries, including the United States, it is the custom on this day to play tricks on people. A favorite joke is to send someone on a *fool's errand,* a search for something that does not exist. In the United States, the victim is called an *April Fool.*



Important April events

15 Henry James, American novelist, born 1843.
— Thomas Hart Benton, American painter, born 1889.
— British ocean liner *Titanic* struck iceberg and sank, 1912.
16 Anatole France, French novelist, born 1844.
— Wilbur Wright, American inventor, born 1867.
17 Independence Day, Syria.
— Samuel Chase, American jurist, born 1741.
— J. P. Morgan, American financier, born 1837.
— Nikita Khrushchev, Soviet premier, born 1894.
— Queen Elizabeth II signed Constitution Act, making Canada completely independent of the United Kingdom, 1982.
18 Independence Day, Zimbabwe.
— Famous ride of Paul Revere, American patriot, 1775.
— San Francisco earthquake and fire began, 1906.
— Lieutenant Colonel James Doolittle led carrier-based planes in a raid on Tokyo in World War II, 1942.
19 Independence Day, Venezuela.
— The American Revolution began, 1775.
20 Adolf Hitler, dictator of Germany, born 1889.
21 Rome founded, according to tradition, 753 B.C.
— Friedrich Fröbel, German founder of the kindergarten system, born 1782.
— Charlotte Brontë, English novelist, born 1816.
— Hippolyte Taine, French historian and critic, born 1828.
— Texans routed the Mexicans in Battle of San Jacinto, 1836.
— The Spanish-American War began, 1898.
— Queen Elizabeth II of the United Kingdom born in 1926.
22 Earth Day celebrated in many countries.
— Isabella I, Spanish queen and patron of Columbus, born 1451.
— Henry Fielding, English novelist, born 1707.
— Immanuel Kant, German philosopher, born 1724.
— V. I. Lenin, first dictator of the Soviet Union, born 1870. (April 10 on the Russian calendar then in use).
— Sidney Nolan, Australian artist, born 1917.
23 Traditional birth date of William Shakespeare, 1564.
23 James Buchanan, 15th U.S. president, born 1791.
— Sergei Prokofiev, Russian composer, born 1891.
— First public showing of a motion picture, in New York City, 1896.
— Lester Pearson, Canadian Prime Minister, born 1897.
24 American Library of Congress established, 1800.
25 William I, Prince of Orange, born 1533.
— Oliver Cromwell, English general, born 1599.
— Guglielmo Marconi, Italian inventor, born 1874.
— San Francisco Conference to establish the United Nations began, 1945.
26 Union Day, Tanzania.
— John James Audubon, American ornithologist and painter, born 1785.
— Alfred Krupp, German industrialist, born 1812.
27 Sierra Leone became independent in 1961.
— Togo became independent in 1960.
— Edward Gibbon, British historian, born 1737.
— Samuel Morse, inventor of the telegraph, born 1791.
— Ulysses S. Grant, 18th U.S. president, born 1822.
28 James Monroe, fifth U.S. president, born 1758.
— Maryland ratified the U.S. Constitution, 1788.
— Mutiny on the British ship *Bounty*, 1789.
— Charles Sturt, British explorer of Australia, born 1795.
29 Lorado Taft, American sculptor, born 1860.
— William Randolph Hearst, American publisher, born 1863.
— Sir Thomas Beecham, British conductor, born 1879.
30 Washington inaugurated as first U.S. president, 1789.
— Louisiana Territory purchased from France by U.S., 1803 (treaty was signed May 2, but dated April 30).
— Louisiana became the 18th U.S. state, 1812.
— Television first publicly broadcast, from the Empire State Building in New York City, 1939.
— Adolf Hitler committed suicide, 1945.
— Vietnam War ended, 1975.
31 Walpurgis Night (Feast of Valborg), Sweden.

April 18—Paul Revere's famous ride

No one knows where the April Fools' custom began. But some historians believe it may have started in France. There, the old New Year's festival was observed from March 25 to April 1 and ended with an exchange of gifts. In the mid-1560's, King Charles IX changed the New Year to January 1. People who still celebrated the New Year in April were called *April fish* and sent mock presents. April Fools' Day may be related to the ancient Roman spring festival Hilaria, which celebrates the resurrection of the god Attis. Jack Santino

Apuleius, *AP yuh LEE uhs,* **Lucius,** *LOO shuhs* (A.D. 125?-170?), wrote the only completely preserved novel in ancient Latin, *Metamorphoses,* also called *The Golden Ass.* This 11-part work is written in an elaborate, flowery style. It describes the adventures of a young man named Lucius who is accidentally turned into a donkey. He wanders about, observing how silly and cruel people can be. Lucius eventually is restored to human form by the Egyptian goddess Isis. The novel includes several short stories, of which the most famous is the tale of Cupid and Psyche (see **Psyche**). Apuleius was born in northern Africa. His other surviving writings deal with magic, oratory, and philosophy. Anthony A. Barrett

Aqua regia, *AK wuh REE jee uh,* is a mixture of nitric and hydrochloric acids. It is important in metallurgy and chemistry because it dissolves such metals as platinum and gold. *Aqua regia* is a Latin term meaning *royal water.* The mixture was given this name because it can dissolve gold, sometimes called the *royal metal.*

Aqua regia is made up of one part concentrated nitric acid to three parts of concentrated hydrochloric acid. Neither of these acids alone can dissolve gold or platinum. However, the chemical action between the acids forms nitrosyl chloride ($NOCl$) and chlorine gas, both powerful oxidizing agents. The presence of these oxidizers, plus excess hydrochloric acid, enables aqua regia to dissolve gold and platinum. Emily Jane Rose

Aquaculture, *AK wuh KUHL chuhr,* is the controlled raising of aquatic animals and plants. The primary goal of the aquaculture industry is to produce food. Aquaculture provides about a fourth of the seafood eaten in the world. In addition, some plants grown through aquaculture yield substances that are used as thickeners or gelling agents in foods, drugs, and other products.

Aquaculture takes place in natural bodies of water, in enclosures built on land, or in artificial ponds or reservoirs. In natural bodies of water, the crop may be grown in nets or cages, attached to rafts, or seeded on the bottom. The animals or plants may be raised in fresh, *brackish* (slightly salty), or salt water. By controlling environment, nutrition, breeding, and life cycle, aquaculturists can improve the quality and productivity of their crops.

Fish account for more than 50 percent of the annual worldwide aquaculture production. Seaweeds account for about 25 percent. Mollusks—mainly oysters, mussels, and clams—make up about 15 percent. Crustaceans—mainly shrimp and prawns—account for about 5 percent of aquaculture production.

Aquaculture is an ancient occupation. Chinese people practiced aquaculture between 3,500 and 4,000 years ago. Today, China still ranks as the world leader in raising aquatic plants and animals. It accounts for about 60 percent of the world's production.

The aquaculture industry expanded rapidly during the 1980's and 1990's. Worldwide production more than doubled from 1985 to 1995. Production in the United States nearly doubled during the same period. Many people expect aquaculture to continue to increase in importance as a source of food and other products for the world's rapidly growing population. Henry S. Parker

Aquamarine, *AK wuh muh REEN,* is a light blue or bluish-green variety of a gemstone called *beryl.* The most popular color is a clear sky-blue. Aquamarines are often treated with heat or radiation to improve their color. Almost all aquamarines are transparent. These stones are cut in *facets* (polished flat surfaces) and used in all types of jewelry. The aquamarine and the bloodstone are the two birthstones for March. Aquamarines have been known since ancient times. The ancient Romans believed the gem could cure laziness and produce courage. The most important source of aquamarines is Brazil. The gem is also found in Argentina, China, India, Madagascar, Myanmar, Namibia, Northern Ireland, Norway, Russia, and the United States. Pansy D. Kraus

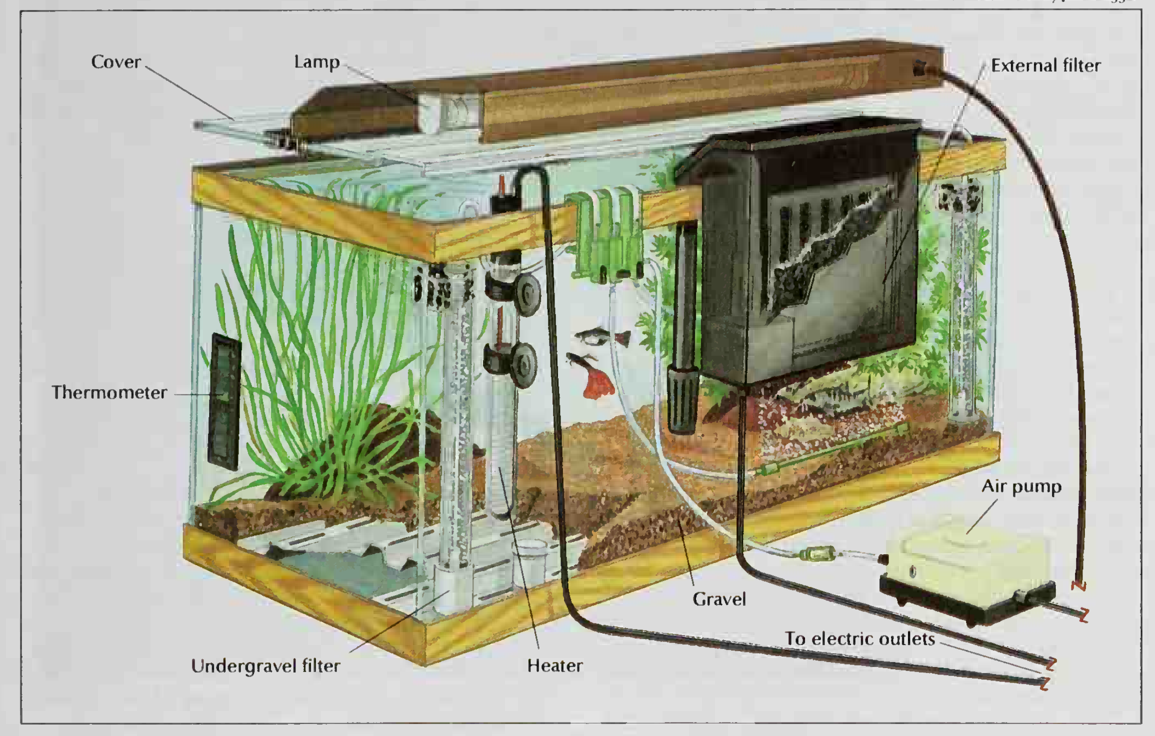
Aquarium, Home, is a place where people keep their collections of fish and other water animals. Most such aquariums are in people's homes, but some individuals have aquariums at work or other locations. The word *aquarium* also refers to large institutions that maintain extensive exhibits of fish and other creatures. For information on these places, see **Aquarium, Public.**

A person who has an aquarium is called an *aquarist.* Most home aquarists have freshwater aquariums rather than marine aquariums. The freshwater type requires less expense and work to set up and maintain.

Basic equipment for a home aquarium includes (1) a tank and tank cover, (2) one or more filters, (3) a heater, and (4) a thermometer.



A rectangular tank that holds 10 to 20 gallons (38 to 76 liters) is good for a beginning aquarist. Most aquariums are made of glass and are held together with silicone sealant to make them watertight. A decorative plastic strip covers the top and bottom edges. Most tank covers include an incandescent or fluorescent lamp that shines into the tank. Such covers, called *light reflectors,* make it easy to see the fish. Lids that cover the entire top prevent fish from jumping out of the tank and reduce the amount of heat loss.

The aquarium filter removes dirt suspended in the water and keeps the water clean. Some filters are connected to an electrically operated air pump. The pump produces a stream of air that pushes water through the filter. An aquarium may have an *external filter,* an *undergravel filter,* or both. External filters pump the water through activated carbon, filter pads, or filter floss, which remove particles and some impurities. Undergravel filters suck potentially harmful wastes into the gravel at the bottom of the tank. Bacteria in the gravel use the wastes as food and convert them into less harmful substances.

The electric heater warms the water to the proper

A home aquarium should have an air pump and one or more filters to keep the water clean. A heater keeps the water at the desired temperature, and a cover reduces the amount of heat lost. Plants and gravel help make the aquarium more attractive and provide a healthier environment for the fish.

WORLD BOOK illustration by John F. Eggert

temperature to keep fish healthy. For most fish, the water must be kept between 72 and 80 °F (22 and 27 °C). Most heaters hang on the tank's edge and extend into the water. Place the thermometer away from the heater where you can easily read it.

Setting up an aquarium. After acquiring a new tank, wash the tank inside and out with lukewarm, salty water and rinse it thoroughly. Place the tank on a level, strong surface near an electrical outlet. The aquarium should sit away from direct sunlight, drafts, and radiators. If only an external filter is used, the gravel should be rinsed and put into the tank in a layer about 1 inch (2.5 centimeters) deep. An undergravel filter should be covered with 2 to 3 inches (5 to 7.6 centimeters) of gravel.

Use tap water in your aquarium tank. Be sure to fill the tank a little at a time and to watch for leaks. When the tank is about two-thirds full, put in plants that can root in the gravel. Put the filter and heater in just before the aquarium is completely filled.

In most cases, the water should become suitable for fish two to three days after you fill the tank and start the electrical equipment. The water will look cloudy at first due to unsettled particles of dirt. Bubbles of gas may also appear. The cloudiness and bubbles will disappear in a day or two. After that time, a new cloudiness might appear, caused by bacteria. This condition should clear up in a few days.

Choosing fish and plants. Beginners should choose hardy, inexpensive fish that do not tend to fight or chase other fish. Popular fish for beginners include angelfish, cardinal tetras, guppies, mollies, neon tetras, and platies. Place only a few fish in the tank at first. You may add more fish gradually over several weeks. The aquarist must be careful not to put too many fish in the tank. The total length of all the fish in inches should be no greater than the number of gallons in the tank.

Most aquarists begin with fish that give birth to fully formed young that are able to swim. These fish, called *live-bearers,* include guppies and platies. Most female live-bearers will produce young about every six weeks when the water is kept at about 75 °F (24 °C).

A live-bearer about to give birth has a bulging belly and a dark spot on the bottom of her body. Keep the *fry* (young fish) separate until they get big enough to live among adult fish without being eaten.

Some kinds of fish, called *egglayers,* hatch their young from eggs. Good egglayers for beginners include cardinal tetras, neon tetras, white clouds, and small angelfish. To breed, a female egglayer swollen with eggs should live in a separate tank with a male. Babies of egglayers are harder to raise than those of live-bearers. Live-bearers and egglayers can live in the same tank.

Plants make the aquarium more attractive and provide some food and shelter for the fish. They also give off oxygen, which the fish breathe, and take in carbon dioxide given off by the fish. Good aquarium plants include *Elodea,* which can be stuck in the gravel or floated on the surface; and *Vallisneria,* which takes root in the gravel. Many aquarists use lifelike plastic plants, further reducing tank maintenance.

Keeping the fish healthy. Most aquarium fish should eat once or twice a day. At each feeding, fish should get no more than they can consume in 10 minutes. Most tropical fish will eat any good-quality commercial fish food. They also may have live and processed brine shrimp, shellfish called *Daphnia,* and red worms called *Tubifex.* Some fish can find particles of food overlooked by others, and so help clean the tank. These fish include catfish and algae eaters.

Many fish diseases can spread quickly and kill all the fish in an aquarium. Signs of illness include change of color, funguslike growths, poor appetite, slow or unusual movement, and spots. If any of these signs appear, place the affected fish into a separate tank. A tropical fish dealer can provide information on treatment.

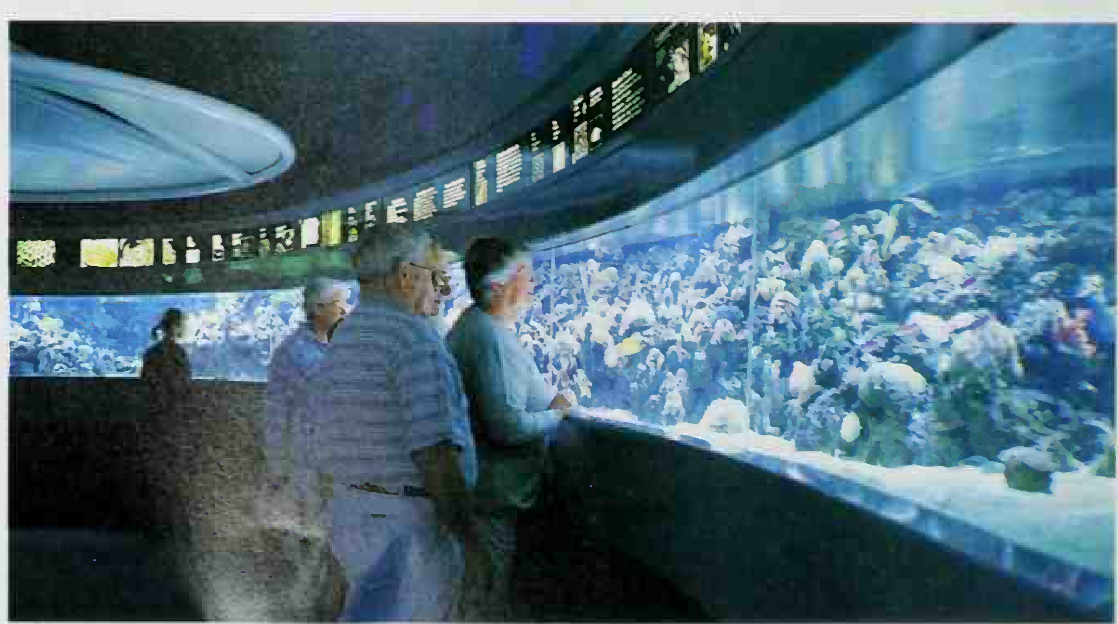
Do not place new fish in the aquarium water until they have adjusted to the water's temperature. To help the fish adjust, float the plastic bag containing the new fish in the aquarium for 15 minutes, adding a small amount of aquarium water to the bag every 5 minutes. Some aquarists keep new fish in a separate tank for several days to check them for disease. Louis E. Garibaldi

See also **Goldfish; Tropical fish.**

Aquarium, Public, or *aquatic zoo,* is an institution where people keep and display fish and other animals that live in water. Some public aquariums are parts of zoos, but most are independent institutions. Aquariums called *oceanariums* primarily display large *marine* (saltwater) mammals, including dolphins, seals, and whales. Other aquariums combine a traditional aquarium with an oceanarium. Such institutions may have large indoor and outdoor exhibits.

The word *aquarium* also refers to small collections of aquatic life that people keep in their homes. For information on these aquariums, see **Aquarium, Home.**

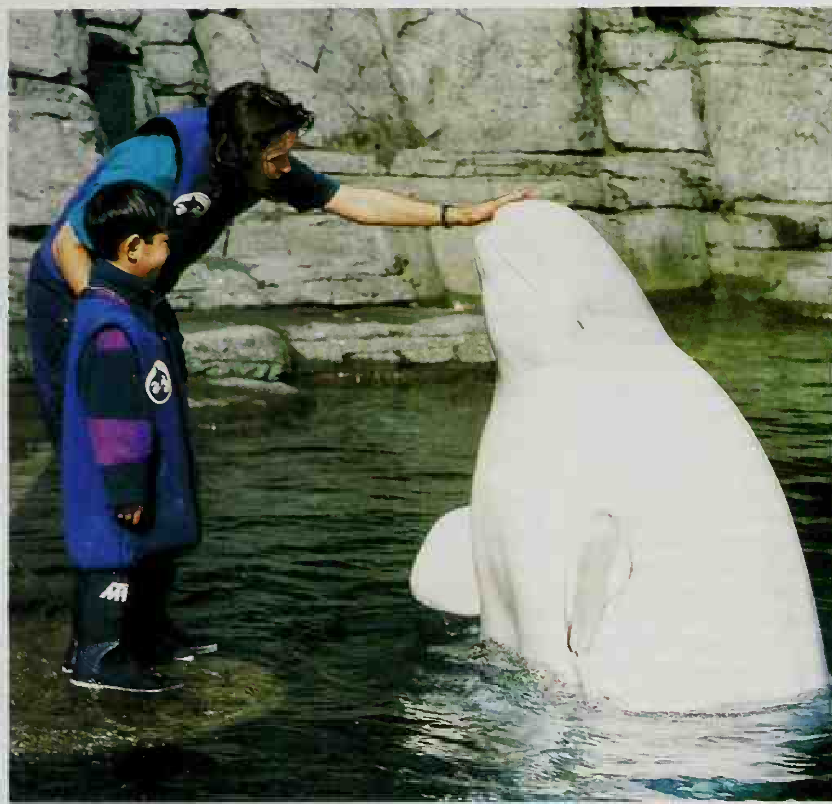
The purpose of aquariums



Public aquariums serve many purposes. They include recreation, education, research, and conservation.

Recreation. People enjoy seeing live aquatic animals. The animals' interesting behavior and unusual appearance attract millions of visitors to aquariums each year. Aquariums use huge tanks with *acrylic* (plastic) viewing windows to showcase large underwater habitats. These exhibits let visitors observe many underwater creatures they might otherwise never see. Aquariums may also present popular shows featuring seals, dolphins, and other trained marine mammals.

Education. Aquarium visitors learn many interesting facts about aquatic life from viewing the exhibits, which usually display information about the animals. Students take school field trips to aquariums to learn more about the animals they study in class. Most aquariums provide tours and lectures for schoolchildren and other groups.



Research. Creating the appropriate environment for each aquarium animal requires extensive research on that animal's habitat and way of life. Much of our knowledge of the lives of aquatic animals comes from such research. For example, biologists have learned most of what they know about the pregnancy of certain whale species by studying the animals in aquariums. Aquariums also have advanced the practice of *aquaculture* (the raising of aquatic life for food and other uses) by studying the diets and diseases of food fish and shellfish.

Conservation. Aquariums help conserve threatened aquatic animals in many ways. For example, they may raise populations of threatened species whose natural habitats have been damaged. Such animals include a species of steelhead trout from central California. Water levels in the Carmel River, the trout's native habitat, peri-

odically become very low because the river is heavily used as a human water source. To protect this trout from extinction, the Monterey Bay Aquarium continually collects the fish's eggs from the river and raises the fish to maturity. When the river's water level is high enough, aquarium workers release the captive-raised trout back into their natural habitat. Such activities keep river populations of the fish high enough to ensure their survival.

Aquariums also help raise visitor awareness of conservation issues. For example, whale and dolphin shows have long informed visitors about the declining numbers of marine mammals. Increased awareness of this issue has led to the passage of government legislation protecting marine mammals and their habitats.

How aquariums operate

Obtaining animals. Aquariums often rely on their own breeding programs to provide them with many of their exhibit animals. To expand the range of their collections, however, aquariums must purchase animals from outside sources. Public aquariums buy many of their exhibit animals from the suppliers that sell aquatic life to fish markets and pet shops. Aquariums also exchange animals among one another. On occasion, aquariums acquire specimens from individual fish collectors, or they may collect species directly from nature. Public aquariums must obtain permits to acquire and display threatened species, or species considered harmful to local water habitats.

Displaying exhibits. Aquarium exhibits range from small 10-gallon (38-liter) glass tanks to huge habitat exhibits in excess of 2 million gallons (7.6 million liters). Public aquariums display different animals for different reasons. Some creatures, such as blind cavefish, represent animals that have developed specialized adaptations for unusual habitats. Others, including lobsters and groupers, represent animals that provide people with important sources of food.

Aquarium exhibits place together animals that live together in nature. Most exhibits attempt to re-create particular environments, such as coral reefs, rocky shores, or tide pools. Aquarium workers add rocks, plants, and other features of an environment to each exhibit. These additions help satisfy the animals' ecological needs. They also make the exhibits more realistic for viewers.

Most large public aquariums display habitats from around the world. Smaller, regional ones often emphasize environments from their own local waters. Many aquariums use one or more tanks to present short-run exhibits, which last 12 to 18 months. These presentations focus on one region, such as Mexico's Gulf of California, or on a group of animals, such as sharks or sea horses.

A number of aquariums have created presentations called *immersion experiences* that give visitors an unusual perspective of aquatic environments. For example, certain aquariums take guests through shark-inhabited tanks on moving sidewalks in acrylic tunnels.

Caring for animals involves many tasks. They include feeding, maintaining clean tank environments through life support systems, and providing medical care.

Feeding. Aquarium animals require a variety of specialized diets. Most aquarium inhabitants will eat a

wide range of frozen natural foods, such as fish, shrimp, and squid. But many species will consume only live animals. Aquariums raise and maintain a number of live foods, including algae, crabs, and small bait fish.

Life support systems. An aquarium's exhibit tank must always have clean water processed through life support systems. These systems maintain a safe environment for the animals. They circulate the water, remove particles of dirt and animal waste, eliminate dissolved poisonous materials, and maintain high levels of dissolved oxygen for animals to breathe. Life support systems also keep the water at an appropriate and stable temperature.

Medical care. Nearly all aquariums employ a veterinarian to help care for their animals. When a new animal arrives, the aquarium at first keeps it quarantined from the rest of the collection. During quarantine, aquarium workers clean the animal of parasites and check for diseases. Daily observations of the animals help identify medical problems that may require treatment.

Jobs. Many aquarium jobs require a college degree, experience working with animals, or both. These aquarium professions include veterinarians, biologists and laboratory technicians who study the animals, aquarists who take care of exhibits, and trainers who work with animals in shows. Other aquarium employees help educate tour groups and maintain the life support systems.

History

Archaeological records indicate that the ancient Sumerians, in what is now Iraq, kept food fish in ponds over 4,500 years ago. About 2,000 years ago, ancient Romans kept both food fish and pet fish in shallow ponds and pools. The Chinese probably bred the first domestic goldfish more than 1,000 years ago. They displayed these fish in porcelain vessels.

During the mid-1800's, the invention of relatively clear glass tanks led to the development of modern aquariums. In 1853, the Zoological Society of London opened its "Fish House," the first true public aquarium, at its zoological gardens in London. The exhibition became so popular that other aquariums opened in cities across Europe over the next 20 years. The first true public aquarium in North America, the Boston Aquarial Gardens, opened in 1859 in Boston.

Marine Studios, later called Marineland of Florida, was founded near St. Augustine in 1938 for filming underwater motion-picture scenes. It soon became a popular tourist attraction and developed the trained animal show with dolphins and other sea mammals. Marineland's success led to the foundation of other similar theme parks, including the popular SeaWorld parks. Such places, in turn, helped promote the development of oceanariums.

During the late 1900's, aquariums became both more numerous and more controversial. The invention of large acrylic viewing panels in the 1970's enabled aquariums to showcase large aquatic habitats. Improved technology, along with the spread of oceanariums, greatly increased the popularity of aquariums. Some animal welfare groups, however, raised concerns about oceanariums. Such groups oppose keeping large sea mammals in captivity. They argue that aquarium environments are too restrictive for these creatures, whose natural habitats often cover large areas of the oceans. Despite such criticism, an unprecedented number of oceanariums and other aquariums were built worldwide in the late 1900's and early 2000's.

Aquarius, *uh KWAIR ee uhs,* is the 11th sign of the zodiac. It is symbolized by a person carrying a pitcher of water. Astrologers believe that Aquarius is ruled by two planets—Saturn, which they consider a stern planet; and Uranus, the planet of change and disturbance. Aquarius is an air sign. Astrologers believe that people born under the sign, from January 20 to February 18, show the influence of Saturn by being serious-minded. However, their independence and love of freedom reflect the influence of Uranus. Aquarians do not respect tradition and enjoy shocking people by their behavior.

Aquarians have powerful, logical, and scientific minds. They are always open to new ideas. Aquarians have many friends but are hard to get to know deeply. They usually avoid close personal relationships. Aquarians support social and political causes with great enthusiasm.

Christopher McIntosh

Aquatic plant. See Water plant.

Aqueduct, *AK wuh duhkt,* is an artificial channel through which water is conducted to the place where it is used. The materials used for aqueduct construction may be masonry, concrete, cast iron, steel, or wood. Some aqueducts are tunnels dug through rocks, and others are canals in the earth. In many aqueducts, the outlet is so much lower than the water source that gravity alone carries the water. Where gravity is insufficient, the water is forced through the aqueduct by pumps.

As cities and industries grow, they require more

water, and more aqueducts must be built. Such modern conveniences as commercial air conditioners require large quantities of water. Aqueducts also supply water to dry lands that must be irrigated to produce crops.

Ancient aqueducts. It is not known when or where the first aqueducts were built. In ancient times, Jerusalem used a leaky aqueduct made of a series of limestone blocks in which 15-inch (38-centimeter) holes had been drilled by hand. The Greeks built masonry conduits to bring water to their cities, and even bored tunnels by hand. One of these tunnels, 4,200 feet (1,280 meters) long, was built by Athens 2,500 years ago. Most aqueducts of ancient times were built of stone, brick, or *pozzuolana,* a mixture of limestone and volcanic dust.

The city of Rome had many aqueducts and was the only ancient city reasonably supplied with water. The first person in charge of the Roman waterworks was Marcus Agrippa, who was appointed water commissioner in 33 B.C. By A.D. 97, nine aqueducts brought about 85 million gallons (322 million liters) of water a day from mountain springs. Later, five additional aqueducts were built. About 200 cities in the Roman colonies had aqueducts. One famous Roman aqueduct, the Pont du Gard, still stands across a river near Nîmes, France.

Later aqueducts. Only a few new aqueducts were built until the Middle Ages. Late in the 1500's, an aqueduct was built for the English town of Plymouth by Sir Francis Drake, then mayor. It was called the *River Leet,* and was an open channel 24 miles (39 kilometers) long. London had no aqueduct until 1609 when the aqueduct called *New River* was built, bringing water 38 miles (61 kilometers) to London.

Present-day aqueducts. Costly bridges to carry water across rivers and valleys are no longer necessary. They have been replaced by pipe through which water is carried across hilly country. Sections of pipe called *inverted siphons* curve downward to pass beneath streams and other low places in the aqueduct's course.

One of the first great modern aqueducts was the first Croton Aqueduct, built by New York City in 1842. It was made of masonry lined with brick. Iron pipes carried water across the Harlem River over a viaduct. During the late 1800's, other cities, especially those of Britain, built large aqueducts. These cities included Birmingham, Glasgow, Liverpool, and Manchester.

Many of the world's greatest aqueducts were built in the early 1900's. The Catskill Aqueduct, completed in 1913 for New York City, extends 120 miles (193 kilometers). The Colorado Aqueduct, in southern California, was completed in 1939. It carries water through 29 tunnels across the desert from the Colorado River.

In 1973, a 685-mile (1,102-kilometer) aqueduct was completed in California. Other noted aqueducts in the United States include the Hetch-Hetchy (O'Shaughnessy), which supplies San Francisco, and those of Denver, Boston, and Tulsa. One of the most noted aqueducts is the Apulian Aqueduct of southern Italy. Other major aqueducts include those of Winnipeg, Canada, and Rio de Janeiro, Brazil. Larry W. Mays

Aqueous humor. See **Eye** (The uveal tract).

Aquinas, *uh KWY nuhs,* **Saint Thomas** (1225?-1274), was one of the greatest medieval philosophers and theologians. Through the centuries, he has influenced Christian—especially Roman Catholic—thought.

His life. Thomas was born of a noble family in Roccasecca, Italy, near Cassino. He attended the University of Naples from 1239 until 1244, when he joined the Dominican order. He was ordained a priest in 1250. From 1245 to 1252, he studied philosophy and theology under the German theologian Saint Albertus Magnus. In 1256, Thomas was named professor of theology at the University of Paris. There, he became famous because he developed his intellectual talents in the service of the Christian faith.

In 1258, Thomas began to write the *Summa contra Gentiles.* In this work, he tried to convince non-Christians that the doctrines of Christianity were not contrary to reason. From 1259 to 1268, Thomas wrote commentaries on many writings of the ancient Greek philosopher Aristotle. In 1265, he began to write his most famous work, *Summa Theologica,* in which he tried to systematically explain Christian theology. But Thomas had a mystical experience in 1273 that caused him to stop writing. He said that all he had written seemed like straw compared with what he had seen in this experience. Thomas' feast day is January 28.

His thought. Thomas combined Aristotle's teachings with Christian doctrine. For example, Thomas argued that no conflict exists between reason and faith. Philosophy is based on reason, he declared, and theology comes from faith in divine revelation, yet both come from God. So Thomas believed that any differences between divine revelation and the conclusions of philosophy result from faulty reasoning. He also maintained that reason can support faith. Thomas accepted—on faith—the idea that God exists. However, he formulated five proofs of His existence to support such a belief.

According to Thomas, all people desire happiness, but they can satisfy this desire only through direct communion with God. He believed that God gives grace to help human beings overcome the influence of sin and achieve this communion. Thomas taught that the sacraments are important in communicating God's grace to people.

Thomas believed that governments have a moral responsibility to serve people and to help them lead virtuous lives. He declared that governments must not violate what he considered human rights—life, education, religion, and reproduction. Thomas also taught that—to be just—laws passed by human beings must not contradict divine law. David B. Burrell

Aquino, *uh KEE noh,* **Corazon,** *KAWR uh ZOHN* (1933-), was the first woman president of the Philippines. She held the office from 1986 to 1992. Aquino succeeded Ferdinand E. Marcos. Both Aquino and Marcos claimed victory in an election marked by fraud and violence. But Marcos fled abroad when large numbers of Filipinos backed military officers who demanded his resignation. Aquino then became president. She did not run for reelection in 1992.

Aquino was born in Manila into a wealthy and politically influential family named Cojuangco. She studied in the United States and graduated from the College of Mount St. Vincent in New York City in 1953. In 1954, she married Benigno S. Aquino, Jr., who later became

the chief political rival of Ferdinand Marcos. Benigno Aquino was assassinated in 1983, and Corazon Aquino blamed the Marcos government for the murder. In November 1985, Marcos called for a presidential election, and Aquino rallied opposition to end his 20-year rule.

The Philippines experienced economic growth after Aquino became president. However, her critics charged her government with corruption and mismanagement.

Henry S. Bradsher

Arab-Israeli conflict is a struggle between the Jewish state of Israel and the Arabs of the Middle East. About 90 percent of all Arabs are Muslims. The conflict has included several wars between Israel and certain Arab countries that have opposed Israel's existence. Israel was formed in 1948. The conflict has also involved a struggle by Palestinian Arabs to establish their own country in some or all of the land occupied by Israel.

The Arab-Israeli conflict is the continuation of an Arab-Jewish struggle that began in the early 1900's for control of Palestine. Palestine today consists of Israel and the areas known as the Gaza Strip and the West Bank. The Palestinians lived in the region long before Jews began moving there in large numbers in the late 1800's.

The Arab-Israeli conflict has been hard to resolve. In 1979, Egypt became the first Arab country to sign a peace treaty with Israel. Jordan, another Arab country, signed a peace treaty with Israel in 1994. But Israel has not made final peace agreements with Syria or with the Palestine Liberation Organization (PLO). The PLO is a political body that represents the Palestinian people.

Historical background. In the mid-1800's, Jewish intellectuals in Europe began to support the idea that Jews should settle in Palestine, which the Bible describes as the Jews' ancient homeland. The word *Palestine* does not appear in the Bible. But it has long been used to refer to the area the Bible describes. The idea that Jews should settle in Palestine became known as Zionism. In the 1800's, Palestine was controlled by the Ottoman Empire, which was centered in present-day Turkey.

Zionism became an important political movement among Jews in Europe because of increasing *anti-Semitism* (prejudice against Jews) there. The anti-Semitism resulted in violent attacks on Jews and their property. In the 1800's, the immigration of European Jews to Palestine accelerated. At first, many of the immigrants and the Palestinian Arabs lived together peacefully. But as more Jews arrived, conflicts increased.

Israel and its Arab neighbors lie at the eastern end of the Mediterranean Sea. Arab countries that have fought wars against Israel include Egypt, Iraq, Jordan, and Syria.

After World War I ended in 1918, the United Kingdom gained control of Palestine from the Ottoman Empire. In the Balfour Declaration of 1917, the United Kingdom had supported creating a national homeland for the Jews. Under British rule, the Jewish population of Palestine continued to grow.

During World War II (1939-1945), German dictator Adolf Hitler tried to kill all of Europe's Jews. Thus, about 6 million Jews were murdered. After the war, most of the countries that defeated Germany supported the idea of creating a new Jewish state where Jews would be safe from persecution.

The 1948 war. In November 1947, the United Nations (UN) approved a plan to divide Palestine into two states, one Jewish and the other Palestinian. Zionist leaders accepted the plan. But Arab governments and the Palestinians saw the division as the theft of Arab land by Zionists and the governments that supported them.

British rule over Palestine ended when Zionists proclaimed the state of Israel on May 14, 1948. The next day, armies of Egypt, Syria, Lebanon, Transjordan (which became known as Jordan in 1949), and Iraq attacked Israel. Israel fought back. In the war, Israel absorbed much of the land the UN had set aside for the Palestinians. Egypt and Jordan occupied the rest of the area that was assigned to the Palestinians. Egypt held the Gaza Strip, a small area between Israel and the Mediterranean Sea. Jordan held the West Bank, a territory between Israel and the Jordan River. By August 1949, Israel and all five Arab states had agreed to end the fighting. Because of the war, about 700,000 Palestinians became refugees. Most fled to Jordan—including the West Bank—or to the Gaza Strip. Others went to Lebanon and Syria.

The Suez crisis of 1956. During the 1950's, nationalism spread among the Arab countries of the Middle East. Egyptian President Gamal Abdel Nasser and his followers sought to rid Arab lands of the influence of Western nations. On July 26, 1956, Nasser took control of the Suez Canal from its British and French owners. The canal connects the Mediterranean and Red seas and is a key shipping route between Europe and Asia.

Many countries protested Nasser's action. France, Israel, and the United Kingdom secretly plotted to end Egypt's control of the canal. On October 29, Israel attacked Egyptian forces in Egypt's Sinai Peninsula and quickly defeated them. The Sinai lies between Israel and the canal. Israel, with British and French help, occupied most of the peninsula. The UN called a cease-fire on November 6. By early 1957, Israel, under international pressure, returned the Sinai to Egypt. The canal reopened under Egyptian management in April of that year.

After the Suez crisis, Arab guerrillas launched small-scale attacks inside Israel, and Israel responded with raids into Arab territory. At the same time, the Arab nationalist movement began receiving financial and military support from the Soviet Union. The United States, fearing the spread of Soviet-sponsored Communism, gave financial and military aid to Israel.

In 1964, the PLO was formed to represent the Palestin-

ians. It included guerrilla groups dedicated to defeating Israel and creating an independent Palestinian state.

The 1967 war. In May 1967, Nasser closed the Gulf of Aqaba to Israeli shipping. The gulf was Israel's only access to the Red Sea. By June 5, Egypt had signed defense agreements with Syria, Jordan, and Iraq, creating a joint military command.

These apparent preparations for war alarmed the Israelis. On June 5, they launched a surprise attack on Egypt. Syria, Jordan, and Iraq joined Egypt in fighting Israel. Within hours, Israeli warplanes destroyed almost all the Arab air forces. Israeli tanks then retook the Sinai Peninsula. Israel also gained control of the West Bank, the Gaza Strip, and East Jerusalem. It had taken West Jerusalem in the 1948 war. In the north, Israel took Syria's Golan Heights, an area bordering Israel. The fighting ended on June 10. Israelis call this conflict the Six-Day War. Arabs call it the June War. After the war, Israel decided it would return the territories it had taken only if the Arab countries recognized its right to exist.

Also after the 1967 war, the PLO sought to become the representative of the Palestinians in world politics. It developed educational and social service organizations for Palestinians, mainly in the West Bank and Gaza Strip and in refugee camps in Lebanon and Jordan.

The PLO also began to take independent military action. In the late 1960's, PLO groups began to attack Israelis both inside and outside Israel. In response, Israel attacked Palestinian refugee camps in Jordan and Lebanon, in which many guerrillas were based. The Israelis also assassinated a number of PLO leaders.

The 1973 war. After the 1967 war, Egyptian and Israeli troops continued to attack each other across the western border of the Sinai Peninsula. On Oct. 6, 1973, Egypt and Syria launched a massive assault on Israeli forces in the Sinai Peninsula and Golan Heights. The attack took Israel by surprise, in part because it came on Yom Kippur, the holiest day in Judaism.

At first, Egypt drove Israel's forces out of the western Sinai, and Syria pushed Israeli troops from the eastern Golan Heights. However, the United States gave Israel large amounts of military equipment. By October 24, Israeli forces crossed the Suez Canal and surrounded the Egyptian army. They also defeated the Syrian army in the Golan Heights. Israelis call this war the Yom Kippur War. Arabs call it the October War or the Ramadan War.

The Camp David Accords. In 1978, Egyptian President Anwar el-Sadat joined Israeli Prime Minister Menachem Begin and U.S. President Jimmy Carter in signing the Camp David Accords. Under these agreements, Egypt recognized Israel's right to exist. In return, Israel agreed to give back to Egypt the part of the Sinai it still occupied. Israel had returned the far western part of the Sinai in 1975. In talks leading up to the accords, Egypt and Israel were promised large amounts of U.S. economic and military aid. In 1979, Egypt and Israel signed a treaty that confirmed their new peaceful relationship.

Most Arab leaders strongly opposed the Camp David Accords and the 1979 treaty. The Arab League, an organization of Arab countries, expelled Egypt in 1979.

The Israeli invasion of Lebanon. After the signing of the Camp David Accords, the PLO continued to launch guerrilla attacks on Israel, especially from southern Lebanon. In 1982, Israel invaded Lebanon and drove the PLO out of the southern part of the country. Israeli forces remained in southern Lebanon until 2000.

The first intifada. In 1987, Palestinians in the West Bank and Gaza Strip began an uprising against Israel's military rule of those territories. During this *intifada* (an Arabic term meaning *uprising* or *shaking off*), demonstrations occurred throughout the occupied territories. Most demonstrations were peaceful, but a few became violent. The intifada grabbed international attention and triggered criticism of Israel for its extensive use of force in trying to control the Palestinians.

Peacemaking. In 1988, the PLO recognized Israel's right to exist. It also declared its readiness to negotiate with Israel for peace in return for the creation of an independent Palestinian state. In addition, it declared it would no longer use violence against Israel. But some PLO members continued to attack Israeli targets.

In 1993, Israel and the PLO, aided by Norway, began secret peace talks. As a result, the PLO and Israel signed an agreement in Washington, D.C., in September 1993. Under the agreement, the PLO again stated its recognition of Israel's right to exist. Israel, in turn, recognized the PLO as the representative of the Palestinian people. It also promised to withdraw from part or all of the West Bank and Gaza Strip and to consider allowing the creation of a Palestinian state in those lands. In 1994, Israel gave the PLO control of the Gaza Strip and the West Bank city of Jericho. In 1995 and 1996, Israel gave the Palestinians control of most West Bank cities and towns.

Jordan signed a peace treaty with Israel in 1994. Peace discussions between Israel and Syria, however, broke down in 1996. Talks resumed in December 1999 but stopped the next month because of continuing disagreement over the Golan Heights.

AP Wide World

The 1967 war was one of several fought between Arab countries and Israel. In this photograph, an Israeli guard watches over Jordanian prisoners shortly after the 1967 war ended.

The second intifada. Peace talks between Israeli and Palestinian leaders continued in 2000. However, the two sides were unable to agree on key remaining issues, especially those involving the final status of Jerusalem. In September 2000, Palestinians began a second intifada against Israeli security forces. Numerous attacks by Palestinian militias and suicide bombers took place throughout Israel, the West Bank, and the Gaza Strip, killing hundreds of Israelis. Israeli forces repeatedly bombed and invaded the West Bank and Gaza Strip, killing more than 1,700 Palestinians. In 2002, Israel reoccupied much of the West Bank. William B. Vogele

Arab League is an organization of 21 Middle Eastern and African nations and the Palestine Liberation Organization (PLO). The PLO is an organization of Palestinian Arabs (see **Palestine Liberation Organization**). The Arab League's purpose, as stated in the Pact of the League of Arab States, is to promote closer political, economic, cultural, and social relations among the members.

A council composed of representatives of the member states works to settle disputes peacefully. It can also decide by unanimous vote how to repel aggression against a member. League activities are carried out by five major committees: (1) political, (2) economic, (3) social and cultural, (4) legal, and (5) Palestinian affairs.

The league was created in 1945, with seven Arab countries—Iraq, Saudi Arabia, the Lebanese Republic, Yemen (Sanaa), Transjordan (now Jordan), Egypt, and Syria. Since then, 16 other members have joined—Libya (1953), Sudan (1956), Morocco (1958), Tunisia (1958), Kuwait (1961), Algeria (1962), Yemen (Aden, 1968), Bahrain (1971), Oman (1971), Qatar (1971), United Arab Emirates (1971), Mauritania (1973), Somalia (1974), the PLO (1976), Djibouti (1977), and Comoros (1993). In 1990, Yemen (Aden) and Yemen (Sanaa) united as Yemen.

Generally, the league has not lived up to the aspirations of its founders. Mutual suspicions and rivalries among the members have made its political and defense agreements largely ineffective. The league has achieved some success in coordinating Arab opposition to Israel and in expressing the rights of the Palestinians. But its greatest accomplishments have probably occurred in the social, cultural, and communications fields. The formation in 1976 of ARABSAT, an Arab communications satellite system, is an example of the league's influence in fostering cooperation among Arab countries.

The league has often reflected rather than settled disputes among its members. In 1979, Egypt reversed its policy of hostility toward Israel, and the two nations signed a peace treaty. The league then suspended Egypt's membership and transferred its headquarters from Cairo to Tunis, Tunisia. Egypt was readmitted to the league in 1989. In 1990, most league members voted to move the headquarters back to Cairo.

The league became divided over an invasion of Kuwait by Iraq in August 1990. A majority of its members voted for a proposal to send Arab troops to join foreign forces defending Saudi Arabia from a possible attack by Iraq. But other members opposed the proposal and the presence of foreign troops. Michael C. Hudson

Arabesque, *ar uh BEHSK,* is a term used to describe the lacy surface decoration common in Islamic art. It is also used to mean any fanciful ornamentation composed of intertwined lines, leafy vines, and scrolls.

Arabesque design prominently features curving foliage patterns. These patterns may incorporate fruits, flowers, and leaves or such geometric shapes as circles, stars, and octagons. The Islamic religion forbids the portrayal of human or animal figures. Famous arabesque decoration appears in the walls and arches of the Alhambra (1248-1354), a palace and fortress in Granada, Spain. Arabesque became popular in Europe during the Renaissance and appeared on such objects as bookbindings, pottery, silver, and textiles. John W. Keefe

Arabia. See **Arabian Peninsula; Saudi Arabia.**

Arabian Desert, *uh RAY bee uhn,* is a desert that covers most of the Arabian Peninsula. It occupies about 1 million square miles (2.6 million square kilometers). Countries entirely in the desert are Saudi Arabia, Kuwait, Qatar, the United Arab Emirates, Oman, and Yemen. Parts of Jordan, Syria, and Iraq also lie within the desert. The northwestern Arabian Desert is also known as the Syrian Desert. For location, see **Desert** (map).

Most of the Arabian Desert consists of barren, stony highlands and plains, but sand in the form of dunes and thin sheets is common. An area in the southeast called Rub al Khali is the largest continuous area of desert sand on the earth. It covers about 250,000 square miles (647,500 square kilometers).

Average annual rainfall in most of the Arabian Desert is less than 4 inches (10 centimeters). Mountainous areas in the southwest get up to 20 inches (50 centimeters). Most of the desert is hot all year, but freezing temperatures occur in some areas in winter. Wayne Lambert

See also **Syrian Desert.**

Arabian Nights, a collection of about 200 stories, is probably the most famous piece of Arabic literature in the West. It includes the adventures of such well-known characters as Aladdin, Ali Baba, and Sinbad.

The *Arabian Nights,* also called *The Thousand and One Nights,* begins with the story of King Shahriyar, whose wife has been unfaithful. He orders her killed and vows to marry a new maiden each night and have her beheaded the next morning. One of the king's officials has a beautiful and talented daughter, Scheherazade, who insists on being the ruler's bride. She asks her sister to come to the bedchamber on the wedding night and request permission for Scheherazade to tell one last story. The king agrees, and she tells a tale so entertaining that he allows her to live another day to finish it. One story leads to another, and Scheherazade tells tales for 1,001 nights. By then, the king has fallen in love with her.

The stories of the *Arabian Nights* are folk tales from Arabia, Egypt, India, Persia, and other countries. The work in its present form was written in Arabic about 1500. In the early 1700's, Jean Antoine Galland translated the *Arabian Nights* into French. John Payne and Sir Richard Francis Burton wrote English translations of the collection in the 1880's. Dick Davis

See also **Burton, Sir Richard Francis; Genie.**

Arabian Peninsula, in southwestern Asia, is a vast land that is largely desert. Saudi Arabia occupies most of the peninsula. The other countries on the peninsula are Yemen, Oman, United Arab Emirates, Qatar, and Kuwait. Bahrain, an island country, lies just east of the peninsula. The Arabian Peninsula has an area of about 1,160,000 square miles (3,004,000 square kilometers). Most of it is dry wasteland. Rain seldom falls in some parts, and temperatures in the interior may rise to 130 °F (54 °C). But in parts of Saudi Arabia, Yemen, Oman, and the United Arab Emirates, rainfall and irrigation support farming. The peninsula is an area of great economic importance because it has large deposits of petroleum.

For detailed information on the Arabian Peninsula, see Saudi Arabia and the articles on the region's other countries. See also Arabs. Malcolm C. Peck

Arabian Sea, part of the Indian Ocean, lies between the Arabian Peninsula and India. Iran and Pakistan border it on the north. For location, see Asia (map). The Red Sea, Gulf of Aden, Persian Gulf, and Gulf of Oman are arms of the Arabian Sea. Along the Indian coast are the gulfs of Kutch and Khambhat. The Indus, Narmada, and Tapti rivers empty into the Arabian Sea. The chief islands in the sea are the Laccadive Islands, off the west coast of India; Socotra, northeast of Somalia; and Masira and the Kuria Muria Islands, off Oman's coast. In ancient times, the Arabian Sea was an important shipping route. Goods from the Far East were brought by ship to its western shores and carried inland by camel caravans. Today, tankers pass through the sea to and from the Persian Gulf, where they take on cargoes of crude oil and petroleum products. Malcolm C. Peck

Arabic language is one of the world's most widely used languages. It is the official language of many Arab nations in the Middle East and northern Africa, including Egypt, Iraq, Jordan, Lebanon, Saudi Arabia, and Syria. For the general distribution of Arabic, see Language (map).

There are two types of Arabic, *spoken* and *written.* Spoken Arabic consists of dialects in different areas of the Arabic-speaking world. These dialects can be roughly divided into Gulf, Iraqi, Levantine, Maghrebi, North Egyptian, Saudi, South Egyptian and Sudanese, and Tunisian. These dialect areas can be subdivided further. Written Arabic serves as the standard written language of all Arab nations. It is the descendant of the language of the Quran, the sacred book of the Islamic religion. Arabs use a spoken form of written Arabic for radio and TV news broadcasts, and in plays and motion pictures. This form also serves as a common spoken language for Arabs who speak different dialects.

Arabic belongs to the Semitic language groups, and is thus related to Hebrew and Ethiopic. The Arabic alphabet has 28 symbols. The alphabet is written from right to left or from the top of the page to the bottom. The alphabet appears in the Alphabet article. Many English words come from Arabic. They include *alcohol, algebra, check, checkmate, lute, magazine,* and *tariff.*

No one knows when Arabic originally developed, but people of the Arabian Peninsula were the first to use it. During the A.D. 600's, Islam spread throughout southwestern Asia and northern Africa, and the Arabic language was introduced in these areas.

Since the mid-1900's, many Arab countries have played an increasingly important role in world affairs. As a result, Arabic has become a major language in international business and politics. Roger Allen

See also Arabic literature; Arabs (Language); Quran; Semitic languages.

Arabic literature is the literature of people who speak the Arabic language, the official language of 19 Arab nations. Because it is also the language of the Quran, the holy book of Islam, Arabic is read and chanted by millions of Muslims throughout the world.

The earliest examples of Arabic literature date from the A.D. 500's, though they were not written down until up to 200 years later. Likewise, the Quran originally had no written form. When the Muslim community in the mid-600's felt the need for a recorded version of the sacred text, the Quran and other memorized texts from the earlier period were written down.

From its origin in the Arabian Peninsula, Islam spread to the west and east from the 600's to the 900's. With the spread of Islam, Arabic literature became known over a vast area, which, at its height, stretched from Spain across North Africa, through the Middle East, and to India. Today, the Arabic-speaking area still extends across North Africa and the Middle East.

From the earliest beginnings in the 500's to the present day, poetry has been the most important form of literary expression. During the 1800's, increased contacts with the Western world introduced Arab authors to new ideas and forms. They included the novel, short story, and theater. Poetry today retains its status as the most prestigious form of literature, but fiction has become very popular.

Poetry is described as the "register of the Arabs" in their literary tradition. Poetry is a powerful source of identity within Arab culture. From the beginning, it has been a public form, to be recited and sung. Tribal poets celebrated the qualities of their tribe: courage, loyalty, the beauty of their women, the speed of their horses, and the hardiness of their camels.

With the spread of Islam, poetry moved from the tribe in the desert to the court of the ruler in various Islamic cities, such as Baghdad, Iraq; Damascus and Aleppo, Syria; Cairo, Egypt; Fez, Morocco; and Córdoba, Spain. New themes were added, including wine, hunting, philosophical reflections on the individual's role in life, and the glory of the ruler. These themes were mostly expressed in the ancient poetic forms. However, new poetic structures emerged, particularly in Spain starting in the 900's, which combined aspects of both Arabic and Spanish poetry. Among the most famous classical poets are Imru al-Qays, Abu Nuwas, Abu Tammam, al-Mutanabbi, and al-Ma'arri.

In the 1900's, Arab poets imported Western forms, such as free verse and the prose poem. Perhaps most significantly, Arab poets felt free to break with tradition and compose their poems in a variety of forms and on a range of topics unavailable to their predecessors. Among the major poets of the 1900's were Kahlil Gibran, Khalil Hawi, and Adunis from Lebanon; Badr Shakir al-Sayyab from Iraq; and Salah 'Abd al-Sabur from Egypt.

Fiction. Several types of stories are found in early Arabic literature. For example, the *maqamah* usually contains short, witty narratives in which two characters visit cities through the Middle East. They observe the

way people behave and play tricks on them. From the 1300's, the famous collection of stories called *The Thousand and One Nights,* or *Arabian Nights,* was gathered. These tales were mostly performed in public by storytellers. Written versions were fairly rare until they were translated into Western languages.

In the 1900's, the novel and short story became popular in Arabian literature. The most famous modern fiction writer is Naguib Mahfouz, an Egyptian who in 1988 became the first Arab author to win the Nobel Prize for literature. Other important modern fiction writers include Yusuf Idris and Gamal al-Ghitani from Egypt, al-Tayyib Salih from the Sudan, Emile Habibi from Palestine, Hanan al-Shaykh from Lebanon, and Zakariyya Tamir from Syria.

Drama. Before the 1800's, there were several types of dramatic performances in the Arab world, though few of them were written down. In the 1800's, Arab writers visited Europe, where they saw plays performed. They began the process of transferring the form to the Arab world. One of the first major dramatists was Tawfiq al-Hakim of Egypt. He published many plays, ranging from one-act comedies of manners to long tragedies.

Since the 1950's, drama has flourished in many Arab countries. The most famous playwrights include Alfred Farag and Yusuf Idris of Egypt, Sa'dallah Wannus of Syria, Al-Tayyib al-Siddiqi of Morocco, and Yusuf al-'Ani of Iraq. Roger Allen

Arabic numerals, *AR uh bihk,* also called *Hindu-Arabic numerals,* are the most common symbols used to represent numbers. Every number can be expressed in Arabic numerals by using 10 basic symbols, alone or in combination. The basic symbols, called *digits,* are 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9. The position of a digit in an Arabic numeral determines its value. For example, the Arabic numeral for the number two hundred thirty-seven is the sequence of digits 237. In this numeral, the digit 2 has a value of two hundred, the digit 3 has a value of thirty, and the digit 7 has a value of seven. The Arabic numeral for the number seven thousand three is 7,003. In this case, the digit 7 has a value of seven thousand, and the digit 3 has a value of three. The digit 0 (zero) fills empty positions so that the other digits have their proper values. See Decimal system.

Scholars do not know how Arabic numerals originated. But the symbols for all the digits except zero probably originated with the Hindus in India, possibly as early as the 200's B.C. The Hindus developed the zero sometime after A.D. 600. The word *zero* probably comes from the Arabic form of the Hindu word *sunya,* which means *empty* (see Zero). Traders and merchants helped spread the Arabic numeral system across the Mediterranean region, especially into Spain. Beginning in the 800's, merchants and scholars introduced it throughout the rest of Europe. The system came into general use in Europe when the digit symbols were standardized. This was brought about by the invention of the printing press in the mid-1400's. Nadine L. Verderber

Andy Hernandez, Sipa Press

Arabs follow many ways of life. But they are united mainly by their history and their culture. Most Arabs are Muslims, like these men praying on a street in Amman, Jordan. Islam requires its followers to pray five times a day.

Arabs

Arabs are a large group of people whose native language is Arabic and who share a common history and culture. Most Arabs live in the Middle East, which spreads across southwestern Asia and northern Africa. Arabs also have migrated to such countries as Brazil, Britain, Canada, France, and the United States.

This article discusses the approximately 200 million Arabs who live in the *Arab world.* There are two chief definitions of the Arab world, a political definition and a *linguistic* (language-related) one. Politically, the Arab world is usually said to include 18 countries—Algeria, Bahrain, Egypt, Iraq, Jordan, Kuwait, Lebanon, Libya, Mauritania, Morocco, Oman, Qatar, Saudi Arabia, Sudan, Syria, Tunisia, the United Arab Emirates, and Yemen. These are called Arab countries because a majority of their people are Arabs and their governments regard themselves as Arab. Two other countries—Djibouti and Somalia—have only small Arab populations, but they are sometimes included in this political definition because they belong to an organization of Arab states called the Arab League.

In a linguistic sense, the term *Arab world* refers to those areas where most people speak Arabic as their native language. This linguistic definition differs from the political one because some Arab countries include large areas populated by non-Arabs, and some non-Arab countries have significant Arab minorities. For example, the Kurds of Iraq and the Berbers of northern Africa are non-Arabs inhabiting Arab countries. At the same time, many Arabs live within the borders of such

Fred M. Donner, the contributor of this article, is Associate Professor of Islamic History at the University of Chicago.

non-Arab nations as Iran and Israel. In this article, the term *Arab world* chiefly refers to the 18 countries usually considered Arab in a political sense.

Originally, the word *Arab* was probably associated with the camel-herding nomadic tribes of the Arabian Peninsula and nearby parts of the Middle East. Later, it was applied to settled people who spoke the Arabic language. The number of Arabs who follow a nomadic way of life has gradually shrunk over the years. Today, almost all Arabs live in cities, towns, or villages.

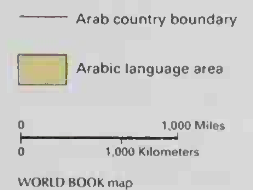
Arabs today are united mainly by aspects of their culture—above all, by the Arabic language and Arabic literature and music. Religious and historical factors also bind the Arabs together. Most Arabs are Muslims, followers of a religion called Islam. The Arabs' rise to political and cultural importance during the Middle Ages was closely associated with the rise of Islam. For this reason, even non-Muslim Arabs hold Islam in special regard. The modern Arab identity emerged during the 1800's and 1900's, when most Arab lands were colonies of European powers. Thus, Arabs also share a sense of themselves as former subjects of European rule.

Despite this common heritage, deep differences exist among the Arab countries. For example, many Arab countries possess valuable petroleum deposits. The export of oil has made some of these countries, such as Kuwait and Qatar, extremely rich. But such countries as Sudan and Yemen remain poor. Some countries, including Jordan and Lebanon, have highly urban societies, where many people work in industry or commerce. Others, such as Mauritania and Yemen, have rural societies and rely on farming or herding. Some nations, such as Lebanon and Tunisia, have been heavily influenced by Western culture. Others, including Oman and Saudi Arabia, remain strongly traditional. These and other differences have caused conflicts, and even wars, within the Arab world.

Land of the Arabs

The Arab world extends over about 5 million square miles (13 million square kilometers). It covers roughly three main regions: the Arabian Peninsula (sometimes called Arabia); northern Africa; and part of an area called the Fertile Crescent, which includes Iraq, Jordan,

Eddie Adams, Contact



The Egyptian potato farmers shown here live in one of the few fertile regions of the Arab world. Despite its vast area, only a small percentage of Arab land is suitable for human settlement.

Lebanon, Syria, and the historical land of Palestine. Palestine today consists of the West Bank, the Gaza Strip, and the non-Arab state of Israel.

Despite the vast area of the Arab world, only a small percentage of it is suitable for human settlement. Much of the region is hot and dry, and it has large desert areas. These include the Sahara in northern Africa, the deserts of the Arabian Peninsula, and the Syrian Desert. At the other extreme are snow-capped mountains, such as those of the Grand Atlas range in Morocco and parts of the Lebanon Mountains. The vast majority of Arabs live in well-watered hilly regions, fertile river valleys, and humid coastal areas. The most densely settled area is the Nile Valley and Nile River Delta of Egypt. Virtually all the people of Egypt—about a fourth of all Arabs—live in this area. A large number of Iraq's people live in the fertile delta between the Tigris and Euphrates rivers. Other population centers include the coastal and hill

The Arab world has both a political and a *linguistic* (language-related) definition. Politically, it includes 18 countries in the Middle East and across northern Africa. Western Sahara, also shown, is claimed by Morocco. In a linguistic sense, *Arab world* refers to those areas where most people speak Arabic as their native language.

WORLD BOOK map

Mark Edwards, Sygma

Harsh, sparsely populated deserts cover much of the Arab world. Nomads once roamed these deserts with their herds, but today nearly all livestock herders live in towns or villages. The Sudanese goatherds in this photograph are drawing water from a well.

zones of northwestern Africa and of Lebanon, Syria, and parts of Palestine.

Historically, the scarcity of water and the resulting limited farming capacity have hampered population growth and economic development in Arab lands. However, they may have encouraged the development of trade, especially before the 1800's.

Life in the Arab world

When people think of Arabs, they often picture nomadic herders, or Bedouins, living in tents and crossing the desert with their camels, sheep, goats, or cattle in search of water and grazing land. Today, less than 1 percent of Arabs are nomads. Livestock herding now resembles ranching rather than nomadic life, and animals—even camels—are usually transported by truck.

About half of all Arabs live in cities and large towns. Many of these people work in factories or in such fields as business, government, and health care. Most other Arabs live in villages or small towns and work as farmers or in local trades. In many Arab countries, the creation of modern road networks has enabled industries to spread to rural areas, and some villagers have jobs in nearby factories.

Language. Virtually all people who consider themselves Arabs speak Arabic as their native language. But the forms of spoken Arabic vary considerably from one region to another. Arabs who speak different dialects can communicate through a common form of Arabic, usually called Modern Standard Arabic (MSA)—*fusha* in Arabic. MSA is a simplified version of the Arabic of the Quran, the sacred book of Islam. MSA serves as the chief form of written Arabic in all Arab lands. It is also the language used in most schools and in radio and TV news broadcasts throughout the Arab world.

Many other languages are used in various parts of the Arab world. For example, French is widely spoken in the former French colonies of Algeria, Morocco, and Tunisia, where the French language struck deep roots in cultural and political life.

Religion. About 90 percent of Arabs are Muslims. Most belong to the Sunni branch of Islam. However, significant Shiite Muslim communities exist in Iraq, the eastern Arabian Peninsula, and Lebanon. Some Shiites live in most other Arab countries. Small numbers of Arabs belong to other Muslim groups.

Druses, who follow a religion related to Islam, live mainly in Lebanon, Syria, and the historical region of Palestine. Most non-Muslim Arabs are Christians. The Copts of Egypt belong to one of the oldest Christian sects. Other Christian Arabs belong to various Eastern Orthodox, Roman Catholic, or Protestant churches. They live mainly in Iraq, Jordan, Lebanon, Syria, and Palestine. Small communities of Jews live in some Arab countries.

Family life. Arabs strongly value family ties and hospitality. Traditionally, Arabs have placed great importance on belonging to family or kinship groups, including the *extended family, clan,* and *tribe.* An extended family includes members of two or more generations, many of them sharing one home. A clan consists of several related families. A tribe might include hundreds of families. In the past, most social and even many business activities took place within these groups. Often, parents sought marriage partners for their children within the clan or tribe. The kinship system also stressed hospitality as a source of honor. A host who richly entertained a guest raised the standing of the entire tribe.

Today, some kinship ties have loosened, especially in the cities. The impact of Western values and the need for some people to move far from home to earn a living have tended to weaken family relationships. But for many Arabs, the family continues to be the main source of social and economic support. Many rural Arabs still live in extended families, and even most city dwellers live near relatives. Many Arab children are raised by grandparents, aunts, uncles, and other relatives in addition to their parents. It is still common for parents to arrange their children's marriages.

Traditionally, women formed the focus of family life. They supervised the raising of children, the preparation of meals, and the organizing of family celebrations. In some countries, economic pressures and educational opportunities have led a growing number of women to work outside the home.

Education. Until the 1900's, religious authorities operated most schools in the Arab world. Today, all Arab

nations also have free, nonreligious primary and secondary schools. In most Arab countries, about 90 percent of all children receive at least an elementary education. Some Arabs consider education less important for girls than for boys. But all Arab nations provide public schooling at all levels for both sexes.

Some Arab institutions of higher education have existed for centuries. For example, al-Azhar University in Cairo, Egypt, was founded about 970. Today, there are approximately 85 universities in the Arab world.

Literature and the arts. Arabic literature began about 1,500 years ago. The first major Arabic work was the Quran, the holy book of Islam, which dates to the 600's. The Quran is still regarded as the greatest masterpiece of Arabic literary style. See Quran.

Classical Arabic literature extends from the time of the Quran to about the mid-1800's and includes a rich tradition in both poetry and prose. Prose literature covers a wide range of forms and styles, from the popular tales of the *Arabian Nights* to such scholarly works as the *Muqaddima* of Ibn Khaldun, a historian of the 1300's. The *Muqaddima* examines the rise and fall of civilizations. A highly developed poetic tradition flourished beginning in the 700's. Arabic poets produced verses of great lyric beauty as well as poetic works expressing deep philosophical or religious thought.

Today, poetry remains especially beloved by Arabs. Nearly all Arabs delight in reciting and listening to verses, and many compose their own poetry. Stories, novels, and plays are also published in great numbers.

Arabs took part in the flowering of art and architecture throughout the Muslim world from the mid-700's to about 1700 (see **Islamic art**). Such traditional crafts as glass blowing, metalworking, and pottery making still flourish today. Since 1900, painting and sculpture have become popular in many Arab lands.

Traditional Arab music, with its strong rhythmic patterns, is closely linked with the poetic tradition. Today, many musicians experiment with new styles, mixing aspects of Arab and non-Arab music or combining styles from different parts of the Arab world.

Richard Steedman, The Stock Market

Traditional Arab architecture places great importance on privacy. Many houses are constructed around a central courtyard, like the homes in this neighborhood in Damascus, Syria.

Food and drink. Beans, chickpeas, lentils, and rice are basic foods in most Arab lands. They may be made into stews, or cooked with water, oil, vegetables, and seasonings to form various pastes. People eat the pastes by scooping up mouthfuls with thin Arab bread, called *pita* in the West. In northern Africa, *couscous* (steamed cracked wheat) replaces rice as a basic food to some extent. Arabs also enjoy meat, fish, and a wide variety of salads and cooked vegetables. Sesame seed paste or oil adds a special flavor to many dishes. Some form of yogurt often accompanies meals.

Fresh and dried fruits are the main desserts. But sweet pastries such as *baklava,* which is made with honey and chopped nuts, are served on special occasions. Coffee and tea are the most popular beverages.

Clothing. Because of the hot climate of most Arab lands, both men and women have traditionally worn loose-fitting garments that cover most of the body and head, shielding them from the sun. For women, such garments usually consist of a floor-length dress and a headscarf or hood. In areas where Islam is strong, women may wear a veil in public. Many women wear Western-style dresses or slacks. But they rarely wear short or sleeveless dresses or let their hair hang free.

Traditional men's clothing might consist of a full-length robe, or a cloak over some combination of shirt, vest, skirt, and *loincloth* (a cloth wrapped around the hips and between the thighs). Some farmers wear baggy trousers. Many men also wear a turban, skullcap, or *kaffiyeh*—a loose, folded headscarf, often held in place by a decorative cord called an *agal,* also spelled *iqal.* Today, many men wear Western-style clothing, especially in the cities. Some men combine elements of Western and traditional dress. For example, they may wear a Western-style sports jacket over a robe.

Shelter. Most rural Arabs live in one- or two-story houses of brick, mud-brick, or stone. Mud-brick architecture, in particular, takes a wide variety of forms, from simple rectangular structures to the beehive-shaped houses of northern Syria (see **Syria** [picture]). Mud-brick is cheap and easy to use, and it provides excellent insulation against heat and cold. However, concrete and cinder blocks are increasingly replacing mud-brick as building materials.

Western-style apartment buildings are common in large cities. But traditional Arab architecture can also be found in urban areas. The distinctive many-storied mud-brick or stone buildings of Yemen and southern Saudi Arabia rank among the world's first "skyscrapers" (see Yemen [picture]). Privacy is an important factor in much Arab architecture, both urban and rural. Many homes or buildings open onto a private or semiprivate central courtyard, while blank walls face the street.

Economy. For centuries, the Arab world was a crossroads of international commerce. Arab and other merchants carried such goods as spices, textiles, and glass between Asia, Africa, and Europe. Beginning in the 1700's, the expansion of European commerce and industry led to economic decline in the Arab world. Then, during the 1900's, petroleum became one of the world's most important economic resources. Together, the Arab lands hold about three-fifths of the world's reserves of

Robert Harding Picture Library

Petroleum, the Arab world's most important resource, has brought great wealth to some Arab countries. Arab lands hold about three-fifths of the world's oil reserves.

oil. Petroleum has brought enormous prosperity to many Arab governments, permitting rapid improvement in education, health care, transportation, and other services. But some Arab countries still face great poverty.

The countries most dependent on petroleum include Iraq, Kuwait, Libya, Oman, Qatar, Saudi Arabia, and the United Arab Emirates. But nearly all Arab states rely heavily on the export of petroleum, other raw materials, and agricultural products. Manufacturing is developing slowly in the Arab world. Only Jordan, Lebanon, Morocco, Tunisia, and, to a lesser extent, Egypt receive a significant amount of income from manufacturing.

A scarcity of fresh water limits agricultural development in most areas. Agriculture can be extended only through large-scale irrigation projects, which are expensive and unreliable. In addition, in many countries, a small number of wealthy landowners once controlled most of the farmland, which was worked by poverty-stricken peasants. Since the mid-1900's, Arab governments have put more land in the hands of the farmworkers. But most of them remain poor.

History

The Arabs before Islam. The word *Arab* first appears in documents about 850 B.C. The documents—written by the Assyrians, a people of what is now Iraq—suggest that the early Arabs were nomadic camel herders centered in what are now Jordan and Israel. The Arabs then spread north and east through present-day Syria and Iraq, and south into the Arabian Peninsula.

About the 400's B.C., Arab families or tribes began to establish small states, often at centers for the overland caravan trade. Two important states were centered at Petra and Palmyra. Petra, in what is now Jordan, was the capital of Arabs known as Nabateans. It was conquered by the Romans in A.D. 106 but continued to flourish until the early A.D. 200's. Palmyra, in the Syrian Desert, fell under Roman domination by about A.D. 160. It reached its height in the mid-200's.

The rise and spread of Islam. Muslims believe that God revealed the teachings of Islam to the prophet Muhammad. Muhammad was born about A.D. 570 and grew up in Mecca, a town in western Arabia. He began to preach about 610. Muhammad founded the first community of Muslims in Medina, then called Yathrib, north of Mecca. This community rapidly grew into a state that controlled much of the peninsula.

After Muhammad's death in 632, leaders called *caliphs* headed the Islamic state. Armies under the caliphs soon seized the rest of Arabia and an area stretching from Egypt to Iran. The result was a vast new empire dominated by Arabian Muslims, with Islam as the official religion of the empire and Arabic as the official language.

For several hundred years, the political life of the empire was dominated by three families from Muhammad's tribe of Quraysh: the Umayyads, the Abbasids, and the Alids. The Umayyads ruled from 661 to 750. They extended the empire as far west as Spain and as far east as India. In 750, the Umayyads were overthrown by the Abbasids, though they retained control of Spain. After about 850, the Abbasids increasingly lost control of distant parts of the empire, which became independent under local Islamic *dynasties* (ruling families). The Alids, the main rivals of the Umayyads and Abbasids, made many unsuccessful attempts to overthrow them. The Alids finally established the Fatimid dynasty in northern Africa in 909. It ruled until 1171.

A sense of Arab identity seems to have emerged in connection with the spread of Islam. This sense of "Arabness" resulted partly from use of the Arabic language and partly from pride in the Islamic empire. It also stemmed from identification with the rich literary culture that developed under the Umayyads and Abbasids. For more information on the history of this period, see Muslims (The Muslim Empire).

From the 1000's to the 1500's, parts of the eastern Arab lands were conquered by several waves of non-Arab invaders. Chief among these were the Seljuk Turks and the Mongols, who executed the last Abbasid caliph in 1258. Northern Africa remained in the hands of local groups, mainly Arabs and Berbers.

Ottoman and European rule. By the mid-1500's, nearly all the Arab lands had come under the control of the Ottoman Empire, centered in what is now Turkey. The Arab lands were an important part of the empire. Many high Ottoman officials were of Arab origin, and the Arabs regarded themselves as Ottomans and Muslims, not as Arabs.

Beginning in the mid-1700's, the rapid economic and military development of much of Europe gave European states an advantage over the Ottomans. In their efforts to modernize their economies, the Ottomans often developed large debts to European financiers. The financiers then sometimes persuaded their governments to seize economic or political control of Ottoman possessions to ensure repayment of the debts. In other cases, European nations simply invaded Ottoman territories. France began occupation of Algeria in 1830, and it controlled Tunisia and Morocco by the early 1900's. Beginning in the late 1800's, Britain took over Egypt and Sudan, and it controlled many coastal areas of Arabia. Italy gained control of Libya in 1912.

Arab nationalism arose against the background of both European colonial rule and increasing nationalist feeling among the Ottoman Empire's Turkish majority. It was part of a nationalist idea that spread through much of the world during the 1800's and 1900's. This idea stated that humanity was divided into distinct nations or peoples. The members of each nation shared a common history and language, and each nation had a historic claim to a particular national homeland.

Significant Arab nationalist movements did not develop until the early 1900's. These movements then took two forms. In some cases, nationalist feeling arose around particular areas. In others, it centered on the Arabic language as a source of unity. This form of nationalism later grew into the movement for Arab political unification called *Pan-Arabism.*

After the Ottoman Empire entered World War I on the side of Germany in 1914, the United Kingdom helped stir up an Arab nationalist revolt against the Ottomans. The United Kingdom promised the leaders of the revolt that it would recognize an independent Arab government in former Ottoman territories after the war. But the United Kingdom also made a secret agreement with France to divide these territories into British and French spheres of influence after the war. When World War I ended in 1918, the League of Nations—a forerunner of the United Nations—divided the Arab lands still held by the Ottomans between the United Kingdom and France. In turn, the United Kingdom and France were expected to supervise these lands—known as *mandated territories*—and help them attain self-government. The United Kingdom received mandates over Iraq and over Palestine, which then included present-day Jordan and Israel. France received what are now Syria and Lebanon.

Struggles for independence. By the early 1920's, the main centers of population in the Arab world had been split into more than 15 European colonies and *protectorates* (territories under partial control). These colonies had become divided politically, economically, and, increasingly, culturally. Because of these divisions, the goal of Pan-Arab unification became less important than that of independence within each colony.

© Bill Lyons

Arab nations are working to develop a wider variety of economic activities. These computer operators, members of a growing middle class, work for a Jordanian papermaking firm.

Beginning in the 1920's, the Arab countries gradually gained independence. Some, such as Bahrain and Kuwait, made the change peacefully. In others, notably Algeria, violent struggles took place. The last colonies to become independent—British-ruled Bahrain, Qatar, and the states that now make up the United Arab Emirates—did so in 1971.

Since independence. Traditionally, political life in most Arab lands had been dominated either by a small number of wealthy individuals or by the army. The European powers took limited steps toward developing institutions of democratic government in their Arab colonies. But they kept such institutions from becoming strong enough to threaten colonial rule. They also failed to create economic or educational systems that would stimulate the growth of a middle class. As a result, the independent Arab states have continued to be ruled by traditional wealthy families or by the army.

The independent Arab nations have struggled with other issues as well. These include (1) the search for unity and (2) the Arab-Israeli conflict.

The search for unity. Several times, two or three Arab nations have attempted to unite into a single state. For example, Syria and Egypt joined to form the United Arab Republic in 1958. The union ended when Syria withdrew in 1961. Such efforts have stemmed partly from a belief in Pan-Arabism. But in many cases, they also represented attempts by a weak government to maintain its rule by uniting with a stronger neighbor.

In 1945, seven countries founded the Arab League. Today, 21 countries and the Palestine Liberation Organization (PLO) belong to the league. The organization works to promote closer political, economic, and social relations among its members.

Pan-Arab unity remains an ideal for some Arabs. But the different economic needs and political goals of the Arab states have at times made them bitter rivals. The wealth of some Arab countries from petroleum exports has contributed greatly to tension. Petroleum-poor states resent the wealth of their richer neighbors and seek to share in the oil income. Disagreements have also occurred among petroleum exporters over pricing and production policies. Such disagreements helped set off the invasion of Kuwait by Iraq in 1990, which severely divided the Arab states. Several Arab countries, most notably Saudi Arabia and Egypt, took part in the Persian Gulf War in 1991 helping expel Iraqi forces from Kuwait.

The Arab-Israeli conflict can best be understood as a struggle between two nationalist movements, both of which claim Palestine as their national homeland. The conflict dates to the early 1900's, after significant numbers of European Jewish immigrants began to enter Palestine. In 1917, the United Kingdom declared its support for the creation of a Jewish homeland in Palestine. But the United Kingdom had also promised support for an independent Arab state in former Ottoman Arab provinces, including Palestine. Tension between the Arabs and the Jewish settlers grew, accompanied increasingly by violence on both sides.

In 1947, the United Nations adopted a plan dividing Palestine into an Arab state and a Jewish one. The Arabs rejected this plan, and in 1948 several Arab nations invaded the newly formed state of Israel. During the war

that followed, hundreds of thousands of Palestinian Arab refugees fled to neighboring Arab countries.

The war ended in 1949, but no peace treaty was signed. Since then, the Arab-Israeli conflict has been of major importance in the Arab world. Thousands of people died in wars fought in 1956, 1967, and 1973, and in an Israeli invasion of Lebanon in 1982. Thousands more have died in Palestinian guerrilla attacks and in two *intifadas* (uprisings) by Palestinians. The first intifada began in 1987 and lasted into the early 1990's. The second intifada began in 2000.

Egypt and Israel signed a peace treaty in 1979. In 1994, Jordan and Israel signed a declaration that formally ended the state of war between the two countries. But Israel has not made final peace agreements with Syria or with the Palestine Liberation Organization (PLO). The PLO is a group approved by Arab countries to represent the Palestinians. In 1993, Israel and the PLO agreed to a plan for Palestinian self-government in the Gaza Strip and the West Bank. Israel occupied those Arab lands in 1967. During the 1990's, Israel withdrew from most of the Gaza Strip and parts of the West Bank. But in 2000, peace talks between the two sides failed to resolve several remaining disagreements. Later that year, Palestinians began a violent intifada, and Israel responded with police crackdowns and military attacks.

The Arabs today continue to face major challenges. The problems of poverty, overpopulation, poor health care, and inadequate educational facilities are severe in some Arab states. In other countries—especially thinly populated ones—enormous oil wealth has provided high-quality medical care and education. But an effective way of bringing those benefits to poorer, more populated countries has yet to be found. In addition, the oil-rich states must plan carefully for the day when oil reserves run dry. Many of these countries are working to develop other economic activities that can help maintain their growth in the post-petroleum age.

Most Arab countries also must work to create strong institutions of multiparty, civilian government. Another challenge is to find ways to solve religious or ethnic conflicts, such as that between Arabs and Kurds in Iraq or among Sunni Muslims, Shiite Muslims, Christians, and Druses in Lebanon, as well as the Arab-Israeli dispute. Arabs also must deal with powerful conflicts between Islamic tradition and the influence of the West.

Field, Michael. *Inside the Arab World.* Harvard Univ. Pr., 1995.

Arachne, *uh RAK nee,* was a skilled weaver in Greek mythology. She boasted that she could weave fabrics more beautiful than those woven by Athena, the goddess of arts and crafts. Athena, disguised as an old woman, warned Arachne not to be so boastful. When Arachne scorned her advice, Athena revealed herself as a goddess and accepted Arachne's challenge to a weaving contest.

Athena wove a tapestry that pictured mortals being punished by the gods for their pride. Arachne's work showed the shocking misbehavior of gods and goddesses. When Athena saw that Arachne's work was as beautiful as her own, the goddess angrily ripped the fabric. As Arachne attempted to hang herself in terror, Athena took pity on her and transformed her into a spider. Arachne's skill survived in the spinning of webs by spiders. Nancy Felson

Arachnid, *uh RAK nihd,* is the name of any member of a class of small, insectlike, land animals. The best-known arachnids are spiders, ticks, mites, scorpions, and daddy longlegs, or harvestmen. Arachnids, unlike insects, have no wings. Their bodies are divided into two main parts, the abdomen and the *cephalothorax,* which consists of the head and the thorax joined together. Insects, however, have three main body parts: the head, the thorax, and the abdomen. Arachnids have four pairs of legs but have no *antennae* (feelers). Insects have antennae, but only three pairs of legs.

Arachnids have from one to six pairs of simple eyes. Some species are eyeless. Unlike insects, arachnids have no *compound eyes* (eyes that are made up of many smaller eyes crowded together). Some arachnids breathe like insects by means of air tubes. Others have breathing organs somewhat like lungs, called *book lungs.* These are small sacs within the abdomen, connected with the outer air by small openings. Within each sac are many layers of tissue resembling the leaves of a book. The air enters the sac through the small openings and furnishes oxygen to the blood flowing through the leaves. Most spiders have air tubes and book lungs.

Some arachnids are harmful to people. Certain of them can inflict poisonous bites or stings. Others suck the blood of human beings and animals, and may carry serious diseases. Many arachnids are helpful to people because they eat harmful insects. James E. Carico

Scientific classification. Arachnids make up the class Arachnida in the phylum Arthropoda.

Arafat, *AHR uh FAT,* **Yasir** (1929-), has been chairman of the Palestine Liberation Organization (PLO) since 1969 and president of the Palestinian Authority since 1996. The PLO is an alliance of Palestinian Arab groups that work to establish an Arab state in what was once Palestine. The area that made up Palestine now consists mainly of Israel, the Gaza Strip, and the West Bank. The Palestinian Authority was created in 1994 to govern Palestinian-controlled parts of the West Bank and Gaza Strip.

Arafat was born in 1929, probably on August 24. He claims he was born in Jerusalem, in what was then the British mandate of Palestine, but many sources say he was born in Cairo, Egypt. His full name is Mohammed Abdel-Raouf Arafat al-Qudwa al-Husseini. He acquired the nickname Yasir, which means *easygoing,* as a teenager. He earned a degree in civil engineering at Cairo University. In the 1950's, he helped organize Arab guerrilla groups, including *Al Fatah,* now part of the PLO. Beginning in the 1960's, he helped plan many Al Fatah raids against Israel. Israel then attacked PLO bases. Arafat addressed the United Nations (UN) General Assembly in 1974, and the UN then recognized the PLO as the representative of Palestinian Arabs.

©Barthelemy, Sipa Press
Yasir Arafat

In 1983, fighting broke out between PLO supporters of Arafat and those who opposed him. The rebels forced Arafat and his supporters to leave their bases in northern Lebanon. But Arafat remained as PLO chairman.

The PLO did not recognize Israel's right to exist. But in 1988, Arafat persuaded the PLO to accept Israel's right to exist alongside a Palestinian state in the Gaza Strip and West Bank. Israel had occupied them after the 1967 Arab-Israeli war. The PLO declared the existence of the state and elected Arafat its president. But Israel continued to occupy and, in effect, govern the areas.

In 1993, the PLO—under Arafat's leadership—and Israel gave recognition to each other. In 1993 and 1995, they signed agreements that led to the withdrawal of Israeli troops from the Gaza Strip and most West Bank towns by early 1996. As the Israelis withdrew, the Palestinian Authority took control of these areas. In 1994, Arafat and the Israeli leaders Yitzhak Rabin and Shimon Peres shared the Nobel Peace Prize for their peace efforts. In January 1996, Arafat was elected president of the Palestinian Authority. Michael C. Hudson

Aragon. See Castile and Aragon.

Aral Sea, *AR ul,* is a large saltwater lake in Kazakhstan and Uzbekistan (see Asia [physical map]). It is one of the world's largest inland bodies of water. Since the early 1960's, however, irrigation has caused the lake to shrink to about 40 percent of its former size. The lake now covers about 11,000 square miles (28,500 square kilometers). It contains many islands. Leslie Dienes

Aramaic language, *AR uh MAY ihk,* is a language of the Middle East. It belongs to the Semitic family of languages, along with Hebrew and Arabic. The earliest evidence of Aramaic dates from about 900 B.C. Jesus Christ and His disciples spoke Aramaic. Aramaic is still spoken by Assyrian Christians in isolated areas of Syria, Turkey, Iraq, and Iran. The long history of Aramaic and the wide extent of its use have resulted in many dialects.

The earliest samples of Aramaic writing date from about 900 B.C. Parts of the Biblical books of Ezra and Daniel and some of the ancient manuscripts known as the Dead Sea Scrolls were written in Aramaic. A number of major Jewish works of the period from A.D. 1 to 600 were composed in Aramaic. R. F. G. Sweet

See also Hebrew language; Semitic languages.

Aramid is a manufactured fiber that is chemically similar to nylon but is stronger by weight than steel. Like nylon fibers, aramids are made of chemical compounds called *amides.* The amides are linked to *aromatic rings* (rings of six carbon atoms) to form long, chainlike molecules called *polymers.* But unlike the amides in nylons, at least 85 percent of the amides in aramids are attached directly to two aromatic rings. This arrangement results in a stronger and more heat-resistant fiber than nylon.

Aramids are used in many products, including tires, parachutes, reinforced tape, and bulletproof vests. They are also used as a reinforcing material in boat hulls and the bodies of aircraft. Aramids are manufactured under the trade names Kevlar and Nomex. Richard V. Gregory

Arapaho Indians, *uh RAP uh hoh,* are a tribe who once hunted on the Great Plains of North America. They moved about frequently, living in tepees and following the buffalo herds, their major source of food. At first, the Arapaho fought to keep white settlers from taking their hunting lands. But the Arapaho Indians made peace in the 1860's and 1870's and moved to reservations.

The Arapaho religion involved belief in a powerful spirit world. The most important religious ceremony was the *sun dance* (see Sun dance). The men belonged to special clubs that performed sacred ceremonies and enforced tribal laws. A women's group that was called the Buffalo Society also carried out certain rituals.

Today, there are about 4,500 Arapaho. They have split into three groups: (1) the Southern Arapaho of Oklahoma; (2) the Northern Arapaho of Wyoming; and (3) the Gros Ventre (see Gros Ventre Indians). The Arapaho work in farming, ranching, and other occupations. The Northern Arapaho also receive income from oil and natural gas obtained from their land. Stanton K. Tefft

Ararat, *AR uh rat,* was the country where, according to the Bible, Noah's ark landed after the Deluge. The Biblical story is told in Genesis 6-8. Ararat was the area surrounding Lake Van in ancient Armenia, now part of Turkey. Many people believe that Noah's ark came to rest on Mount Massis, the tallest mountain in Ararat, known today as Mount Ararat. However, the Aramaic and Syriac translations of the story speak of the ark landing in the mountains of Kurdistan, southeast of Lake Van.

The land of Ararat is also mentioned in II Kings 19:37 and Isaiah 37:38. These passages tell that the sons of the Assyrian king Sennacherib fled to Ararat after they killed their father. Jacob Neusner

See also Armenia (map); Noah.

Araucanian Indians, *AR aw KAY nee un,* a large group in South America, are famous for their long and successful resistance to the Spaniards. A famous Spanish epic poem, *La Araucana,* written by Alonso de Ercilla y Zúñiga, describes these struggles. The Araucanians were formerly divided into many tribes. The Picunche, Mapuche, and Huilliche lived west of the Andes along the central coast of Chile; the Pehuenche inhabited the central Chilean highlands; and the Argentine Araucanians lived east of the Andes. Their way of life varied, but most were vegetarians. Piñons from the Chilean pines provided a staple food for some. Others farmed, growing maize, squash, beans, and potatoes. Those who lived along the coast depended heavily on fishing.

The Araucanians originally lived in coastal Chile. They took horses from the Spanish in the mid-1500's and began moving into Argentina. An Argentine army defeated them in 1879, and Chilean forces subdued other groups in 1883. Today, there are about 250,000 Araucanians. Most of them are farmers. Roberto DaMatta

Arawak Indians, *AH rah wahk,* were the first American Indians that Christopher Columbus met in the Americas in 1492. The Arawak lived in most of the islands of the West Indies. Arawak who lived in what are now eastern Cuba and the Caribbean islands of Hispaniola and Puerto Rico are also called Taino Indians. Other groups of Indians speaking Arawakan languages lived in the Amazon River Basin and other parts of South America.

Arawak villages were organized into chiefdoms, with up to 80 villages under the leadership of one *cacique* (pronounced *kuh SEEK),* or chief. The Arawak grew corn, yams, cotton, and *cassava,* a root crop. Their diet included fish, shellfish, and the meat of iguanas, sea turtles, and a rodent called the *hutia.*

Many Arawak died from diseases brought to the Americas by European explorers. Spanish colonists forced the Arawak to mine gold or perform other physical labor. This forced labor further reduced the Arawak population and destroyed their traditional way of life. By the mid-1500's, nearly all the Arawak Indians of the Caribbean had died. Samuel M. Wilson

Arbitration, *AHR buh TRAY shuhn,* is the judging of a dispute by one or more impartial persons whose decision will be final and binding. The judges are called *arbitrators* or members of an *arbitration board.* The arbitrators are chosen by the parties to the dispute, or by some neutral agency designated by them. The decision of the arbitrators is known as an *award.* Arbitration may be employed between individuals, groups, or nations.

Commercial arbitration is a process in which businesses submit their disputes to one or more arbitrators. It has been practiced in Europe for many years. In the United States, the American Arbitration Association maintains panels of arbitrators. The decisions of these panels have been enforced by the courts of many states.

Industrial, or labor, arbitration is the settlement of disputes between employers and labor. In *voluntary arbitration,* management and labor agree to submit the dispute to arbitration and to abide by the award. In *compulsory arbitration,* the government orders a dispute to be submitted to arbitration because the dispute affects the public interest. Compulsory arbitration is usually ordered only after voluntary methods have failed.

Most industrial disputes involve fixing wages, hours, and conditions of labor. Arbitration is sometimes a way of settling grievances and avoiding or ending costly strikes and lockouts.

In the United States, arbitration has been used most widely in disputes over existing contracts, especially in the railroad industry. In 1963, Congress prevented a national railroad strike over work rules by requiring compulsory arbitration. It was the first compulsory arbitration law ever passed in peacetime.

International arbitration is the settlement of disputes that arise between two or more nations. The dispute is submitted to judges chosen because of their knowledge of international affairs. These judges may be members of the Permanent Court of Arbitration or may be other individuals selected for the purpose. Their decisions are regarded as binding. Daniel Quinn Mills

Arbor Day is a day set apart for planting trees. It is observed especially by schoolchildren. Most states in the United States and most provinces of Canada celebrate Arbor Day. Arbor Day is celebrated as a legal holiday in some states and provinces. The Southern States and Hawaii celebrate it at various times from December to March. Most Northern States celebrate it in April or May. Many other countries also celebrate Arbor Day by planting trees, or they have other special days or weeks for tree planting.

Arbor Day began in Nebraska. Julius Sterling Morton, a newspaper publisher, realized that trees would enrich the soil and conserve moisture in it. Through his efforts, April 10, 1872, was set aside as Nebraska's first Arbor Day. After Morton died, the Nebraska Legislature changed the date of Arbor Day to his birthday, April 22, and made it a legal holiday. Jack Santino

See also Morton, Julius Sterling; Nebraska (Places to visit); Tree (Planting and caring for trees).

Arboretum, *AHR buh REE tuhm,* is an outdoor laboratory where trees, shrubs, and other woody plants are grown under natural conditions. The plants are often arranged and labeled according to the family and the relationship to other plants of the same species. Most arboretums are open to the public and have helped create widespread appreciation of this kind of landscaped botanical garden. They have also increased the scientific methods of growing hardier and more beautiful plants. Most arboretums also conduct experiments in raising new and rare plants. Richard C. Schlesinger

Arbutus, *ahr BYOO tuhs,* is the name given to a number of evergreen plants of the heath family. Most of them are shrubs or trees. In eastern and central Canada and the United States, the best-known is the *trailing arbutus,* a creeping plant with fragrant white or pink flowers. In New England, it is called *mayflower.* The Pilgrims are said to have given it this name. The trailing arbutus is the provincial flower of Nova Scotia and the state flower of Massachusetts. James L. Luteyn

Scientific classification. The trailing arbutus is in the heath

family, Ericaceae. Its scientific name is *Epigaea repens*.

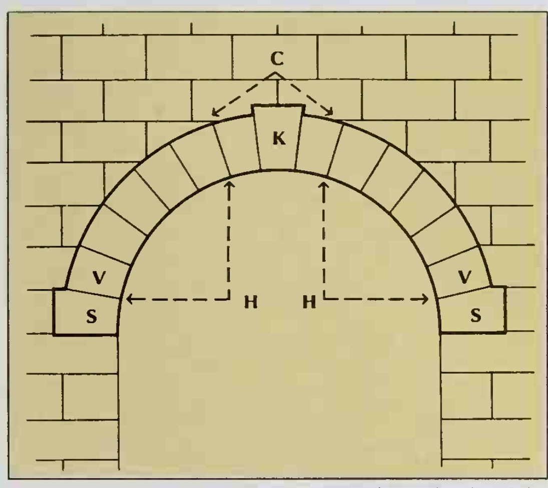
See also Flower (picture: Flowers of woodlands and forests).

Arc, in geometry. See Circle (Parts of a circle).

Arc, Joan of. See Joan of Arc, Saint.

Arc de Triomphe, *ahrk duh tree AWNF,* in Paris is the largest triumphal arch in the world. The arch stands 162 feet (49.5 meters) high. It is known as the *Arch of Triumph* in English. It stands at the western end of the broad avenue called the Champs Élysées. See Paris (picture: The Arc de Triomphe; map: Central Paris).

Emperor Napoleon I commissioned the arch in 1806 as a memorial to his imperial armies. It was designed by architect Jean-François Chalgrin, who patterned it after the triumphal arches of ancient Rome. The arch was left unfinished when Napoleon lost power in 1814. It was completed in 1836. The structure is an example of the Neoclassical style of the late 1700's and early 1800's. The arch is decorated with relief sculpture, notably the group of figures called *La Marseillaise* (1836) by François Rude. The grave of France's Unknown Soldier of World War I lies beneath the arch. Leland M. Roth



Arcadia, *ahr KAY dee uh,* a departments of present-day Greece, was an important region in ancient times. About 100,000 people live in this region of mountains and fertile valleys in the *Peloponnesus* (Greece's southern peninsula). Arcadia was the only part of the Peloponnesus not overrun by Dorians in the 1100's B.C. In the 500's B.C., Arcadia joined the Peloponnesian League, a military alliance of Peloponnesian cities led by Sparta. Arcadian cities were loyal to Sparta until 369 B.C., when they formed their own defensive league. The Arcadian League soon split, but Macedonia and then the Achaean and Aetolian leagues protected Arcadia. John J. Baxevanis

Arcaro, *ahr KAIR oh,* **Eddie** (1916-1997), an American jockey, rode 4,779 winners in 31 years of racing. Arcaro became the first jockey to win the Kentucky Derby five times (see **Kentucky Derby**). He was also the first to win the *Triple Crown* (Kentucky Derby, Preakness, and Belmont Stakes) twice. He won it riding Whirlaway in 1941 and Citation in 1948. Edward Arcaro was born in Newport, Kentucky. He retired in 1962. His purses totaled $30,039,543, a record until 1964. William F. Reed

Arch is a curved structure that supports or strengthens a building. Almost all arches span openings and support weight above them. Others are enclosed in walls.

Most arches are made of stone, brick, concrete, or steel. Arches of stone or brick consist of wedge-shaped blocks called *voussoirs*. During the construction of most such arches, the blocks are supported by a wooden frame. The last block to be inserted is the *keystone,* the center stone at the top. The pressure of each side of the arc against the keystone supports the arch when the frame is removed. In addition, the arch is supported on both sides by masonry or by other arches to keep it from collapsing under the weight above.

The first people to fully utilize the arch were architects of ancient Rome. During the 300's B.C., they began to use semicircular arches to build aqueducts and bridges. Later, they also constructed *triumphal arches* to honor their leaders. Pointed arches were developed during the Middle Ages. Medieval architects arranged arches in rows to form passageways called *arcades*. They also built arched roofs called *vaults*. Arches

WORLD BOOK illustration by Arthur L. Grebetz

An arch is made up of parts that support one another. Wedge-shaped arch stones called *voussoirs* (labeled *V*) make up most of the arch, rising from *springers (S)* to the *keystone (K)* at the top. The *crown (C)* is the highest part of the arch. The *haunches (H)* are the sides of the arch, from the crown to the springers.

Archaea, *ahr KEE uh,* also called *archaebacteria,* are a group of single-celled organisms that make up one of three basic divisions of life. The other two kinds of living organisms are *eukaryotes,* which include animals and plants, and *eubacteria,* which include most of the organisms commonly called bacteria. Eukaryotes have *eukaryotic cells,* or cells with a nucleus, while eubacteria and archaea have *prokaryotic cells,* or cells that lack a nucleus. Scientists had traditionally classified archaea with eubacteria because of their similar cell structures. But beginning in the 1970's, close analyses of their genes revealed that archaea and eubacteria are too different to be grouped together. In many respects, archaea more closely resemble eukaryotes than they do eubacteria.

Archaea rank among the oldest forms of life on earth. Some scientists believe these organisms are similar to the original ancestors of all modern life. Archaea have developed unusual properties. For example, various kinds of archaea can consume acetic acid, hydrogen, or sulfur. Some archaea can even produce the gas methane. Other kinds have developed an unusual form of *photosynthesis,* a process by which they make food. Unlike photosynthesis in plants and bacteria, archaeal photosynthesis does not use the green pigment chlorophyll.

Archaea live in a wide variety of habitats. Many live in such harsh conditions as oil wells, deep-sea *hydrothermal vents* (hot springs), and *anaerobic* (oxygen-free) environments. Other archaea grow in soils and within various living organisms. Cattle, termites, and even people have archaea living harmlessly in their digestive systems. Gary J. Olsen

James Stanfield, National Geographic Society Image Collection

Archaeologists excavate ruins of the ancient city of Ubar in Oman searching for remains of past human activities. Modern archaeology often combines hard work, such as digging with hand tools, with complex technology. These ruins were found in 1981 using radar images obtained from space.

Archaeology

Archaeology, *AHR kee AHL uh jee,* is the scientific study of the remains of past human cultures. Archaeological research is the chief method available for learning about societies that existed before the invention of writing about 5,500 years ago. It also provides an important supplement to our knowledge of ancient societies that left written records.

Archaeologists investigate the lives of early people by studying the cultural remains they left behind. Such remains can include buildings, artwork, tools, or pottery. Archaeologists also examine the context and associations of the remains, which can provide information about how the remains were used. The preserved residues from food items, such as bones and plant parts, can also reveal much about how ancient people lived.

Archaeology in the Americas and in Europe is considered a branch of *anthropology,* the scientific study of human culture. Some archaeological investigations are closely linked to history, though historians mainly study events in the past recorded in written documents.

Archaeologists look for information about how, where, and when cultures developed. Like other social scientists, they search for reasons why major changes have occurred in certain cultures. Some archaeologists try to understand why ancient people stopped hunting and started farming. Others develop theories about what caused people to build cities and to set up trade routes. In addition, some archaeologists look for reasons behind the fall of early civilizations, such as the Roman Empire, or examine why large cities of the Maya were abandoned around A.D. 850.

Thomas R. Hester, the contributor of this article, is Director of the Texas Archeological Research Laboratory and Professor of Anthropology at the University of Texas at Austin.

What archaeologists study

Archaeologists examine any evidence that can help explain how people lived in the past. Such evidence ranges from the ruins of a large city to a few stone flakes left by someone making a stone tool long ago.

The three basic kinds of archaeological evidence are (1) artifacts, (2) features, and (3) ecofacts. *Artifacts* are any objects made by human hands. An artifact can be a pyramid, a point chipped from flint, a ceramic pot, or a variety of other items made from a wide range of materials. *Features* are evidence of past human activities visible as disturbances in the earth. Such disturbances can be produced by people digging pits for storage, building a house or tomb, or constructing canals for irrigation. Unlike artifacts, features cannot be separated from their surroundings. *Ecofacts* are natural objects found with artifacts or features. Ecofacts reveal clues about past environments and how ancient people utilized the resources available to them. For example, charred seeds and animal bones tell archaeologists about the foods of ancient peoples, while preserved pollen can provide evidence about vegetation and climate changes over time.

Any place where archaeological evidence is found is called an *archaeological site.* To understand the behavior of the people who occupied a site, archaeologists must study the relationships among the artifacts, features, and ecofacts found there. For example, American archaeologists discovered flint spearpoints among the bones of extinct, Ice Age buffalo at the Folsom site in

© Superstock

An army of life-sized statues of soldiers and horses form an amazing collection of *artifacts* (objects made by people). The clay figures were found in 1974 in burial pits near Xi'an, China, close to the tomb of Shi Huangdi, who ruled China in the 200's B.C.

New Mexico. These artifacts demonstrated that ancient peoples had reached the New World at least 10,000 years ago.

If objects are buried in the ground, their position in the earth is also of interest to archaeologists. The scientists study the layers of earth and rock in which objects are found to understand the conditions that existed when the objects were placed there. In some places, archaeologists find many levels of deposits called *strata*. The archaeological study of strata, called *stratigraphy*, developed from the study of rock layers in geology.

How archaeologists gather information

Archaeologists use special techniques and equipment to gather archaeological evidence precisely and accurately. They also maintain detailed written records, photographs, maps, and plans of sites because archaeological research actually destroys much of the site.

Locating sites is the first job of the archaeologist. Sites may be aboveground, underground, or underwater. Underwater sites include sunken ships as well as entire towns that have been submerged because of shifts in land or water level.

© Phil Degginger, Bruce Coleman Inc.

The foundation of a Roman bath at Caesarea, near Hadera, Israel, is an example of an archaeological *feature*. Features are evidence of human activities often visible as changes in the earth.

National Museum of Man, Ottawa, Canada

Whale bones, *foreground*, were among the *ecofacts* found in diggings on Bathurst Island in the Canadian Arctic. Such natural objects reveal how ancient people related to their surroundings.

Some large sites are located easily because they are clearly visible or can be traced from descriptions in ancient stories or other historical records. Such sites include the pyramids in Egypt and the ancient city of Athens in Greece. Some less obvious sites have been discovered accidentally by nonarchaeologists. In 1940, for example, four children in search of their dog found the Lascaux Cave in southwestern France, which has prehistoric wall paintings. Many important discoveries have been made by archaeologists who searched tirelessly over many years for a specific site or type of site. Working in this way, an English archaeologist named Howard Carter discovered the treasure-filled tomb of the ancient Egyptian king Tutankhamen in 1922.

Archaeologists use systematic methods to discover sites. The traditional way to find all the sites in a region is through a *foot survey.* In this method, archaeologists space themselves at measured distances and walk in preset directions. Each person looks for archaeological evidence, such as bits of flint or pottery fragments, while walking. Archaeologists use this method when they want to know where sites do not occur as well as where they do. For example, they might use it to confirm that sites in a particular region occur on hilltops but never in valleys.

Archaeologists use a variety of scientific methods to help discover sites that have been covered over by natural forces, such as floods or blowing sand, or obscured by human activities, such as farming. *Remote sensing,* the use of instruments to observe and record information from a distance, is a common technique used by archaeologists. Aerial photography, for example, can reveal variations in vegetation that indicate the presence of an archaeological site. Plants that are taller in one area of a field may be growing over an ancient grave or irrigation ditch. Plants that are shorter in another area may be growing in shallow ground over an ancient building or road. Today, archaeologists may locate sites with *infrared* (heat detecting) imaging or even photographs taken from orbiting satellites. On the ground, remote sensing techniques, such as *ground-penetrating radar,* can reveal buried structures or graves. Even simple metal detectors can be used to detect buried metal artifacts.

Aerofilms Ltd.

Aerial photography can reveal unsuspected sites. The outlines of a royal Celtic monument were discovered in County Meath, Ireland. The monument, called Tara, dates from about 2,000 B.C.

Surveying sites. Archaeologists begin to study a site by describing it and plotting the location on a *topographic map* (map showing surface features). Handheld tools called Global Positioning System (GPS) devices enable archaeologists to determine precise locations through readings obtained from satellites. Archaeologists make detailed notes about the condition of the site and the kinds of evidence visible on its surface. They also take photographs of the site.

Pat Baker, Western Australian Maritime Museum

An underwater site may contain cargo from sunken ships. Such cargo has added to our knowledge of ancient Greek and Roman times. Archaeologists working off the west coast of Australia use a vacuum device to scoop up coins and other small objects, as shown here.

Archaeologists make maps of most sites they find. The type of map drawn depends on the importance of the site, the study's goals, and the amount of time and money available. In some cases, simple maps are made after pacing off distances or using a measuring tape. In other cases, a special instrument called a *transit* is used to survey the site carefully. Today, many archaeologists use a *total data station,* a device utilizing laser and computer technology, to rapidly survey and map a site.

After making a map, the scientists collect artifacts from the surface of the site. They divide the surface into a grid pattern of squares and examine one square at a time. The locations where artifacts are found are recorded on the map. Some surface artifacts can give information about when or how a site was used.

Excavating sites. Archaeologists dig carefully for buried remains in a process called *excavation.* The method of excavation depends partly on the type of site. The archaeologist must use precise techniques and careful observation to determine the context and association of buried artifacts and features. For example, archaeologists working in a cave might divide the floor and the area in front of the cave into square units and then excavate each unit separately. Archaeologists working on a temple platform might dig a trench into the front part of the platform and extend the trench into the ground next to the platform. At large sites, excavation may be limited to certain areas. Other considerations that frequently determine the excavation method include the climate and soil at the site. Today, archaeologists often expose broad areas of a site in a technique called *open area* or *block excavation* so the patterns of an ancient settlement can be detected.

Tools used in excavation range from backhoes and other heavy equipment to shovels and paintbrushes. The most common tool used is the *trowel,* a small, flat, pointed implement often used in bricklaying. A trowel is used to carefully remove earth so that artifacts and features can be found in place, carefully exposed, and documented. In most excavations, archaeologists screen excavated deposits through wire-mesh sieves to recover small artifacts and ecofacts. They also collect soil samples to be analyzed in a laboratory to detect microscopic pollen grains or charred plant remains. Chemical analysis of the soil can also detect hidden evidence of human activities.

Working underwater. Archaeologists who work underwater use many methods adopted from land archaeology. Aerial photography over clear water may reveal the outlines of sunken harbors and towns. A method called *sonar scanning* helps detect underwater objects by the reflection of sound waves. In addition, divers use metal detectors to uncover metal objects. Photographic maps of sites can be made from submarines or by divers carrying underwater cameras. Archaeologists work at underwater sites in submersible decompression chambers. They sometimes use balloons to raise large objects to the surface for further study.

Some underwater sites require extraordinary measures. Archaeologists working in rough waters on the French ship *La Belle,* which had sunk off the Texas coast in the 1700's, exposed the site by building a giant steel enclosure around it. After the ocean water was pumped out, they could begin excavation on the fragile wreck.

Douglas Gann Homol'ovi Research Program, Arizona State Museum

A rendering of an ancient Anasazi ceremonial center called a *kiva* was produced by archaeologists using computer software. Archaeologists often use computers to evaluate information.

Recording and preserving evidence. Archaeologists describe, photograph, and count the objects they find. They group the objects according to type and location. For example, broken pieces of pottery, called *potsherds,* are bagged together by excavation unit and level. This collection then goes to the field laboratory to be cleaned and labeled. Some artifacts, such as knives or spearpoints, should not be washed. Washing removes residues, such as fat or blood, that can be identified through microscopic or chemical analysis. Identification of the residues can indicate how the artifact was used.

At the field laboratory, archaeologists must take special care to preserve objects made of such materials as metal and wood. For example, rust on a metal object must be removed without damaging the surface. Water-soaked wooden objects may crack or lose their shape when exposed to the air. These objects must be kept wet until specialists called *conservators* can preserve them.

How archaeologists interpret findings

Archaeologists follow three basic steps in interpreting the evidence they find: (1) classification, (2) dating, and (3) evaluation.

Classification. Archaeologists can interpret their findings only if they can detect patterns of distribution of artifacts in space or through time. To find these patterns, archaeologists must first classify artifacts into groups of similar objects.

Typology is the most common approach in classification. Artifacts are usually first sorted into groups based on their shape, known as *morphological types.* If the shape and manufacturing methods found among morphological types are distinctive during certain periods, they may represent *temporal types.* Archaeologists use temporal types to construct a sequence that reflects changes in the style or manufacture of artifacts over time. A sequence of different temporal types from a region reflects cultural change through the years. More

detailed studies, such as the microscopic examination of a flint blade or the analysis of residues on a potsherd, can lead to the recognition of *functional types*. Some types are defined by the archaeologist, while other typological classifications actually reveal the designs and shapes intentionally developed by ancient peoples.

Dating of archaeological objects is called *archaeometry*. The methods of archaeometry are divided into two major types: (1) *relative dating* and (2) *absolute dating*.

Relative dating gives information about the age of an object in relation to other objects. Thus, relative dating methods produce only comparisons, not actual dates. For example, archaeologists can determine the relative ages of bones found at a site by measuring their fluorine content. Fluorine from underground water gradually replaces other elements in bones, and so older bones contain more fluorine.

Christopher Cunningham, Stratford Hall Plantation

A reconstructed slave cabin stands at Stratford Hall, the birthplace of Robert E. Lee in Virginia. Historical archaeologists work with historians and architects to re-create such historic buildings

Absolute dating determines the age of an object in years. There are many absolute dating methods. The method used in a specific case depends mainly on the type of object being dated.

The most widely used dating method is *radiocarbon dating*. This method requires *organic material*—that is, something that was once living, such as plant parts, charcoal from cooking pits, bone, or shells. Two types of radiocarbon dating are available to archaeologists today. *Traditional* radiocarbon dating is less expensive to perform but it requires several grams of organic material. *Accelerator mass spectrometry* dating is used when only a small amount of organic material can be recovered from a site, or if only a tiny sample can be removed from a fragile artifact. See **Radiocarbon**.

Other absolute dating techniques have more narrow applications. *Potassium-argon dating* is used mainly in Africa to determine the age of rocks associated with fossils of early human ancestors. Other techniques, such as *electron spin resonance, uranium-series dating,* and *obsidian-hydration dating,* are used in special circumstances or when radiocarbon dating is not possible.

The best-known method for dating wood is called *dendrochronology*. This technique is used mainly in the southwestern United States. It involves counting the yearly growth rings on cross sections of cut trees used to construct ancient *pueblos* (houses). Archaeologists match tree ring patterns with overlapping patterns to a reference sample that extends back at least 8,000 years.

Evaluation. Archaeologists evaluate artifacts and features to learn such information as how and where the objects were made and used. In some cases, the scientists learn by direct experimentation. *Flintknapping* (chipping stone to make a tool) is one widely used form of experimentation. Many archaeologists are skilled at producing exact duplicates of the flint tools found in archaeological sites. Flintknapping helps archaeologists

Christopher Cunningham, Stratford Hall Plantation

Historical archaeologists often study the everyday lives of people in the recent past not recorded in historical documents. These archaeologists have uncovered evidence of a small building and other articles left by former residents at Stratford Hall near Montross, Virginia. The statesman Richard Henry Lee and the military leader Robert E. Lee were born at Stratford Hall, a large plantation built between 1730 and 1738.

understand ancient tool manufacturing techniques and interpret the broken artifacts and flint chips found in excavations. Artifacts and features can also help explain the social lives of ancient people. For example, the size of houses can show how many people lived in one household. The number and value of objects found in graves can indicate differences in social class.

The evaluation of ecofacts reveals such information as what food people ate and whether they grew crops or gathered wild plants. Ecofacts can even explain ancient migration patterns. A seed of grain not native to the area where it is found may reveal how and when eating habits spread from one place to another.

Archaeologists evaluate evidence with the help of specialists from other fields. Zoologists help identify animal bones and butchering techniques. Botanists analyze seeds to learn about ancient agricultural practices. Such specialists as geologists, architects, and engineers also work with archaeologists.

Computers are extremely valuable in evaluating archaeological information. Archaeologists use computer software to produce site maps, plot the distribution artifact types throughout a site, and perform the many statistical analyses necessary to interpret the huge numbers of artifacts and ecofacts recovered in an excavation.

History

Beginnings. The idea of studying the past through ancient objects has developed gradually. But the most intense interest has occurred in the past 200 years. During the 1700's, some wealthy Europeans began to study and collect art objects from the times of ancient Greece and Rome. This interest in classical art is called *antiquarianism.* These first diggers looked only for treasures and threw away ordinary objects.

Also during the 1700's, European scholars began to debate how long human beings had lived on the earth. Their interest resulted partly from discoveries of primitive stone tools together with the bones of extinct animals. These scholars also knew about the huge mounds and ruined cities in the Americas that pointed to ancient human life there. They realized that human beings had a prehistoric past, but they could not decide when and where this past had begun.

The 1800's brought a more scientific approach to the study of the past. The great length of human prehistory became widely accepted due to advances in geology and biology. By the early 1800's, geologists had determined that rock formation resulted from extremely slow processes, such as erosion and volcanic activity. This view, known as *uniformitarianism,* led most scholars to believe that the earth was much older than previously thought. Then, in 1859, the British biologist Charles R. Darwin proposed the theory of biological evolution in his book *The Origin of Species.* This theory suggested that human beings, like other animals and the earth itself, had developed slowly over a vast time.

By the mid-1800's, archaeology had become a separate field of study, and evidence of human prehistory was accumulating rapidly. Important discoveries included prehistoric lake dwellings in Switzerland, ancient cave paintings in France and Spain, and part of a prehistoric human skull found in Germany. In the late 1800's, archaeologists began to use techniques of excavation that made it possible to determine sequences of cultural development. In an excavation at Naqada, near Qus, Egypt, the British scholar Sir Flinders Petrie became one of the first diggers to look carefully for all remains, not just for treasures. Others who undertook major excavations at that time included the British nobleman Sir Austen Henry Layard, at Nineveh in what is now Iraq, and the German businessman Heinrich Schliemann, at Troy in what is now Turkey.

European archaeologists of the late 1800's focused their studies on the ancient European and Middle Eastern civilizations described by classical and Biblical authors. American archaeologists, however, could find almost no written records of the civilizations they studied. Partly for this reason, they turned to anthropology for methods of interpreting their discoveries. For example, they studied artifacts produced by contemporary American Indians to help interpret objects from past societies.

The 1900's. The scope of archaeology expanded greatly during the 1900's. Archaeologists began to explore the past civilizations of Central and South America, China, Japan, Southeast Asia, and other areas. By the early 1900's, archaeologists were using stratigraphy to date their finds. During the mid-1900's, new techniques made dating much easier and more accurate. The most significant of these techniques was radiocarbon dating, developed in the 1940's by an American chemist named Willard F. Libby.

Great advances in underwater archaeology also occurred during the mid-1900's. Previously, underwater excavation had been both difficult and expensive. The aqualung and other diving devices invented during the 1940's enabled divers to move more freely.

Beginning in the 1970's, space satellites began to provide valuable sources of data. Photographs taken from satellites helped locate archaeological sites. In 1995, Global Positioning System (GPS) satellites became fully

The tomb of King Tutankhamen of Egypt was discovered in 1922 by the English archaeologist Howard Carter. Carter, *left,* and his sponsor, Lord Carnarvon, stand at the tomb's entrance.

Important dates in archaeology

1797 British geologist John Frere found flint tools at Hoxne, England, and reported that they belonged to a period "beyond that of the present world."
1837 Christian J. Thomsen, a Danish curator, proposed that the history of humankind, before written records began, could be divided into Stone, Bronze, and Iron ages.
1853-1854 A drought revealed Swiss lake villages dating back at least 5,000 years.
1870 Heinrich Schliemann, a German businessman, began excavations on the site of Troy in what is now Turkey.
1879 Prehistoric wallpaintings were found in a cave at Altamira, Spain.
1884 French archaeologist Marcel-Auguste Dieulafoy uncovered the palace of Persian King Darius I in what is now Iran.
1900 British archaeologist Arthur J. Evans began excavating Knossos, capital of the Minoan civilization of Crete.
1922 Howard Carter of the United Kingdom created worldwide interest in archaeology after finding King Tutankhamen's tomb in Egypt.
1925 Flint points found at Folsom, New Mexico, showed that people lived in Ice Age North America more than 10,000 years ago.
1952 British archaeologist Kathleen Mary Kenyon led excavations at Jericho, Jordan, that proved it to be one of the oldest known communities.
1977-1985 Excavations by American archaeologist Thomas D. Dillehay at Monte Verde, Chile, revealed the earliest known occupation of the New World, more than 12,000 years old.
1991 Hikers in the Alps discovered the frozen, preserved body of a man who lived more than 5,000 years ago. Nicknamed Ötzi, this accidental find provided archaeologists with many new insights into pre-Bronze Age.

operational. The GPS satellites produce signals that can be used to calculate exact locations on the earth (see **Global Positioning System**).

Archaeology today. A major concern among archaeologists today is the preservation of archaeological sites that have not yet been studied. Many such sites are threatened by construction projects, the expansion of agriculture, and other types of development, or by theft. Several countries, including the United States, have enacted laws that require government agencies to identify and preserve places that might be of historic or archaeological importance. Today, governments and private consulting businesses employ many archaeologists to survey, excavate, and protect endangered sites in a process called *cultural resource management.*

Another major concern is protecting the rights of local peoples whose ancestors left the remains unearthed by archaeologists. Many local peoples argue that the skeletal remains of their ancestors deserve a proper burial and should not be considered specimens for research. They also say that many artifacts were sacred objects used for religious purposes and should be treated with reverence. In the United States, the Native American Graves Protection and Repatriation Act of 1990 deals with the ownership of remains and artifacts. The law requires archaeologists to consult with Native American tribes when ancient burials are found in excavations on public lands or at sites where federal funds or permits have been issued. If the archaeologists find human remains or artifacts and a tribe can prove that it has a valid claim to the items, the scientists must return them to the tribe. Australia, New Zealand, and other countries have similar laws protecting the grave sites of local peoples.

On an international scale, archaeologists seek to halt the illegal sale of archaeological objects. They urge developed nations to enact and enforce laws to prohibit the import of ancient objects unless an export certificate has been obtained from the country of origin.

Careers in archaeology

Most careers in archaeology require a master's or doctoral degree. In college, most students who wish to become archaeologists major in anthropology but also take courses in history, languages, biology, computer science, statistics, and geology. In addition, their studies should include experience in excavation. In graduate school, students generally select a geographic area that becomes their research specialty.

Archaeologists are employed in three main fields: (1) academic, (2) museum work, and (3) government service. Most archaeologists who teach at colleges and universities also carry out research and publish their findings. Archaeologists who work in museums conduct research, publish articles, preserve and restore ancient objects, and use those objects to educate the public. Today, the largest number of archaeologists have jobs in the field of cultural resource management. They often work directly for a government agency or for a private business that is hired by the government or by other private companies. Thomas R. Hester

Questions

What are the main steps in surveying an archaeological site?
How do archaeologists use aerial photography?
Why do archaeologists classify the artifacts they find?
How do archaeologists determine the age of remains through radiocarbon dating?
In what ways do other scientists help archaeologists evaluate their findings?
What are *artifacts, features,* and *ecofacts?*
What tools do archaeologists use in excavation?
What are the three main fields in which archaeologists work?
How did advances in geology and biology contribute to the development of archaeology?

Archaeopteryx, *AHR kee AHP tuhr ihks,* is the name of a *genus* (group) of feathered animals that lived about 140 million years ago, during the late Jurassic Period. These crow-sized creatures had a reptilelike skeleton closely resembling that of a small dinosaur. But they also had fully developed feathers and birdlike wings. As a result, most scientists classify *Archaeopteryx* as birds. The first *Archaeopteryx* fossils were discovered during the 1860's in Bavaria, a state in Germany. These fossils provided the first solid evidence that birds descended from reptiles.

Unlike modern birds, *Archaeopteryx* had teeth; a long, reptilelike tail lined with feathers; and three "fingers" with claws on its wings. Scientists believe that the animal used its claws to climb trees. *Archaeopteryx* was most likely an excellent glider. The animal could probably fly, though scientists do not know how well. The word *Archaeopteryx* is Greek for *ancient wing.*

Archerfish is any of six species of large-eyed fish that can shoot drops of water from their mouth into the air with force and accuracy. Archerfish are found in southeastern Asia from India to Indonesia and the Philippines, and in Australia. They live in fresh or slightly salty water, often among the roots of mangrove trees. They grow as long as 16 inches (41 centimeters), but most are about 6 inches (15 centimeters) long.

An archerfish shoots water drops by squeezing its gill covers and forcing water forward along a groove located within the bones of the roof of its mouth. It can shoot water more than 3 feet (90 centimeters) into the air. Archerfish aim at insects on the stems and leaves of plants hanging over the water surface. They also shoot at spiders in webs above the water. When hit, the insects or spiders fall to the water, where the archerfish eats them. John E. McCosker

WORLD BOOK illustration by John F. Eggert

An archerfish hunts insects at the water surface.

Scientific classification. Archerfish belong to the archerfish family, Toxotidae. The scientific name for the best-known species is *Toxotes jaculatrix.*

See Fish (picture: An archerfish).

Archery is the sport of shooting with a bow and arrow. Archers may participate in several forms of the sport. The most popular versions are *bow hunting, target archery, field archery, indoor archery,* and *flight archery.* In bow hunting, the archer hunts game with a bow and arrow. In target, field, and indoor archery, archers compete in shooting at targets. In flight archery, competitors shoot for distance.

Millions of people take part in archery. The sport is especially popular in schools and summer camps. All the states and most provinces in the United States and Canada have special hunting seasons for archers, who shoot such animals as bear, deer, and rabbits. Some archers shoot fish in the shallow waters of lakes and streams. Archers participate in international archery competitions. In addition, archery is an event of the Summer Olympic Games.

Archery equipment

Bows. Three main kinds of bows are used in archery —the *recurve bow,* the *compound bow,* and the *longbow.* The recurve bow, the most common type used by target archers, has tips that curve away from the archer. A compound bow has a system of two cables and from two to six pulleys built into it. The cables and pulleys make this kind of bow easier to *draw* (pull back) than other types. Compound bows are popular with bow

hunters and field archers, but they may not be used in Olympic archery competition. The longbow, once the most popular type of bow, is now used only by a small number of archers. An unstrung longbow looks somewhat like a straight line.

Most bows are made of carbon-reinforced plastics or wood. The core consists of several layers of wood that have been *laminated* (glued together). Some bows can be separated into two or three pieces for carrying or storage. They are commonly called "take-down" bows.

Bowstrings are made of plastics, notably Dacron or polyethylene cord, and have a wrapping of nylon thread opposite the handle of the bow. This wrapping protects the string at the *nocking point,* the place where the notch of the arrow fits. Each end of the string has a loop that is used in stringing the bow. In recurve bows and longbows, the loop fits into a notch at each tip of the bow. In compound bows, the loop is attached to one of the two cables.

The amount of pull required to bring a 28-inch (71-centimeter) arrow to full draw is called the *draw weight* of the bow. For example, a 40-pound (18-kilogram) bow requires 40 pounds of force to draw a 28-inch arrow. Some bows have a weight of more than 60 pounds (27 kilograms). A beginning archer should use a bow of 30 pounds (14 kilograms) or less.

Bows vary in length, depending on their use. Archers also choose a bow that is comfortable for their draw length. Many recurve target archers use bows 68 to 70 inches (173 to 180 centimeters) long. Compound bows average about 45 inches (114 centimeters) in length.

Arrows are made of carbon, aluminum, fiberglass, or wood. Target archers prefer lightweight carbon composite or aluminum arrows, which travel especially fast and accurately. Hunters and other archers who sometimes must shoot on rough land generally use aluminum arrows, which can withstand rough treatment. Beginners should shoot with aluminum or wooden arrows.

All arrows have three main parts—the *point,* which in most cases is made of metal; the *shaft,* and the *nock,* which attaches to the string. Points vary in shape and size. Bow hunters use points that have blades with two or more cutting edges. Target and field archers use a conical, bullet-shaped point. The nock has a notch for the bowstring. Three or four *vanes* (feathers) on the shaft help provide accuracy in shooting. An arrow may be *fletched* (feathered) with plastic vanes or turkey feathers.

Arrow length varies from about 24 to 32 inches (61 to 81 centimeters). An archer can determine the proper length to use by holding an arrow perpendicular to the chest and extending the other arm straight out. The arrow should reach just beyond the fingertips.

Most archers carry their arrows in a holder called a *quiver.* The quiver may be attached to the bow or a belt, or placed on the ground.

Archery safety

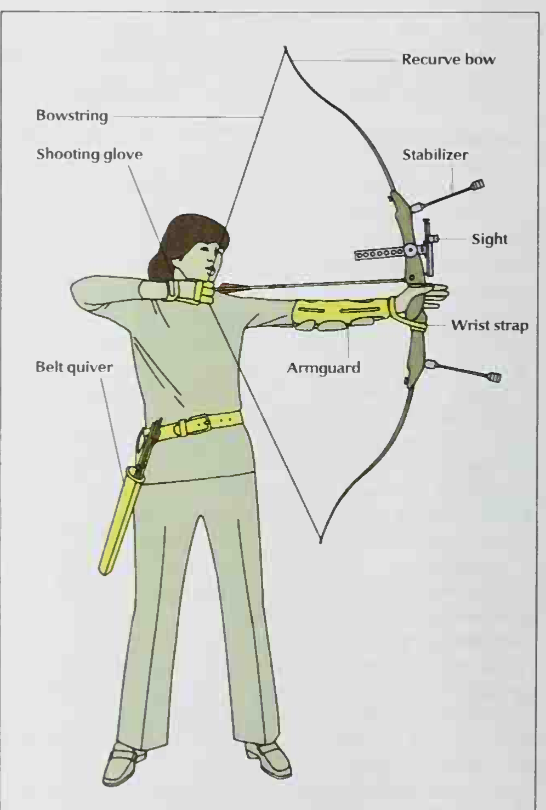
Archers should observe the following rules to avoid injuring themselves or others:

Never point a drawn bow at any object or animal you do not want to hit.

Never shoot an arrow unless the area is free of people or animals.

Never shoot an arrow straight up.

Keep all archery equipment in good condition.



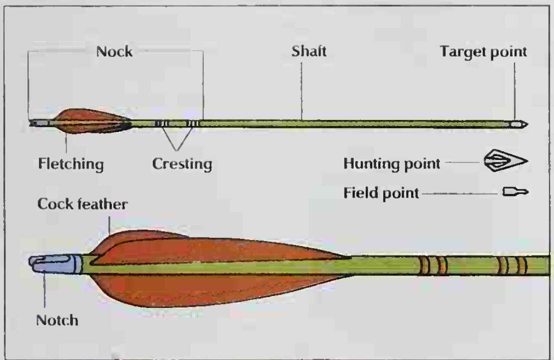
Other equipment includes an armguard made of leather or plastic. The guard is worn on the forearm of the hand that holds the bow. It protects the forearm when the bowstring snaps back after being released. Archers also wear a *shooting glove* or a leather *tab* to protect the fingers that draw the bowstring.

Many bows are equipped with a *sight* used for aiming. Sights range from simple metal pins to telescopic eyepieces. Most target archers use one or two composite or metal rods called *stabilizers* to reduce the vibrations in a bow after the bowstring is released. These rods, manufactured in various lengths and weights, are usually attached to the back of the bow handle.

Archery competition

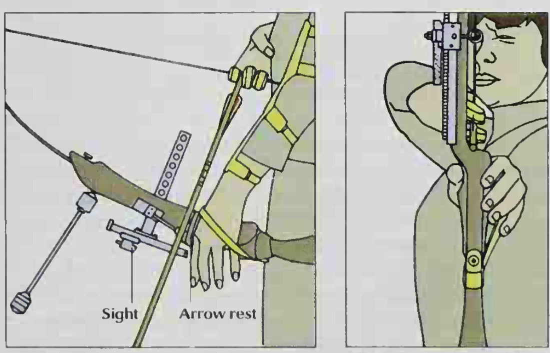
Archers take part in many types of competition. The most popular contests include those in *target archery, field archery, flight archery, indoor archery,* and *3-D archery.*

Target archery is the most common form of competition. The archers shoot down a long course at woven straw or foam mats called *buttresses.* The buttresses are covered with a target that is divided into five colored circles. A thin line divides every color into two rings, each of which counts for a different score. The colors and their value in points are: gold, 10 and 9; red, 8 and 7; blue, 6 and 5; black, 4 and 3; and white, 2 and 1.



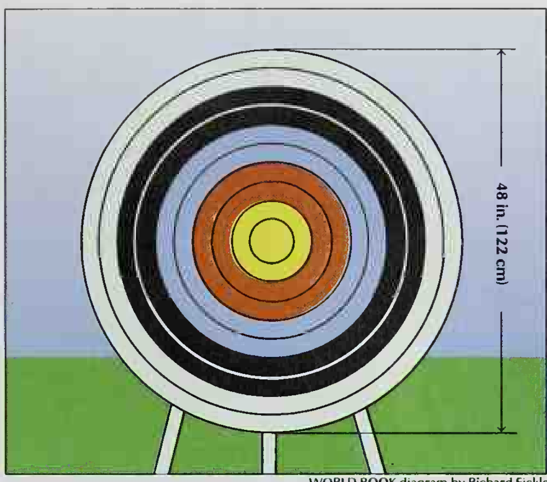
WORLD BOOK illustration by David Cunningham

Archery equipment includes accessories that help an archer shoot better and more comfortably. Most target archers use recurve bows equipped with a *sight* and one or two *stabilizers.*



The number of shots allowed each archer is called a *round.* In the United States, the National Archery Association has established many kinds of rounds for men, women, and children. Olympic archery competition and all international tournaments are held under the rules of the International Archery Federation. These rules call for men and women to shoot from varying distances, 90 meters (98 yards) being the maximum distance for men and 70 meters (77 yards) the maximum for women. The types of rounds that the archers shoot vary according to the level of competition, such as the World Championships or the Olympic Games. In the 90-, 70-, and 60-meter (66-yard) distances, and in all competition in the United States, archers shoot at targets 122 centimeters (48 inches) in diameter. The 50-and 30-meter (55- and 33-yard) distances use a target 80 centimeters (31 inches) in diameter.

Field archery involves walking across a course set out in an open field or wooded area shooting at buttresses from various distances. The basic contest, called a *field round,* consists of a course with 14 buttresses. They are covered with black-and-white targets that measure 15, 30, 45, or 60 centimeters (6, 12, 18, or 24 inches) in diameter. Each target has three circular scoring rings—a black center ring worth 5 points, a white middle ring, 4; and a black outer ring, 3. The archers shoot two rounds of four arrows each at every target.



WORLD BOOK diagram by Richard Fickle

The main parts of an arrow are the point, the shaft, and the nock. The nock includes a notch for the bowstring and three or four feathers that help provide shooting accuracy.

WORLD BOOK illustration by David Cunningham

Notching an arrow, a process called *nocking, left,* is the first step in drawing the bowstring. The archer grasps the string with three fingers. Many archers aim by using a sight, *right.*

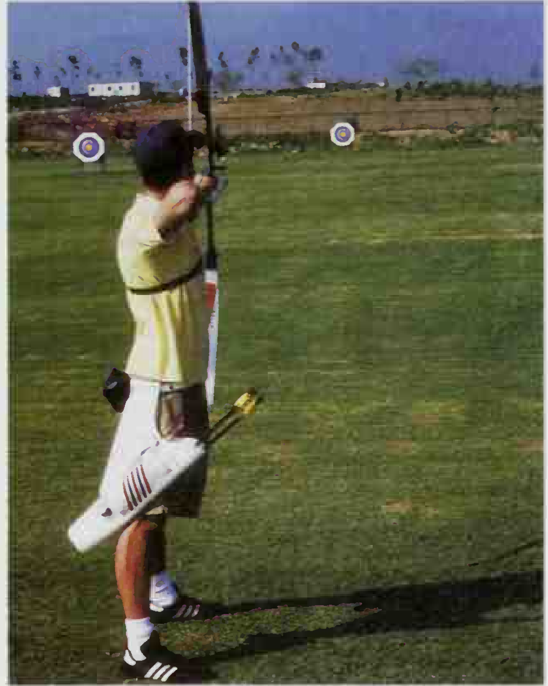
WORLD BOOK diagram by Richard Fickle

The target used in target archery competition in the United States has 10 scoring rings and 5 colored circles. An archer scores 10 points by hitting the bull's-eye.

The distance to the targets ranges from about 6 to 72 meters (7 to 80 yards).

Flight archery is competition in which archers try only for distance, not accuracy. They use special bows with a draw weight of up to 200 pounds (91 kilograms), and small, lightweight arrows. In regular flight archery, the archers shoot while standing. In *freestyle* flight archery, they lie on their back with the bow strapped to their feet. They use both hands to draw the bow. An archer can shoot farther than 700 yards (640 meters).

Indoor archery involves shooting at a distance of 18 meters (20 yards). The archer generally shoots 12 rounds of five arrows or 10 rounds of six arrows. Many archers compete indoors during the winter months to keep in shape for outdoor competitions or hunting.



3-D archery consists of shooting arrows at lifelike foam models of game animals, such as deer and elk. The archer must correctly estimate the distance of the target. The model animal has scoring rings that can only be seen from a short distance. Because 3-D archery has many of the same challenges as hunting, it is a popular off-season activity for bow hunters.

History

Prehistoric people invented the bow and arrow thousands of years ago. The weapon revolutionized early hunting methods by enabling people to kill animals from a distance. The ancient Egyptians were the first people known to use the bow and arrow extensively. They used the weapon for hunting and in war as early as 5000 B.C. Other early peoples who used bows and arrows included the Assyrians and the Persians.

By the A.D. 900's, the Turks had developed advanced archery equipment. They used laminated bows made of a combination of wood and animal horns and tendons. The tips of their bows curved outward like modern recurve bows. By the 1100's, the crossbow had become a popular weapon in Europe (see Crossbow).

The *longbow* ranked as the chief weapon of the English Army when the Hundred Years' War began in 1337. In 1346, in the Battle of Crécy, 7,000 English archers

© Jason Vaccarello, National Archery Association

Target archery is the most common type of archery contest. An archer tries to score points by shooting arrows from several distances at a circular target divided into 10 scoring rings.

routed a much larger French force that included over 1,000 armor-clad knights. In 1415, in the Battle of Agincourt, about 6,000 English troops with longbows defeated a French force of about 20,000 to 30,000.

By about 1500, firearms had replaced the bow and arrow as the chief weapon of English infantry. In the 1540's, English author Roger Ascham wrote *Toxophilus,* the first book to describe the proper way to shoot a bow and arrow. The Royal Toxophilite Society was set up in England in 1781 to promote archery as a sport.

The first archery organization in the United States was the United Bowmen of Philadelphia, founded in 1828. The National Archery Association was established in 1879 and held its first tournament that year. In 1931, the International Archery Federation (FITA) was founded to conduct international tournaments. The National Field Archery Association was organized in 1939 by a group of American hunters. In 1969, FITA added field archery to the events in world championship archery competition. In 1991, the federation added indoor archery.

Compound bows came into use during the 1970's. They soon gained wide popularity because they are so easy to draw and hold. Critically reviewed by the National Archery Association of the United States

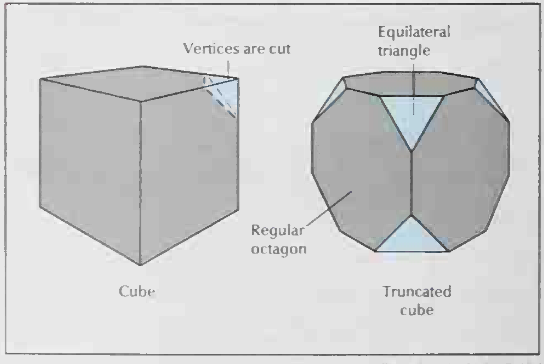
Arches National Park lies near Moab in southeastern Utah (see Utah [physical map]). Its unusual sandstone rock formations look like huge arches, windows, and towers. Landscape Arch is one of the world's longest natural arches. It has a 291-foot (89-meter) span. The park became a national monument in 1929 and a national park in 1971. See National Park System (table: National parks). Critically reviewed by the National Park Service



Archimedean screw, *AHR kuh MEE dee uhn,* is a device for raising water. It consists of a screw or an arrangement of blades sealed to the inside of a cylinder. The lower end is placed in the water. The upper end has a crank that turns the cylinder. The threads of the screw or the blades slowly raise the water until it flows out the upper end. This device was used in the Nile Valley for draining and irrigating land. Some scholars believe it was invented by the ancient Greek mathematician Archimedes. Delmar D. Fangmeier

See also Invention (Ancient Greece).

Archimedean solid, *AHR kuh MEE dee uhn,* is any of 13 solid figures. These figures were first described by the ancient Greek mathematician Archimedes.

Archimedean solids are *semiregular convex polyhedrons* (see Polyhedron). The *faces* (surfaces) of any Archimedean solid represent more than one kind of regular polygon. However, all the *polyhedral angles* are identical. A polyhedral angle is a figure formed at a *vertex* (point) where three or more faces meet.

One example of an Archimedean solid is the *truncated cube.* This figure is formed when each corner of a cube is *truncated* (cut off) at the same angle. An equilateral triangle then replaces each corner and an octagon replaces each square face of the cube. Thus, a truncated cube has six faces that are octagons, and eight faces that are equilateral triangles. Each vertex is the corner of one triangle and two octagons. John K. Beem

WORLD BOOK illustrations by Zorica Dabich

A truncated cube is a type of Archimedean solid. It is formed when the eight vertices of a cube are cut off at the same angle, leaving an equilateral triangle in place of each vertex. Each square face of the original cube becomes a regular octagon.

Archimedes, *AHR kuh MEE deez* (287?-212 B.C.), was the most original and profound mathematician of ancient times. Archimedes, a Greek, was also a physicist and a mechanical engineer. In the ancient world, he was best known as an inventor. His surviving writings rank among the masterpieces of scientific literature, especially *On the Sphere and Cylinder.*

WORLD BOOK illustration by Oxford Illustrators Limited

The Archimedean screw raises water as the handle is turned. The water is carried upward within the spiral chambers as the screw revolves. The water comes out of the screw's upper end.

His life. Archimedes was born in Syracuse, the largest Greek settlement in Sicily. He probably went to study in Alexandria, Egypt, then the chief center of Greek learning. There, Archimedes studied with disciples of Euclid, a famous Greek mathematician. Archimedes spent the rest of his life in Syracuse. When the Romans captured Syracuse, the Roman commander Marcellus ordered that citizens of Syracuse be left unharmed. However, according to one story, Archimedes was killed by a soldier while working on a geometry problem.

His discoveries. Archimedes proved the law of the lever and invented the compound pulley. With these machines, it is possible to move a great weight with a small force. Archimedes reportedly once boasted to Hiero, king of Syracuse: "Give me a place to stand on, and I will move the entire earth." He was referring to the way levers and pulleys can help people move objects many times their own size. The king challenged him to prove his boast. Archimedes is said to have used a system of pulleys to move a ship fully loaded with passengers and freight (see **Lever**; **Pulley**). In his investigations of force and motion, Archimedes also discovered that every object has a *center of gravity.* This is a single point at which the force of gravity appears to act on the object (see **Gravity, Center of**).

Archimedes did much of his work for King Hiero. In one famous story, the king suspected that a goldsmith had not made a new crown of pure gold, but had mixed in some less costly silver. The king asked Archimedes to find out if the goldsmith had cheated.

Archimedes found the answer to this problem while taking a bath. His solution rested on *volume* (the amount of space occupied by an object). Archimedes noticed that water spilled out of the bath as he placed his body into it. By measuring the amount of water his body displaced, he could measure its volume. Archimedes was so excited when he found the answer that he ran into the street without dressing, shouting "Eureka!" (I have found it!). Archimedes compared the amount of water displaced by the crown to the amount of water displaced by an equal weight of pure gold. The crown displaced more water, and so it was not pure gold. The goldsmith had cheated.

Archimedes discovered other basic laws of *hydrostatics,* the branch of physics that deals with liquids at rest. One of the major laws, called *Archimedes' principle,* describes *buoyancy.* Buoyancy is the loss in weight an object seems to undergo when placed in a liquid, as compared to its weight in air. Archimedes' principle states that an object fully or partly immersed in a liquid is buoyed upward by a force equal to the weight of the liquid displaced by that object. From this principle, he concluded that a floating object displaces an amount of liquid equal to its own weight.

His inventions. Archimedes is credited with inventing a device used in ancient Egypt to drain and irrigate the land in the Nile Valley. This device, known as the Archimedean screw, is still used today. Archimedes also invented devices used to defend Syracuse against Roman attacks. These devices included cranes that could pull Roman ships out of the water and twirl them around, and *catapults,* weapons that shot heavy rocks at the enemy. Some writers of ancient times reported that Archimedes designed a system of mirrors that reflected the sun's rays to set Roman ships on fire. However, historians doubt if the fire mirrors ever existed.

His mathematics. Archimedes made significant contributions to theoretical mathematics. He extended the *method of exhaustion,* a way of determining the area of figures bounded by curved lines or surfaces. The method of exhaustion foreshadowed a form of higher mathematics called *calculus.* Archimedes used this method to make more precise estimates than any before of the value of *pi,* the ratio of a circle's circumference to its diameter. He showed that the value of pi is greater than $3\frac{10}{71}$ but less than $3\frac{1}{7}$. Archimedes felt that his greatest discoveries were the formulas for the surface and volume of a sphere. He also devised a system of notation for expressing numbers far larger than those represented in the alphabetic numeration system then used.

Ronald S. Calinger

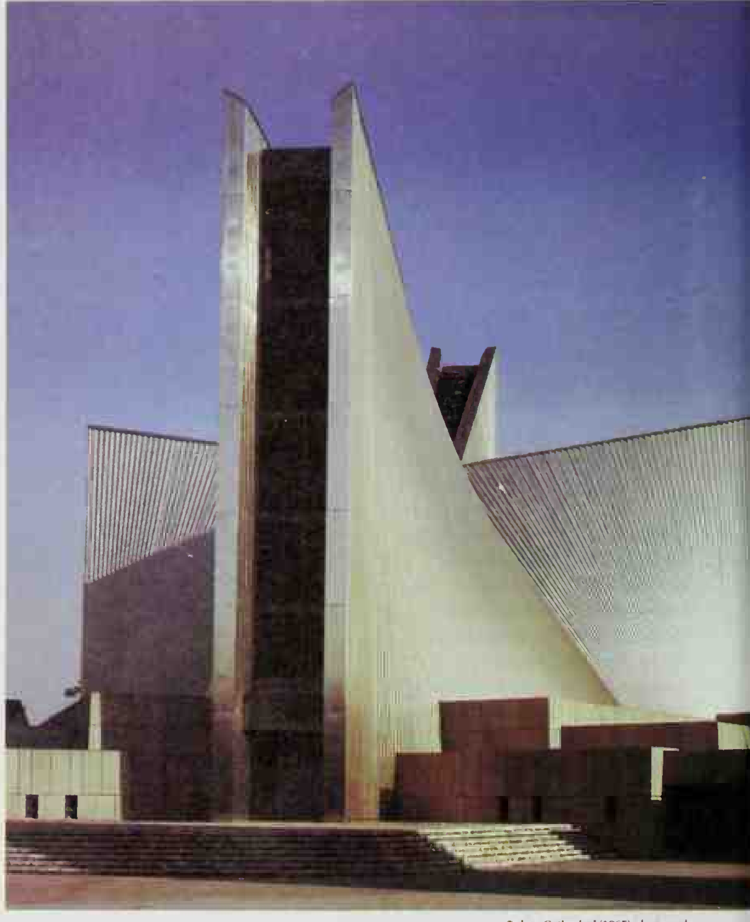
Archipelago, *AHR kuh PEHL uh goh,* is a Greek word that means *chief sea.* It now applies to any broad expanse of water containing islands, and is often used for the islands themselves. The best-known examples are the Malay and Lofoten archipelagos. See also **Island**; **Pacific Islands**. Peter P. Sakalowsky



Archipenko, *AHR kuh PEHNG koh,* **Alexander** (1887-1964), was a pioneer cubist sculptor. He was one of the first sculptors to show that spaces can be as important to a work as the solids. This view was a basic element in Archipenko's style throughout his career. His use of solids and hollows influenced many modern sculptors. Archipenko's forms are *concave* (curving inward) and *convex* (curving outward) with angular shapes and openings. Typical examples include *Seated Woman* (1916) and *Dual* (1955). He was also one of the first artists to adapt the new technique of *collage* to sculpture, mixing a wide variety of materials (see **Collage**).

Archipenko was born in Kiev, in the Ukraine. He moved to the United States in 1923 and became a citizen in 1928. He founded art schools in Europe and America, and taught at several U.S. universities. Joseph F. Lamb

The Tokyo Cathedral in Japan shows the influence of modern Western architecture in the structure's streamlined design and white concrete walls.

Architecture

Architecture is a term with several meanings, all related to buildings. It may refer to the art and science of building, practiced by artists called architects. Or, *architecture* may mean the buildings themselves. The term also has a historical meaning referring either to the building style of a particular culture or to an artistic movement. For example, we speak of Greek architecture or Gothic architecture.

Architects create many kinds of structures. For instance, they design houses, schools, hotels, hospitals, stadiums, factories, office buildings, theaters, and houses of worship. Architects also design monuments dedicated to the memory of important events and people. The beauty of a city or town is largely determined by the quality of its architecture.

G. L. Hersey, the contributor of this article, is Professor of the History of Art at Yale University. Marvin Trachtenberg, the critical reviewer of this article, is Edith Kitzmiller Professor at the Institute of Fine Arts at New York University.

Although architecture has artistic qualities, it must also satisfy a number of important practical requirements. For example, an architect may design an office building that looks beautiful. But if people cannot work comfortably and efficiently in it, the building fails architecturally.

There are unique features of architecture that set it apart from other arts. In most cases, painters, writers, composers, and other artists create their works and then try to sell them. But a building may cost thousands or millions of dollars to construct. In nearly all instances, architects must have a buyer for their work before they create it. For example, rarely can an architect design an office building, afford to have it constructed, and then try to find someone who will buy it.

Unlike some other artists, architects must work with other people to produce their designs. Novelists, for example, can create their stories alone from their own in-

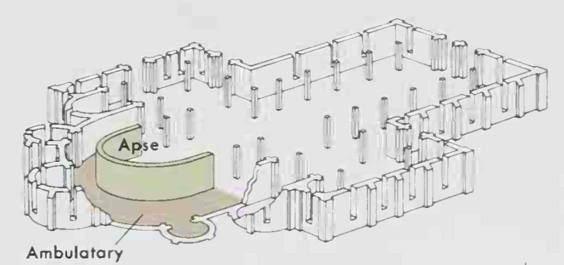
spiration. But almost all architects design a building for a client and must observe the client's wishes and needs. Within the limits of those wishes and needs, architects can make their personal artistic contributions.

Architects work closely with the client throughout the development of a building. They decide how best to fulfill the client's requirements and give advice on probable costs. They make drawings and models that show how the building will look after it is completed. They also work with the many different types of contractors who actually build the structure. Architects supervise the construction and, in many cases, receive a percentage of the construction budget as their fee.

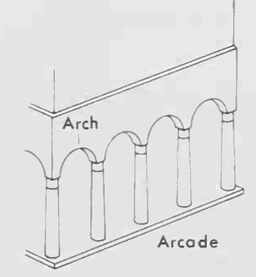
Architecture is one of the oldest art forms. It dates from prehistoric times and is found in almost all societies. A society's architecture reflects the values and ideals of its people. For example, the ancient Greeks stressed discipline and harmony in life, and so they created an architectural style that was balanced and orderly. The beautifully proportioned Greek temple reflects this emphasis on harmony. The Middle Ages was a period of deep religious faith in Europe. Architects designed majestic cathedrals with *vaults* (arched ceilings) and towers that seemed to soar toward heaven. Like the Greek temple, the medieval cathedral was intended to inspire a mood of reverence among worshipers.



Architects rank among the greatest figures in the history of art. But many architectural masterpieces were created by skilled builders who probably did not consider themselves artists and had no idea that they had created buildings which critics later would praise as important works of architecture. During the 1600's, for example, colonists in New England built houses that were not primarily designed to be beautiful. Some of these houses have been preserved and are admired today for their skilled carpentry and handsome outlines.

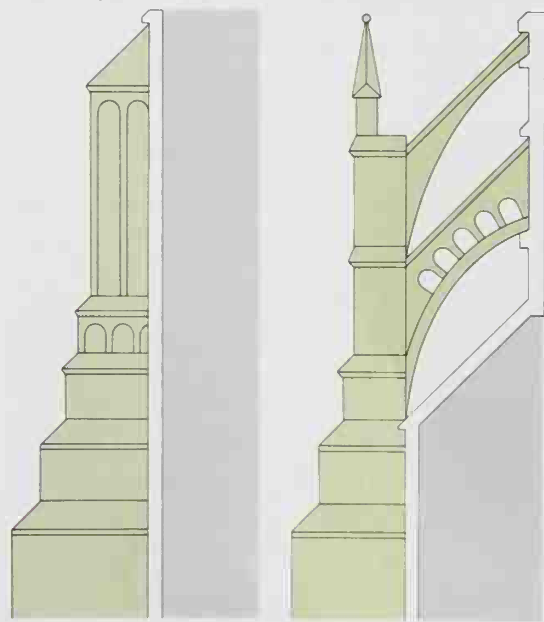
This article describes the basic elements of architecture and discusses the history of architecture throughout the world from its beginnings to the present. The article also surveys the education and training needed to become an architect as well as the various careers available in architecture.

Architectural terms



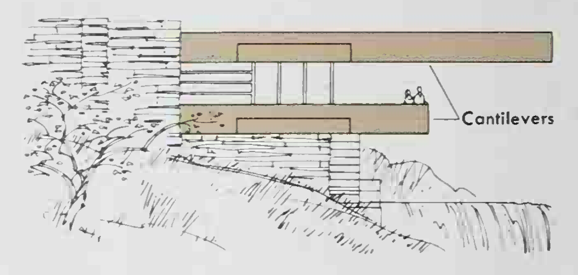
Ambulatory is a continuous aisle in a circular building. In a church, the ambulatory serves as a semicircular aisle that encloses the apse.

Apse is a semicircular area. In most churches, the apse is at the far end of the building and contains the main altar.

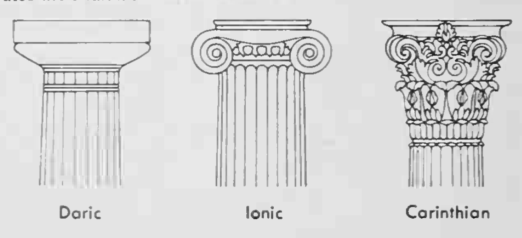


Arcade refers to a series of arches supported by columns or piers. A passageway formed by the arches is also called an arcade.

Arch is a curved structure used to support the weight of the material above it. The stone at the top of an arch is called the *keystone*.

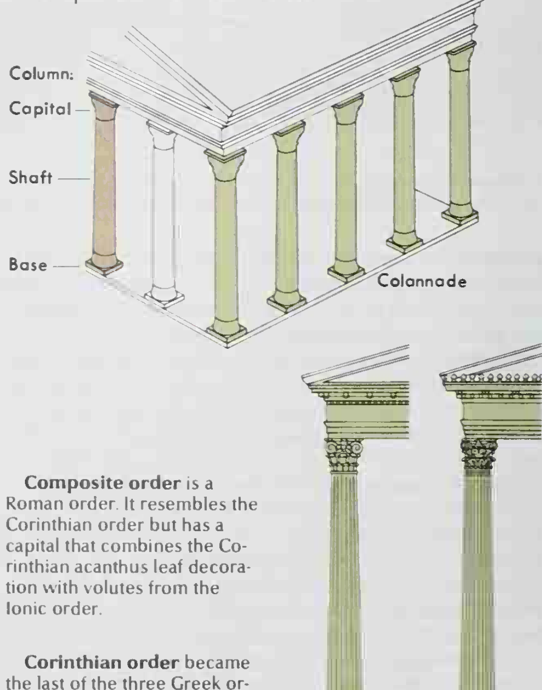


Architrave makes up the lowest part of an entablature. It rests on the capital of a column. For a drawing of an architrave, see Entablature on the opposite page.



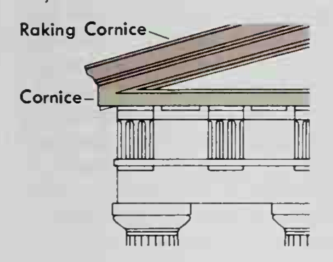
Buttress is a support built against an outside wall of a building. A *flying buttress* is an arched support that extends from a column or pier to the wall.

Cantilever is a horizontal projection, such as a balcony or a beam, which is supported only at one end.



Capital, in an order, forms the upper part of a column. It separates the shaft from the entablature.

Colonnade means a row of columns, usually set an equal distance from each other.



Column is a vertical support. In an order, it consists of a shaft and a capital and often rests on a base.

Composite order is a Roman order. It resembles the Corinthian order but has a capital that combines the Corinthian acanthus leaf decoration with volutes from the Ionic order.

Corinthian order became the last of the three Greek orders. It resembles the Ionic order but has an elaborate capital that is decorated with carvings of leaves of the acanthus plant.

Cornice forms the upper part of an entablature and extends beyond the frieze.

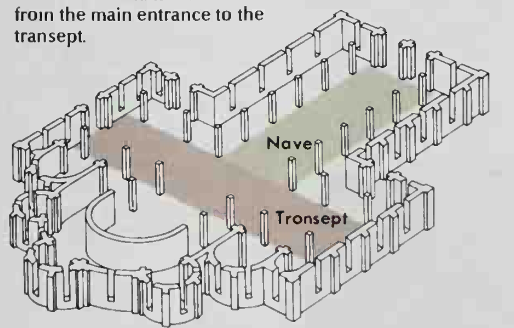
Doric order was the first and simplest of the three Greek orders. The Doric is the only order that normally has no base.

Doric Order

Entablature refers to the upper horizontal part of an order between a capital and the roof. It consists of three major parts– the architrave, frieze, and cornice.

Entablature:
Cornice
Frieze
Architrave

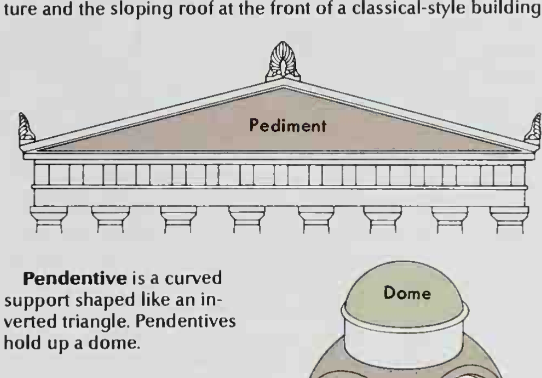
Facade is the front of a building. Most facades contain an entrance.



Frieze forms the middle part of an entablature and is often decorated with a horizontal band of relief sculpture.

Ionic order was the second of the three Greek orders. It has a capital decorated with carved spiral scrolls called *volutes*.

Module is a measurement, such as the diameter of a column, which architects use to establish the proportions of an entire structure.

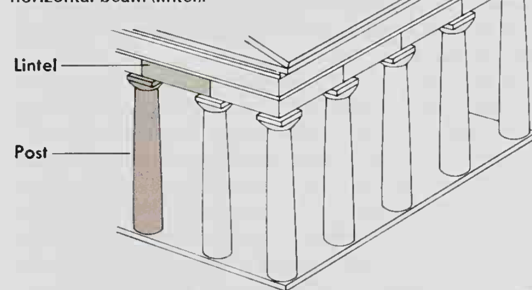


Ionic Order

Nave is the chief area within a church. It extends from the main entrance to the transept.

Order, in classical architecture, consisted of a type of column and entablature. Orders served as the basic elements of Greek and Roman architecture and influenced many later styles.

Pediment is a triangular area between the horizontal entablature and the sloping roof at the front of a classical-style building.

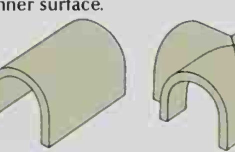


Pendentive is a curved support shaped like an inverted triangle. Pendentives hold up a dome.

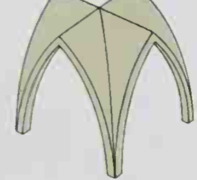
Dome
Pendentive

Pier refers to a supporting element other than a wall or column.

Post and lintel is a method of construction in which vertical beams (posts) support a horizontal beam (lintel).



Shaft is the main part of a column below the capital. Many shafts have shallow vertical grooves called *fluting*.



Transept forms the arms in a T- or cross-shaped church.

Tuscan order, a Roman order, resembles the Doric order, but the shaft has no fluting.

Vault is an arched ceiling commonly made of brick, concrete, or stone. A *barrel vault,* the simplest form of vault, is a single continuous arch. A *groined vault* is formed by joining two barrel vaults at right angles. A *ribbed vault* has diagonal arches that project from the inner surface.

Groined Vault
Ribbed Vault

In designing a building, architects think in terms of *space, planes,* and *openings.* They consider a building as space enclosed by planes—that is, by the surface of walls, floors, and ceilings. Openings include doorways, windows, and archways. An architect's basic task is to "shape" space into appropriate and practical forms through the arrangement of openings and planes. At various times in history, architects have considered certain shapes more beautiful than others and have emphasized them in their designs. The most popular shapes have included the square, rectangle, and sphere. Architects often combine two or more shapes in one design.

A building should be pleasing to look at, but it should also enable people to live or work in it comfortably and efficiently. In addition, the structure should be well built so that it can stand a long time without expensive maintenance. To create an attractive and efficient building, an architect must balance three major elements: (1) function, (2) appearance, and (3) durability.

Function. Every building is designed for certain purposes. A functional building—whether a small house or a gigantic office building—fulfills those purposes by serving the needs of its users in a pleasant and convenient way. The building is also designed to provide adequate heating, lighting, sources of power, and, in some cases, air conditioning.

Today, energy conservation has become an important consideration in architectural planning. For example, architects may use large windows or even entire walls made of glass to help heat a building with solar energy.

Many activities may take place within a building. In a house, common activities include eating, sleeping, bathing, and entertaining. Each activity has different requirements in regard to the location, size, lighting, and accessibility of the rooms in which the activity occurs. For example, a bedroom is a private room and should be set off from the rest of the living spaces. But everyone in a house uses the dining room, and so it should be more centrally located.

An office building involves a much more complex arrangement of space than a house. The architect must make sure that hundreds or perhaps thousands of workers can move quickly through the various parts of the building. In addition, visitors should be able to enter and leave the building easily. Parts of the structure may have to house special equipment, and a large amount of storage space may be required. The architect must also consider the activities that take place outside the building. For example, the building may require parking facilities. In addition, the architect may have to plan traffic patterns so that automobiles and other vehicles can approach and leave the building without crossing many lanes of traffic. Driveways must be wide enough for fire trucks to enter, and loading docks must be the proper height for delivery trucks.

Appearance. An architect determines the exterior appearance of the building not only by its shape but also by the choice of materials. The natural colors of stone, brick, and wood have always been popular, alone or in combinations. During the 1900's, tinted glass has played an important role in exterior building design. Many architects give special attention to texture in their designs. Some architects choose rough-textured wood or stone. Others prefer the sleek, elegant quality of highly polished glass and metal.

Many architects have created dramatic or pleasing patterns through the skillful arrangement of materials. For example, architects have used glass and concrete, various combinations of brickwork, or contrasting kinds of stone.

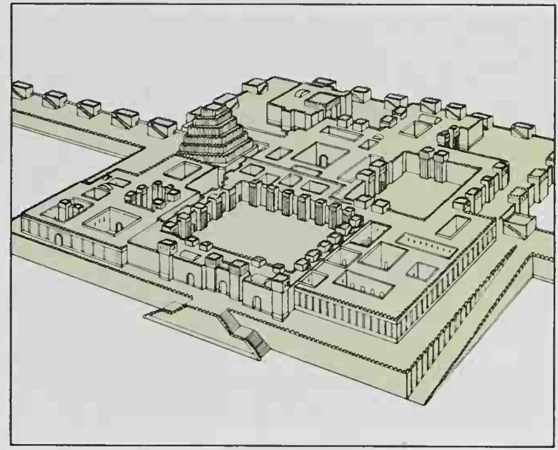
Proportion is vital to a building's appearance. All the parts of a building should be in proper relation to one another, neither too large nor too small. In addition, the size and shape of the building should blend with its site and surroundings. A tall glass-and-metal building would be appropriate in the downtown area of a large city, but it would be out of place in a neighborhood of single-family houses.

Durability. Most architecture is intended to stand a long time. To last many years without costly maintenance, a building must have a strong foundation. In addition, the exterior must be able to resist wear from the weather, and high-quality materials must be used in the interior.

Geodesic dome (1967), designed by Buckminster Fuller; Eric Hayes, Image Finders

A geodesic dome is a strong, lightweight dome that has no internal supports. Geodesic domes are made of standardized parts and so can be assembled and taken down quickly. The domes have been used for many purposes. The one at the left served as the United States pavilion at Expo 67, a world's fair held in 1967 in Montreal, Canada.

The first significant architecture appeared in two regions of the Middle East more than 5,000 years ago. One region was Mesopotamia, which lay between and around the Tigris and Euphrates rivers in what is now eastern Iraq, northeastern Syria, and southeastern Turkey. The other region was Egypt.

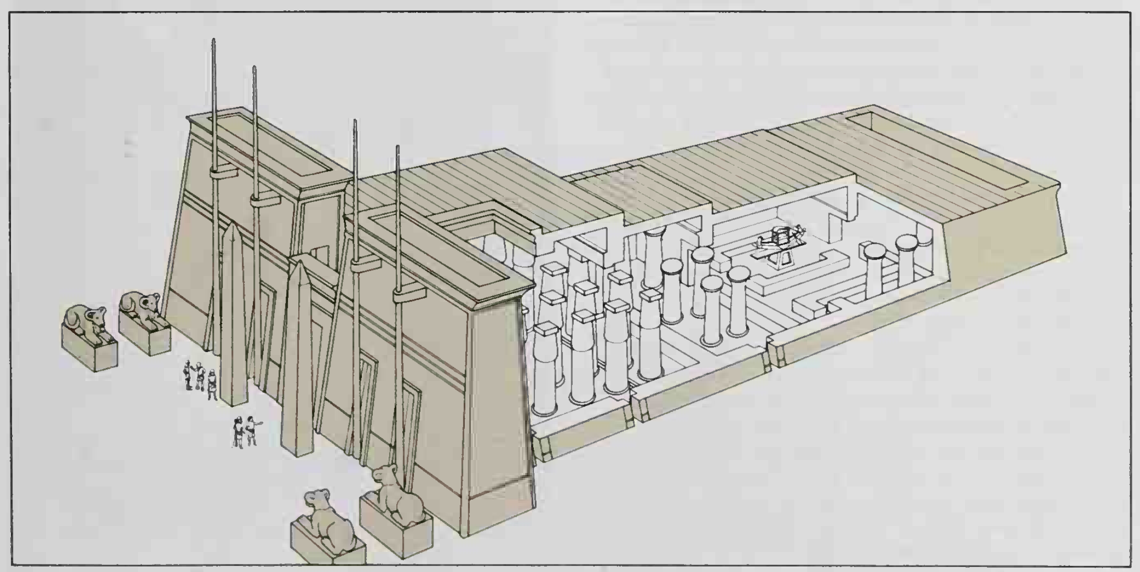


Mesopotamian architecture. Four major culture groups dominated Mesopotamian history. They were the Sumerians, Assyrians, Babylonians, and Persians. The history of the region was marked by numerous wars and invasions. Thus, the various cultures constructed many fortified buildings.

Most Mesopotamian buildings were made of brick and clay, which are not highly durable materials. As a result, no complete example of Mesopotamian architecture has survived. However, archaeologists have been able to reconstruct the plans of some buildings.

A Sumerian civilization developed in Mesopotamia sometime during the 3000's B.C. The first important Sumerian structures were temples. An early example was the White Temple (late 3000's B.C.) in the city of Uruk. The temple was made of whitewashed brick. Architects built the temple on a platform at the top of a pyramidlike tower. Such towers are called *ziggurats.*

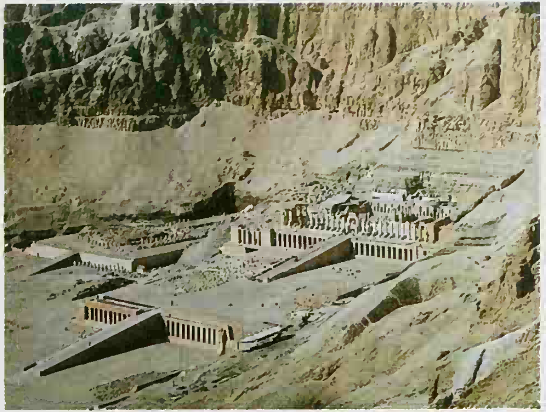
During the mid-700's B.C., the Assyrians conquered the region. They built palaces and temples influenced by Sumerian architecture but on a larger and more magnificent scale. The citadel of King Sargon II, which was built in the city of Khorsabad during the late 700's B.C., was one of the greatest achievements of Assyrian architecture. The citadel stood in the northwest corner of the city and included palaces, temples, public buildings, and a ziggurat. A fortified wall enclosed the city.



After the Assyrians fell in the 600's B.C., the Babylonians rose to power. They built a famous ziggurat referred to in the Bible as the Tower of Babel (early 500's B.C.). Their capital city of Babylon also included the famous Hanging Gardens and the Ishtar Gate, which was decorated with colored glazed brick. The gate is now preserved in the State Museums in Berlin, Germany.

WORLD BOOK illustration by Kevin Maddison

The citadel of King Sargon II was built in the Assyrian capital of Khorsabad during the late 700's B.C. The citadel included palaces, temples, public buildings, and a stepped pyramid called a *ziggurat,* which rose above the other structures.



In 539 B.C., the Persians conquered Mesopotamia. The Persian religion, Zoroastrianism, did not require temples. But the Persians built many palaces, most notably a palace complex in the religious capital of Persepolis. This group of adjoining buildings, which was completed in the mid-400's B.C., consisted of several palaces, halls, chambers, and courtyards. The Persian king re-

Queen Hatshepsut's temple was built about 1480 B.C. at Deir el-Bahri, Egypt. The Egyptians erected the temple at the foot of a huge cliff. Rows of columns supported a series of limestone terraces. A ramp provided access to each terrace.

ceived visitors in a huge room known as the Hall of One Hundred Columns. This room was 250 feet (76 meters) square with a vast beamed ceiling supported by columns perhaps 60 feet (18 meters) high.

For illustrations of Mesopotamian architecture, see **Babylon; Babylonia; Persia, Ancient.**

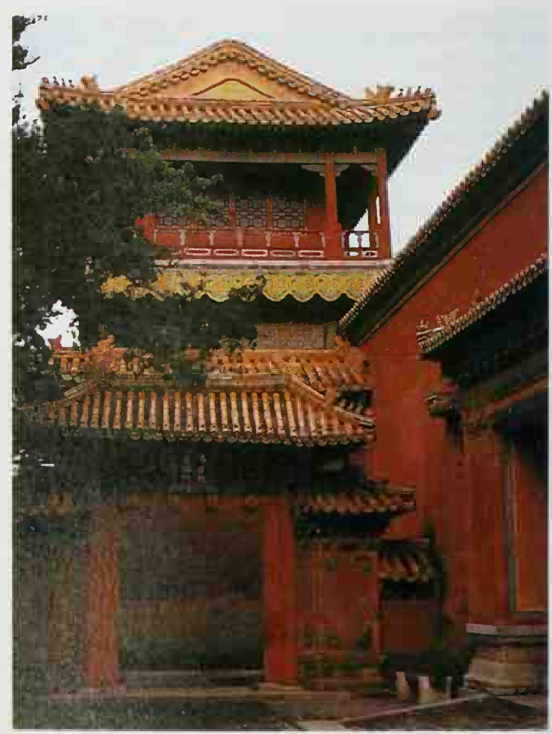
Egyptian architecture centered on the king, who was the religious as well as the political ruler of ancient Egypt. The Egyptians considered their kings to be gods, and they built stone tombs, temples, and palaces as monuments to them.

The best-known Egyptian tombs are huge pyramids in which the kings were buried. The ruins of 35 major pyramids still stand along the Nile River. Each pyramid was part of a group of structures that commonly included a large temple on the eastern side of the pyramid and a smaller temple near the Nile. A long passageway linked the two temples. The Egyptians probably considered the king's burial chamber the most sacred part of a pyramid. They blocked off and concealed the entrances to the pyramid and the chamber after the burial.

The first known Egyptian pyramid was built for King Zoser about 2650 B.C. at Saqqarah. It rises in a series of six giant steps. Three large and well-preserved pyramids were built from about 2600 to 2500 B.C. at Giza for Kings Khufu, Khafre, and Menkaure. These massive works originally had smooth sides.

A great period of Egyptian architecture began in the 1500's B.C. and lasted for about 500 years. Architects during this time mainly designed temples rather than pyramids. The temples were huge structures supported by columns. Ramps and halls connected the various rooms. People entered most temples through gateways formed by two huge towers called *pylons.* One unusual masterpiece of the period is the temple built for Queen Hatshepsut at Deir el-Bahri about 1480 B.C. Her subjects erected it along the foot of a huge cliff, vividly uniting architecture with nature.

For illustrations of Egyptian architecture, see Egypt, **Ancient; Pyramids.**



Asian and pre-Columbian architecture

Asian architecture has four main branches—Chinese, Japanese, Indian, and Islamic. Indian and Islamic architecture have had especially widespread influence. Indian architecture includes the architecture of Bangladesh, Burma, Cambodia, Indonesia, Nepal, Pakistan, Sri Lanka, Thailand, and Tibet as well as that of India. Islamic architecture refers to buildings designed by Muslims. Muslims are followers of Islam, the religion based on the life and teaching of the Prophet Muhammad. Islamic architecture can be found in the Middle East, northern Africa, Spain, and Asia.

Thousands of years ago, the ancestors of American Indians migrated from Asia to the Americas. By 100 B.C., several Indian groups, particularly in what is now Latin America, had developed brilliant cultures and produced magnificent architecture. American Indian art and architecture created before A.D. 1492 is called *pre-Columbian* because it was produced before Christopher Columbus arrived in the New World.

Chinese architecture. Chinese architecture began to develop in ancient times. The Chinese constructed a variety of buildings, but the chief structures were Buddhist temples and many-storied towers called *pagodas.*

Chinese temples consisted of rectangular wooden halls that featured an elaborate and beautiful arrangement of timber beams in the ceiling. Walls did not sup-

Section of the Forbidden City, begun in the A.D. 1400's, © Bruno Barbey, Magnum

Traditional Chinese architecture featured roofs that curved upward at the end. The roofs were supported by wooden columns connected to the ceiling beams by wooden brackets. The courtyard above is part of the famous Forbidden City in Beijing.

Guest House (A.D. 1629), Imperial Villa, Kyoto, Japan; Werner Forman Archive

Japanese architecture became noted for its simplicity, elegance, and sense of proportion. In a traditional house, *above,* thin walls are used to provide privacy rather than support. Partitions can be moved to change the room size.

port the roof but served simply as screens for privacy and for protection against the weather. The roof support came from posts connected to the ceiling beams by wooden brackets, many of which were carved, painted red, and coated with gold. The Chinese covered many of the roofs with blue, green, or yellow glazed tiles. The edges of the roofs curved gracefully upward.

For illustrations of Chinese architecture, see **Beijing; Korea; Pagoda.**

Japanese architecture has been strongly influenced by Chinese architecture. Thus, traditional Japanese architecture is based mainly on the use of wooden beams and posts. Shinto shrines, which are found throughout Japan, provide an excellent example. Shinto is the native religion of Japan. Shinto shrines are wooden frame structures built on posts that raise the shrine above the ground. Ceiling beams project beyond the walls and give the roofs a deep overhang.

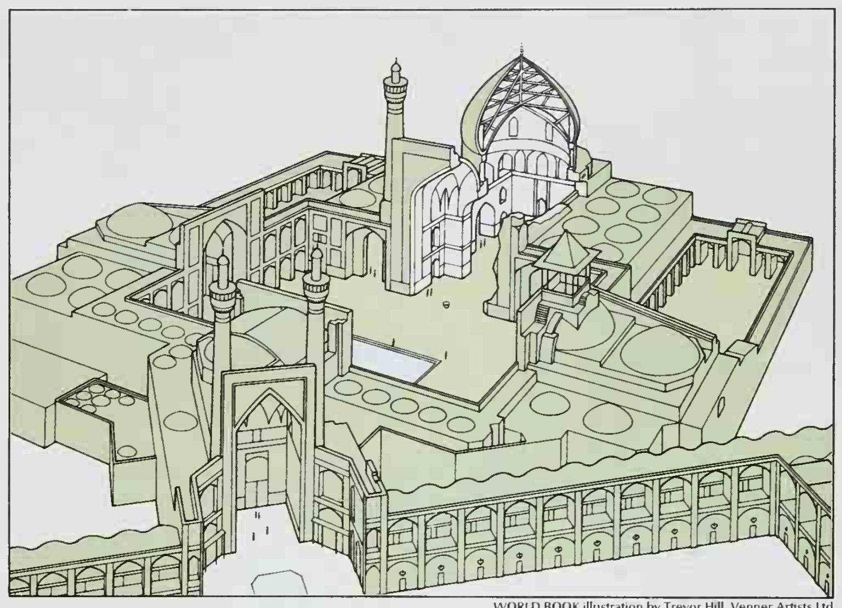
Traditional Japanese houses, whether large or small, have the same design. Upright posts support the roof. Sliding doors are built into the lightweight walls. The interior walls provide privacy rather than support. Many of the houses are set within walled gardens. For a picture of a traditional house, see **Japan** (Way of life).

Indian architecture had developed by the 200's B.C. The first great influence on Indian architecture was Buddhism, a major religion in India. Buddhism inspired the building of temples called *chaityas,* monasteries, and *stupas.* A stupa is a dome-shaped monument that houses relics of Buddha, who founded the religion in the 500's B.C. Many of the temples were carved from solid rock.

Hinduism and Islam also influenced Indian architecture. Hindu temples have rows of sculptured columns and richly carved exteriors, open porches, and spires. The Muslims conquered India during the 1500's and introduced their style of architecture. The outstanding Islamic building in India is the beautiful Taj Mahal (about 1630-1650) in Agra. Angkor (1100's), a group of temples in Cambodia, shows the Hindu influence on architecture outside India.

For illustrations of Indian architecture, see **India** (The arts); **Sculpture** (As part of architecture).

Islamic architecture. The most important Islamic building is the house of worship called a *mosque.* The styles of mosques vary among Islamic countries, but most mosques have a large courtyard surrounded by *colonnades* or *arcades.* A colonnade is a row of columns, and an arcade is a row of arches built on columns. The mosque walls are *faced* (covered) with colored brick, tiles, and stucco. Domes top many mosques. Mosques also have one or more towers known as *minarets.*



In addition to mosques, Muslim architects have designed palaces, tombs, and religious schools called *ma-*

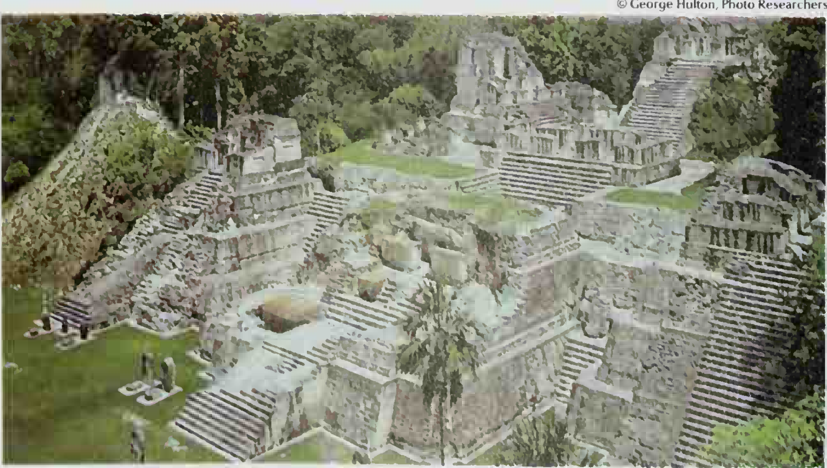
Angkor is a group of temples in Cambodia. The temples, built of richly carved sandstone, were begun in the A.D. 1100's and show the Hindu influence on architecture outside India. The main entrance, pictured at the left, is a long ceremonial gateway topped by three towers.

WORLD BOOK illustration by Trevor Hill, Venner Artists Ltd.

Islamic architecture has produced many beautiful houses of worship called *mosques.* The drawing at the left shows the Imperial Mosque in Isfahan, Iran. The domed sanctuary appears at the top. Four *iwans* (halls) with arched entrances surround the main courtyard. The slender towers are called *minarets.*

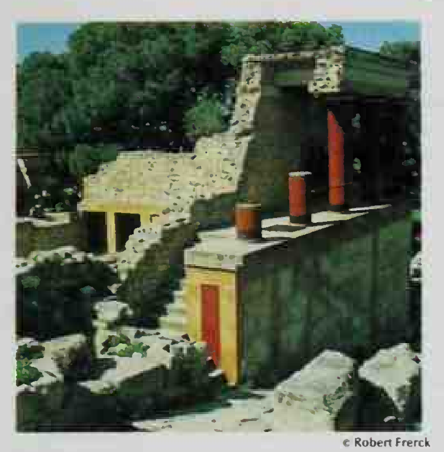
drasahs. The typical madrasah is a four-sided building surrounding a courtyard. In most cases, a large arched hall called an *iwan* is in the middle of each side of the building. Students hear lectures held in the iwans.

For illustrations of Islamic architecture, see **Islamic art; Jerusalem** (Islamic sites); **Spain** (The arts).



Pre-Columbian architecture. The Aztec, Toltec, Maya, and Inca developed the most important American Indian cultures in what is now Latin America. The Aztec and Toltec flourished in central Mexico. The Maya lived in Mexico and Central America, and the Inca built a huge empire in western South America.

Nearly all the surviving Aztec, Toltec, and Maya structures had a religious purpose. The most impressive of these structures were stone pyramids topped by small temples. The pyramids were part of ceremonial centers that also included altars, palaces, and plazas. The Inca built large temples, fortresses, and public buildings on mountainsides. Some of the best-known Inca ruins are at Machu Picchu, a site that lies in the Andes Mountains about 8,000 feet (2,400 meters) above sea level.



A number of Indian cultures developed in North America. The cliff dwellers of what is now the Southwestern United States created the most significant architecture. Their architecture consisted primarily of housing. The buildings rose next to cliffs like apartment houses. The Indians built their cliff dwellings of stone, adobe, or timber. Religious ceremonies were held in circular chambers called *kivas.* Most kivas were constructed underground.

For illustrations of pre-Columbian architecture, see **Aztec; City** (Ancient cities); **Colorado** (Visitor's guide); **Indian, American** (Indians of Middle America); **Maya;** Mexico (Arts); **Pyramids.**

Greek architecture can be traced back to palaces built on the island of Crete by a people known as the Minoans. Short wooden columns supported the Palace of Minos, *left,* built about 1500 B.C. in Knossos, Crete. By the mid-400's B.C., classical Greek architecture featured rows of beautifully proportioned stone columns in such structures as the Temple of Hephaestus, *right,* in Athens.

The term *classical architecture* refers to the building styles developed by the ancient Greeks and Romans. However, the roots of classical architecture can be traced to buildings created by two early Greek peoples—the Minoans and the Mycenaeans. Classical Greek architecture, in turn, greatly influenced Roman architecture.

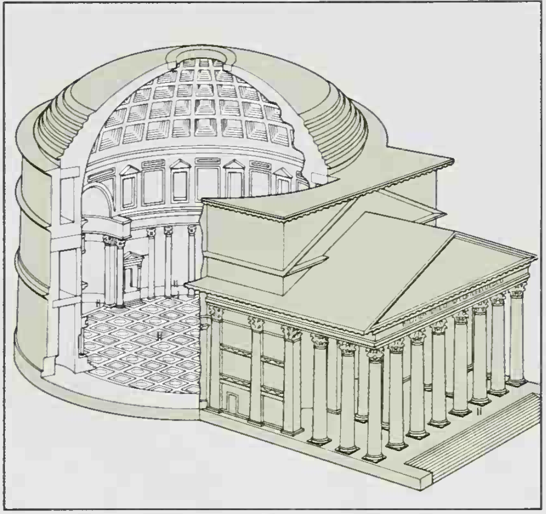
Minoan architecture. The Minoans developed the first important European civilization. The Minoans lived on the island of Crete in the Mediterranean Sea. The great age of Minoan architecture lasted from about 2000 to 1450 B.C.

The finest Minoan architectural achievement was the Palace of Minos (about 1500 B.C.) in the town of Knossos. This complex and sprawling structure had dozens of rooms built around a courtyard. Wooden columns supported the beams of the ceiling. Architects divided these beams into three horizontal sections. They were the *architrave* on the bottom, the *frieze* in the middle, and the *cornice* on top. The three sections together are called the *entablature.* The entablature became a vital part of later Greek architecture.

The Minoans also built palaces in the towns of Kato Zakro, Mallia, and Phaistos. All Minoan palaces served as administrative and commercial centers as well as royal residences.

Mycenaean architecture. The main center of the Mycenaeans was the city of Mycenae in southern Greece. After about 1600 B.C., they built beautifully cut stone tombs that resemble the shape of beehives. The finest example of a beehive tomb is called the Treasury of Atreus (about 1300-1250 B.C.).

The Mycenaeans constructed fortresslike palaces of huge stone blocks. The heart of the palace was a rectangular royal audience hall known as the *megaron.* A porch, which was supported by two columns, and a vestibule led to the megaron. The megaron had a hearth in the middle for an open fire. A hole in the ceiling allowed the smoke to escape. Four columns around the hearth supported the roof.



Classical Greek architecture has been imitated down to the present day. The best-known Greek contribution to architecture was a set of styles, called *orders,* of columns and their accompanying entablature. The Greeks used three basic orders—Doric, Ionic, and Corinthian. Each of the three orders had its own distinctive decoration.

The principal type of classical Greek building was the temple. Its design followed the plan of the Mycenaean megaron. A Greek temple generally included arrange-

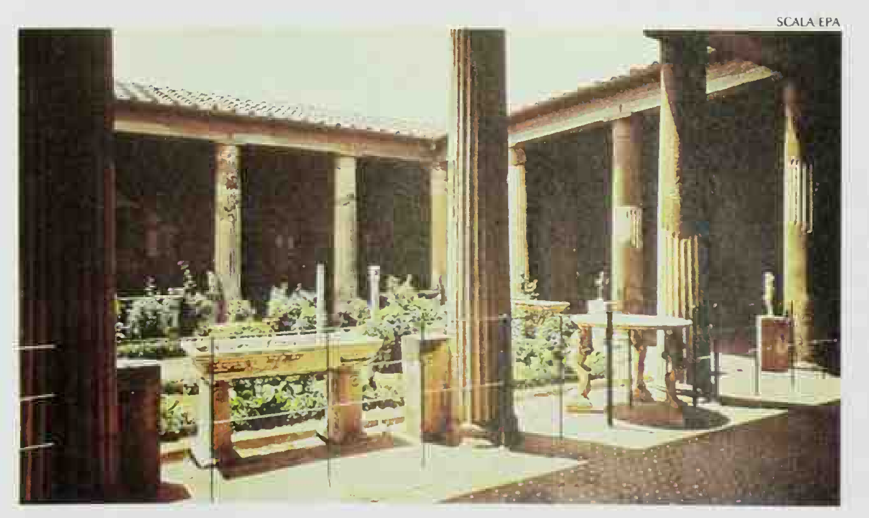
ments of columns that surrounded a long chamber for a statue of the god or goddess to whom the temple was dedicated. Many Greek temples were built on a hill that overlooked a city. Such a hill was known as an *acropolis.*

The Greeks developed formulas for the various styles of temples. The formulas set forth the order; the number, height, width, and spacing of the columns; and even the details of the smallest carvings. A typical formula was *Doric peripteral hexastyle. Doric* meant that the building would be erected in the Doric order with standard Doric ornamentation. *Peripteral* indicated that the building would be surrounded by a single row of columns. *Hexastyle* meant that the front entrance, or *portico,* would be six columns wide. Greek architects used the diameter of the column at its base as the unit of measurement for determining the proportions of the entire building. This unit is called the *module.*

In spite of the use of formulas, Greek temple designs had great flexibility and variety. A temple could be low and long or high and short. It might be simple or highly decorative. The number of columns could vary from 2 to more than 100.

For illustrations of Greek architecture, see **Athens; Column; Drama** (Greek drama); **Greece; Greece, Ancient.**



Roman architecture. The Romans ruled the largest empire of ancient times. At its peak, the Roman Empire included all the lands bordering the Mediterranean Sea. It also extended as far north as the British Isles and as far east as the Persian Gulf. Numerous architectural styles were used throughout the empire because many regions had developed their own building traditions. Nevertheless, Roman architecture had a great deal of stylistic unity. The Romans built more kinds of structures than did the people of any earlier civilization. In addition to houses, temples, and palaces, the Romans constructed such projects as aqueducts, public baths, shops, theaters, and gigantic outdoor arenas. Most of these structures were built during the period from about 100 B.C. to the A.D. 300's.

The Romans were the first to fully utilize two structural forms, the arch and the vault. A vault is an arched ceiling. The dome was a common form of vault in Roman architecture. The use of the arch and vault reduced or eliminated the need for columns to support the roof. Instead, the roof could rest solely on the outer walls. The Romans often used columns simply as sculptural decoration attached to walls.

A splendid example of Roman vault design are the Baths of Caracalla (A.D. 217) in Rome. The ruins of the building still stand. The baths had a system of vaults that covered vast areas of interior space. This space was so high and so deep that the Romans admired it as an extraordinary new form of architectural beauty.

For illustrations of Roman architecture, see **Rome; Rome, Ancient;** Forum, **Roman; Spain** (History); **Colosseum.**

SCALA EPA

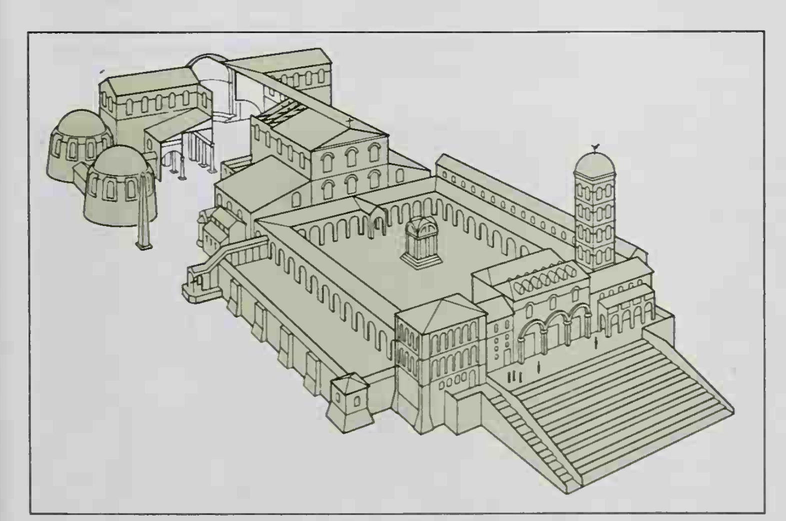
Country houses built by aristocrats in ancient Rome often featured a courtyard called a *peristyle.* A covered walkway enclosed the peristyle, which included a garden, fountains, and statues. The peristyle at the left was part of a residence called the House of the Vettii. It was excavated and restored at Pompeii, which was buried by the eruption of Mount Vesuvius in A.D. 79.

Medieval architecture refers to structures built in Europe during the Middle Ages. This historical period lasted from the A.D. 400's to the 1500's. The intellectual and spiritual life of medieval Europe centered on the Christian church, and so nearly all architects designed churches, monasteries, and other religious buildings. Castles, fortresses, and other nonreligious structures were also built.

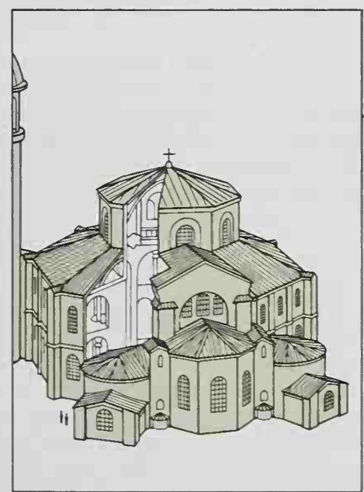
Medieval architects developed a number of styles. The *Byzantine* style became dominant in eastern Europe. In western Europe, the leading styles were the *Carolingian,* the *Romanesque,* and the *Gothic.* All four styles were preceded by early Christian architecture, which flourished from the 300's to the 500's.

Early Christian architecture. During the early centuries of Christianity, a number of regional cultures—and regional architectural styles—developed in Europe and the Middle East. But almost all early Christian architects borrowed heavily from the Romans. They based their chief type of church design, the *basilica,* on large Roman halls that were used for public meetings.

Old St. Peter's Church (begun about 330) was probably the first important early Christian basilica. It stood on the site of the present St. Peter's Basilica in Rome. Worshipers entered Old St. Peter's through a large open courtyard called the *atrium* and a vestibule called the *narthex.* The atrium and narthex separated the noisy city from the quiet church. The plan of the interior resembled the shape of a T. The long part of the T was the *nave.* Two aisles ran along each side of the nave. The *transept* formed the arms of the T. A semicircular space called the *apse* opened from the center of the transept at the far end of the church. The apse, which was covered by a half dome, contained the main altar.



In many basilicas, colonnades and arcades separated the interior into a nave and side aisles. The exteriors of most basilicas were plain brick or stone, but the interiors glowed with brilliant *mosaics* and *frescoes.* Mosaics consist of small pieces of glass, marble, or stone fitted together to form a picture or design. Frescoes are wall-paintings created on plaster.



Byzantine architecture. In 330, the Roman emperor Constantine the Great moved the capital of the empire from Rome to the city of Byzantium in what is now Turkey. Byzantium was renamed *Constantinople.* In 395, the Roman Empire split into two parts—the East Roman Empire, which had its capital in Constantinople, and the West Roman Empire, which had its capital in Rome. The West Roman Empire fell to Germanic tribes in the 400's. But the East Roman Empire thrived. It was called the *Byzantine Empire.*

By the 500's, a distinct Byzantine style of art had developed. The finest achievement of Byzantine architecture was the great domed cathedral Hagia Sophia (532-537) in Constantinople. It was designed by Anthemius of Tralles and Isidorus of Miletus. The Turks captured Constantinople in 1453 and later renamed the city *Istanbul.* They converted Hagia Sophia into a mosque. But the only change they made to the exterior of the building was to add four minarets.

Hagia Sophia has a huge central dome that tops a square space. This arrangement became a common feature of Byzantine architecture. Four curved and inverted triangles made of brick support the dome. These supports are called *pendentives.* By using pendentives, the architects could build a dome over a large square space. Inside Hagia Sophia, two-story arcades border the nave. Beautiful mosaics decorate the interior of the building. Mosaics were an important decoration in most Byzantine churches.

Other examples of Byzantine architecture include the Church of San Vitale (mid-500's) in Ravenna, Italy, the Basilica of St. Mark (begun in the mid-1000's) in Venice, Italy, and St. Basil's Cathedral (1555-1560) in Moscow. For

Early churches were built, in most cases, on the oblong *basilica* plan or the round or many-sided *centralized* plan. Old St. Peter's, *left,* which stood on the site of the present St. Peter's in Rome, was the best-known early Christian basilica. It was begun about 330. San Vitale, *right,* is a centralized church in the Byzantine style. It was built in Ravenna, Italy, in the mid-500's.

pictures of these churches, see Moscow; Venice. See also Byzantine art.

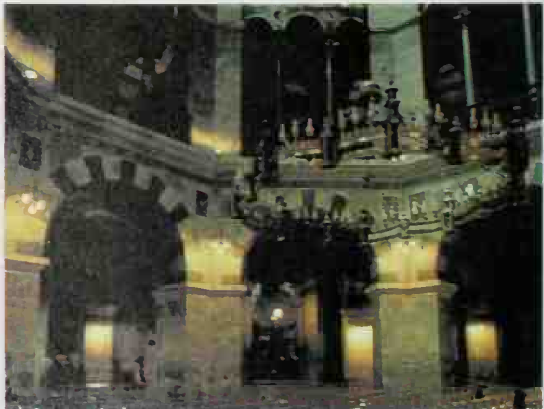
Carolingian architecture takes its name from Charlemagne, who was the king of the Franks from 768 to 814. From his capital at what is now Aachen, in western Germany, Charlemagne ruled a vast territory that included most of western Europe.

Charlemagne and his family wanted to revive the culture of early Christian Rome. Carolingian architects claimed that they copied early Christian architecture, but they changed the models to suit their needs. In particular, they made outstanding contributions to church and monastery design. The architects followed the plan of the basilica but added chapels, elaborate tombs, and high towers. They also invented an entrance known as a *westwork,* which included a porch, chapels, and small towers called *turrets.* Carolingian monks developed a monastery plan in which *cloisters* (covered walks) joined the church, library, kitchen, and other facilities.

Romanesque architecture began in the late 800's and achieved its greatest importance during the 1000's and 1100's. The most significant Romanesque buildings were churches designed in Italy, France, Germany, Spain, and England.

Scholars of the 1800's originated the term *Romanesque,* which means *like the Roman.* These scholars believed that Romanesque architecture chiefly reflected Roman designs. However, Romanesque architecture actually combined Roman with Byzantine styles and many new features.

Romanesque churches differed from country to country, but many of the churches shared certain features. The typical Romanesque church had thick walls, columns built close together, and heavy curved arches. A tower rose from the roof over the point where the transept crossed the nave. Four large supports called *piers* held up the tower. An arcade separated the nave from the side aisles. A gallery was built above the arcade. The *clerestory,* made up of a row of windows set in arches, topped the gallery.



During the Romanesque period, many people made *pilgrimages*—that is, journeys to sacred places. Groups of pilgrims traveled throughout Europe and Palestine to visit *pilgrimage churches,* which housed the bones or possessions of certain saints. Important pilgrimage churches were extremely large to accommodate the many visitors. An example is the huge Church of St. Sernin (about 1080-1120) in Toulouse, France. The church has two aisles on each side of the nave. Small chapels open into the *ambulatory,* a semicircular aisle enclosing the apse. This plan permitted pilgrims to move along the aisles without disturbing services at the main altar. See Romanesque architecture.

Gothic architecture flourished from the mid-1100's to as late as the 1600's in some parts of Europe. The word *Gothic* originated as a term of disapproval. It was used by artists and writers of the 1500's who wanted to revive the classical architecture of ancient Greece and Rome in Europe. They associated the Gothic style with the Goths, a Germanic people who had invaded Rome during the 400's. The artists and writers objected to the complicated Gothic designs, which differed so greatly

Romanesque architecture flourished in the 1000's and 1100's. Maria Laach Abbey Church in Germany, *above,* is dominated by a square tower and two turrets. The interior of Worms Cathedral, *right,* in Germany has rounded arches typical of the Romanesque style.

from the harmonious classical style.

A new system of construction enabled Gothic architects to design churches with thinner walls and lighter piers than was possible in Romanesque churches. Many piers consisted of clusters of columns several stories high. Gothic architects extended the piers into the roof area and then curved out the individual columns like the ribs of an open umbrella. The space between the ribs was filled in with masonry. These *ribbed vaults* were among the most distinctive characteristics of Gothic architecture. Other common features of the style included pointed arches and the substitution of stained-glass windows for large portions of the walls. Many churches also had *flying buttresses,* which were brick or stone arched supports built against the outside walls.

Sculptors carved the figures of saints and heroes of Christianity on church doorways. Medieval Christians believed that, in a symbolic sense, these saints and heroes inhabited and strengthened the church building.

For illustrations of Gothic churches, see **Cathedral; Chartres; Gothic art; Notre Dame, Cathedral of; Reims; Rouen; Strasbourg.**

Gothic cathedrals dominated French architecture from about 1150 to 1500. Arched supports called *flying buttresses* brace the exterior of the cathedral at Bourges, *above.* An arched ceiling called a *ribbed vault* covers the nave of the cathedral at Amiens, *right.*

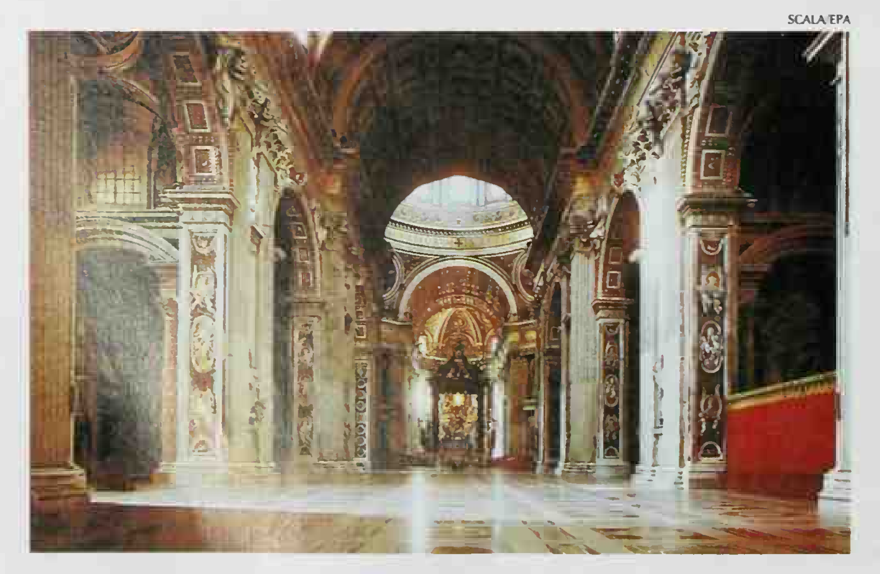
Renaissance architecture

Raymond V. Schoder

The dome of the Cathedral of Florence was an early achievement of Italian Renaissance architecture. Filippo Brunelleschi designed the dome, which was completed in 1436, partly on the principles of Roman vaults.

SCALA/EPA

The Church of Sant' Andrea in Mantua, Italy, was designed by Leon Battista Alberti in the mid-1400's. The front resembles a Roman temple with an arch.



The word *renaissance* means *rebirth.* In European history, it refers to the great rebirth of interest in classical culture, especially that of ancient Rome.

Renaissance architecture started in Italy in the early 1400's and spread throughout Europe during the 1500's. A group of Italian scholars, some of whom were amateur architects, influenced Renaissance architecture. These scholars knew classical culture well and considered it superior to the culture of their time. Architects studied Roman ruins and tried to model their designs on classical buildings. They adopted the classical orders as well as Roman and Byzantine vaults, especially domes.

Early Renaissance architecture began during the early 1400's. The originator of the new Renaissance style was Filippo Brunelleschi of Florence. Brunelleschi's first great project was the dome (1420-1436) for the Cathedral of Florence. The cathedral was begun in 1296 in the Gothic style of the late Middle Ages. Brunelleschi followed this style in designing the octagonal dome, but he also used a vault technique inspired by the Romans. Italians considered the Brunelleschi dome to be the greatest engineering accomplishment of their time.

Brunelleschi also designed other notable structures in Florence. They include the Foundling Hospital (begun in 1421), the Church of San Lorenzo (begun in 1421), and the Church of Santo Spirito (begun in 1436). The two churches were not completed until the second half of the 1400's, after Brunelleschi's death. In all of these buildings, the architect revived the classical forms that became basic elements of the Italian Renaissance style. For example, he used Corinthian columns in the Church

SCALA/EPA

St. Peter's Basilica stands in Rome on the site of Old St. Peter's. Construction began in 1506 and took about 150 years. Ten architects worked on the project. The view at the left looks down the nave toward the main altar, which was designed by Gian Lorenzo Bernini, one of the church's most important architects.

SEF/EPA

The Villa Rotonda, designed by Andrea Palladio in the mid-1500's, stands on a hill near Vicenza, Italy. A porch based on classical Roman temple designs extends from each of the building's four sides. A low dome covers the circular central hall.

of San Lorenzo. The church has a geometric balance and harmony typical of Renaissance architecture.

Leon Battista Alberti was another leading Italian Renaissance architect. Alberti also wrote an influential book about classical architecture titled *On Architecture* (begun in the 1440's). The book stimulated scholars to discuss architectural theory for its own sake apart from its application in actual buildings.

Alberti completed only a few designs, but they had great impact on later architects. He designed the *facade* (front) of the Church of Santa Maria Novella (about 1456-1470) in Florence. He decorated the facade with black and white marble, arranging a pattern of circles, squares, and rectangles in the upper stories. These patterns were taken from classical decorations and gave an impression of mathematical proportion and harmony. Alberti also designed the Church of Sant' Andrea (begun in 1470) in Mantua. The church's exterior has none of the sculptured Christian figures and other features typical of Gothic architecture. Alberti designed the facade to resemble a classical temple with a large arch in the center.

Later Renaissance architecture. The greatest building project of the later Renaissance was the reconstruction of St. Peter's Basilica in Rome. The project began in 1506, when Pope Julius II decided to demolish Old St. Peter's Church and build a new church on the site. The rebuilding was completed in the late 1600's. Altogether, 10 Italian architects worked on the church during that time. The project's leading architects included Donato Bramante, Michelangelo, and Gian Lorenzo Bernini.

Bramante was the original architect of St. Peter's. He designed the structure as a combination of square, circular, and *Greek cross* forms. A Greek cross has four arms of equal length. Michelangelo designed the great ribbed dome (completed in 1591, after his death) as a Renaissance version of Brunelleschi's Gothic-style dome on the Cathedral of Florence.

Another great Italian Renaissance architect was Andrea Palladio. During the middle and late 1500's, Palladio designed Roman-inspired villas and palaces, which he published in a book that made him one of the most influential architects in history. His Villa Rotonda (begun about 1567) near Vicenza particularly influenced English and American architects of the 1700's.

From Italy, Renaissance architecture spread to France in the early 1500's and then to other European countries. At first, architects in these countries followed Italian models. However, they rapidly developed distinct national styles.

The finest French Renaissance buildings are magnificent *châteaux* (castles), such as those built at Fontainebleau, Chambord, and Azay-le-Rideau mainly during the early 1500's. In Spain, Juan de Herrera designed much of the Escorial (1563-1584) near Madrid. This enormous building consists of a church, a monastery, a palace, and

a college. Inigo Jones produced the most notable early examples of Renaissance architecture in England during the early 1600's. He based his superb Banqueting House (1622) in London on Palladio's designs.

For illustrations of Renaissance architecture, see **Bramante, Donato; Jones, Inigo; Vatican City.**

Baroque architecture

Baroque architecture began in Rome during the early 1600's. It soon spread throughout Italy and to other parts of Europe. Baroque architects sought to produce highly dramatic effects in their works. The typical baroque building featured curved forms, an extravagant and intricate use of columns, and ornate sculptures and paintings for decoration.

The leading supporters of baroque architecture were the Roman Catholic Church and powerful European monarchs. Church support resulted from the Counter Reformation of the 1500's and 1600's. This movement of renewal within the church stimulated a great outpouring of religious enthusiasm in Catholic countries. Architects designed elaborate baroque churches and monasteries that reflected the drama and emotion of this religious spirit. At the same time, strong monarchs wanted architecture that would glorify their reigns. Magnificent baroque palaces expressed the authority of these rulers.

The most spectacular examples of the baroque style appeared in Italy, Austria, Spain, and southern Germany. Gian Lorenzo Bernini, Francesco Borromini, and Guarino Guarini rank as the outstanding baroque architects in Italy. The baroque fascination with columns is reflected in the keyhole-shaped colonnade (begun 1657) that Bernini designed to enclose the courtyard of St. Peter's Basilica. Borromini's curves and twisted shapes characterize the famous Church of Sant' Agnese in Piazza Navona (1666) in Rome. The Church of San Lorenzo (1668-1687), located in Turin, is one of Guarini's finest designs.

Johann Bernhard Fischer von Erlach of Austria and Balthasar Neumann of Germany designed many fine baroque churches and palaces in their countries. The extremely elaborate Spanish baroque style is often called *Churrigueresque.* The name comes from three brothers—Alberto, Joaquín, and José Churriguera—who were early leaders of the style.

In France and England, the baroque style was far less extreme than it was in other European countries. French and English architects retained the Renaissance square, rectangle, and circle as basic forms of decoration. They designed enormous buildings with simple lines and row after row of columns or windows.

Perhaps the greatest French baroque building is the magnificent Palace of Versailles (begun about 1661). Its major architects were Louis Le Vau and Jules Hardouin-Mansart. The palace is more than $\frac{1}{4}$ mile (0.4 kilometer) long and has about 1,300 rooms.

Sir John Vanbrugh designed the most extravagant English baroque palace, Blenheim Palace (1705-1724) in Oxfordshire. However, the leading English architect of the baroque style was Sir Christopher Wren. His design for St. Paul's Cathedral (1675-1710) in London is a masterpiece of the style.

For pictures of St. Paul's Cathedral, see **London.** For other pictures of baroque architecture, see **Versailles, Palace of; Wren, Sir Christopher.**

Michael Holford

St. Paul's Cathedral in London is a masterpiece of English baroque architecture. Sir Christopher Wren designed the church in the late 1600's. He included columns and other elements of classical Greek and Roman architecture.

Michael Holford

Rococo architecture was highly decorative. The refined, ornamental character of the rococo style can be seen at the left in the Hall of Mirrors in the Amalienburg Pavilion, in southern Germany, near Munich. The Flemish-born architect François Cuvilliés designed the graceful building in the 1730's.

During the 1700's, three major architectural styles appeared in Europe: (1) rococo architecture, (2) the Palladian Revival, and (3) neoclassical architecture. In addition, colonial architecture in America began to flourish in the 1700's. Colonial architecture was heavily influenced by European styles.

Rococo architecture was the final phase of the baroque style. It developed in France about 1720 and spread to other countries during the next 60 years. Compared with the monumental baroque style, rococo architecture was light and delicate. However, rococo buildings had even more elaborate decorations than did baroque structures. In France, the outstanding rococo buildings were elegant houses built in Paris for the nobility. But the most impressive rococo structures were palaces, churches, and monasteries erected in southern Germany and Austria. Dominikus Zimmermann created a rococo masterpiece in his design for Die Wies pilgrimage church (1754) in southern Germany. For a picture of the church, see **Germany** (Arts).

The Palladian Revival mainly reflected the classical designs of the Renaissance architect Andrea Palladio. The style began in the early 1700's and was most important in England, though it also appeared in northern Italy and North America. Most Palladian Revival buildings were country houses.

Colen Campbell, a Scottish architect, introduced the Palladian Revival style. However, the leader of the movement was Lord Burlington, an English amateur architect. Burlington and his friend William Kent designed the first great Palladian Revival building, Chiswick House (1726) in London. Burlington and Kent modeled their design on Palladio's Villa Rotonda. The architects set the house in a large garden based on what they believed a Roman garden looked like. Such gardens became a common feature of Palladian Revival architecture.

Neoclassical architecture reflected a renewed interest in the architecture of ancient Greece and Rome. The prefix *neo* means *new.* Neoclassical architecture was inspired by buildings discovered in the ancient Roman cities of Pompeii and Herculaneum. The cities had been buried by an eruption of Mount Vesuvius in A.D. 79. Archaeologists began excavating the cities in the mid-1700's.

Neoclassical architects followed Greek and Roman styles more closely than Renaissance architects had done. Like baroque architects, the neoclassicists designed colonnades and large structures, especially public buildings. But in their designs, they used simpler geometric forms, such as the square and sphere, rather than the baroque swirls and curves.

The most important neoclassical architects in England were Sir William Chambers and Robert Adam. Chambers designed many public buildings, notably Somer-

The Palladian Revival was based on Roman architecture and the works of Andrea Palladio. Chiswick House, *above,* in London was the first important English Palladian Revival building. Lord Burlington and William Kent designed it in the mid-1720's.

His Grace the Duke of Northumberland

Neoclassical architecture followed Greek and Roman designs. Robert Adam used Ionic columns and classical-style sculpture in Syon House (1769), *above,* built in London.

set House (1780) in London. Adam became an influential interior designer and furniture designer as well as a leading architect. He made Roman designs fashionable in such country houses as Osterley Park House (1763-1780) in London.

Pietro Bianchi, an Italian architect, designed one of the major neoclassical buildings of the early 1800's, the Church of San Francesco di Paola (begun about 1816) in Naples. The design of the church is based on that of the Pantheon, an ancient Roman temple. However, the curved exterior colonnade shows the influence of Bernini's colonnade for St. Peter's Basilica.

French architects designed many neoclassical buildings. One of the most famous is the Panthéon (about 1757-1790) in Paris. Jacques Soufflot designed it. The Panthéon was originally a church named after Sainte Geneviève, but the building is now a public monument.

In the United States, neoclassical architecture became known as the *Federal* style. The leading Federal style architects were Benjamin Latrobe and Charles Bulfinch. Latrobe is best known for his designs for the United States Capitol in Washington, D.C. Bulfinch's most important projects included the statehouses of Maine and Massachusetts.

For illustrations of neoclassical architecture, see **Adams, John; Furniture** (English styles); **Maine; Washington, D.C.;** (Government).

Colonial architecture in America developed mainly from European styles of the Middle Ages and the Renaissance. In Latin America, the baroque and Spanish Renaissance styles dominated in the Spanish and Portuguese colonies. In the Spanish colonies in what is now the Southwestern United States, missionaries built adobe churches that combined American Indian and Spanish architectural styles. In time, however, the colonists adapted European influences to suit regional tastes and needs.

In the Northern Colonies, the colonists built wooden houses designed to withstand the cold winters. Most of the houses were small, with one or two rooms that could be heated easily. The houses had sloping roofs to shed snow. Architecture in the Middle Colonies showed the influence of a number of European styles. In New York, for example, many Dutch colonists followed architectural styles in the Netherlands and built houses of brick with wooden shutters. In the Southern Colonies, wealthy planters constructed the largest colonial residences, modeling some of these buildings on English country houses. Thomas Jefferson designed several buildings in Virginia that reflected neoclassicism and the Palladian Revival.

For pictures of colonial architecture, see the *Visitor's guide* section in the articles **Arizona; New Mexico; Virginia.** See also **Colonial life in America; Jefferson, Thomas; Williamsburg.**

Topsfield Historical Society, Mass.

Mike Mazzaschi, Stock, Boston

Early American architecture reflected European styles. The timber frame design of the Parson Capen House, *above,* shows the influence of medieval English architecture. Colonial settlers in Topsfield, Mass., built the house in 1683. The State House in Boston, *right,* resembles an English neoclassical building. It was designed by Charles Bulfinch and completed in 1798.

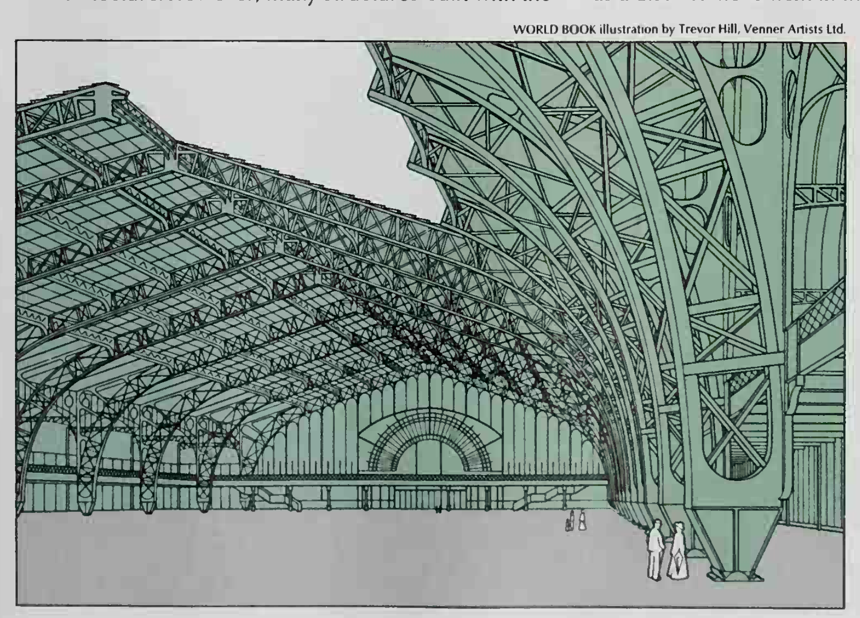
By the early 1800's the development of architecture was greatly affected by the rapid growth of industrialization in western Europe and eastern North America. This *Industrial Revolution* created a demand for architects to plan new types of buildings and to devise new construction techniques. At the same time, many architects revived various styles of the past. The most important revivals were the *Greek Revival* and the *Gothic Revival*. A number of architects combined two or more earlier styles into one design.

The Industrial Revolution began in Britain during the 1700's and spread to other European countries and to North America by the early 1800's. For centuries, architects had concentrated on designing religious buildings, castles and palaces, and country houses. The Industrial Revolution required such structures as factories, railroad stations, warehouses, and office buildings. Architects used new materials and new methods to design the new structures.

The Industrial Revolution led to the first commercial and industrial world's fair, the Great Exhibition of 1851 in London. The fair was housed in the Crystal Palace (1851), a revolutionary glass and iron structure designed by Sir Joseph Paxton. The building covered almost 19 acres (8 hectares) and looked much like a giant greenhouse. Paxton's Crystal Palace was also the first important *prefabricated* structure. The iron frame and glass panels were manufactured in a factory and then assembled at the site of the exhibition.

The success of the Great Exhibition brought about similar fairs in other cities in Europe and in the United States. These exhibitions required special facilities and gave architects an opportunity to test new ideas. The Crystal Palace and later glass and iron exhibition halls influenced the development of the glass and metal skyscrapers of the 1900's.

The Crystal Palace did not resemble any earlier style of architecture. However, many structures built with the new technology preserved associations with historical styles. For example, the English architects John Dobson and Philip Hardwick designed a number of railroad stations with neoclassical facades. Hardwick also used cast-iron Doric columns to support his St. Katherine's Dock warehouses (1828) in London. The French architect Henri Labrouste combined new building techniques with the Renaissance style in the library of Sainte Geneviève (1850) in Paris. The library has walls of traditional masonry, but the vaults and columns are made of iron. Labrouste allowed the iron to show, making the library the first major public building to use iron as part of the architectural style.



The Greek Revival began in the late 1700's. It ended as a distinct movement in the mid-1800's, though build-

The Gothic Revival of the 1800's reflected a renewed interest in medieval Gothic architecture. In the 1860's, William Butterfield designed these buildings at Oxford University in Oxford, England, in the revival style. Butterfield's use of stone and colored brick shows his interpretation of the Gothic architectural style.

ings in the Greek style are still being built. The Greek Revival style was considered especially appropriate for such buildings as museums, stock exchanges, banks, and government offices. Advances in classical scholarship enabled architects to re-create Greek designs with great accuracy.

A leading Greek Revival architect in England was Sir Robert Smirke. He designed the British Museum (1823-1847) in London to resemble a huge Greek temple of the Ionic order. William Strickland designed the first important Greek Revival building in the United States, the Second Bank of the United States (1824) in Philadelphia. The front of the structure resembles a Greek temple of the Doric order.

Erich Lessing, Magnum

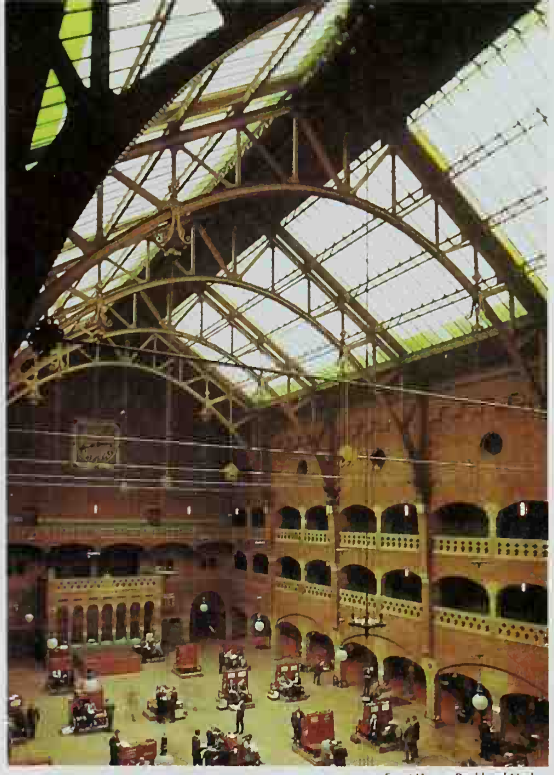
The Palais Garnier features a number of architectural styles. The Grand Staircase, *pictured here*, shows strong baroque influences. Charles Garnier designed the building in 1861.

The Gothic Revival. The Gothic style never went completely out of fashion. In the centuries after the Middle Ages, various architects used elements of the Gothic style. But the revival of Gothic as a deliberate architectural movement began in the 1700's and reached its peak during the mid-1800's. The movement declined by the 1880's.

During the early and mid-1800's, the English architect A. W. N. Pugin wrote several influential books supporting the Gothic style. Pugin urged architects especially to design churches in the Gothic style because it best expressed the Christian faith. The most ambitious project of the Gothic Revival was the Houses of Parliament (1840-1860) in London, designed by Pugin and Sir Charles Barry. William Butterfield, another English architect, created a number of highly individual designs in the Gothic style. One of his best-known Gothic buildings is All Saints' Church, Margaret Street (1849-1859) in London. Among Butterfield's most important projects was his design for Keble College (1860's) at Oxford University in Oxford, England. Butterfield designed the entire college, including the library, chapel, and residence halls, in the Gothic Revival style.

For a picture of the Gothic Revival, see **Parliament**.

Combined styles. Some architects of the 1800's combined what they considered to be the best features of two or more historical styles. The former home of the Paris Opera, the Palais Garnier (1861-1875), is a masterpiece of this approach, called the *eclectic* approach. The building's designer, Charles Garnier, planned the huge structure chiefly in the elaborate baroque style. For example, the spectacular Grand Staircase features a lavish use of colored marble. However, Garnier also included classical orders and elements from the designs of French and Italian Renaissance palaces.

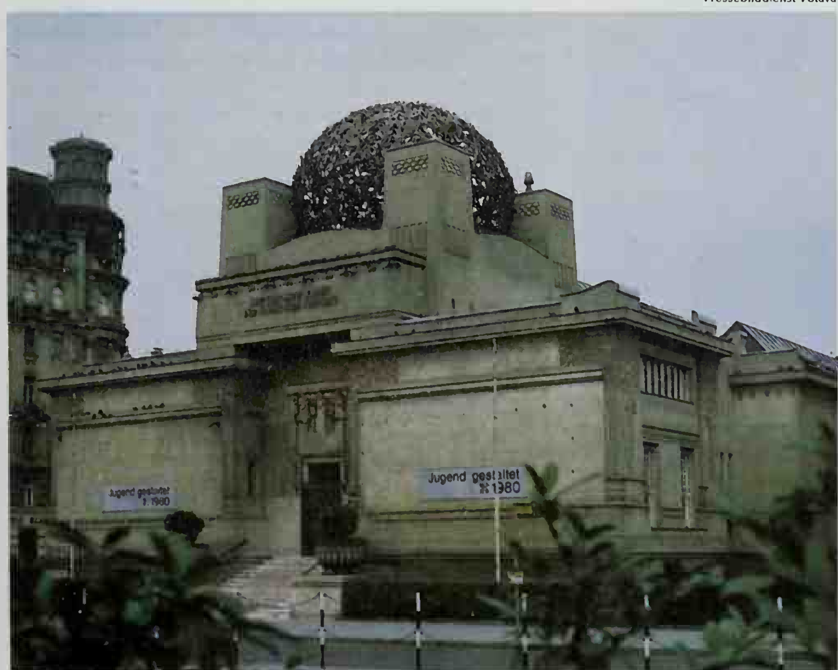


The period from the late 1800's to the present has been one of the most creative and productive times in the history of architecture. Architects have used new materials and new building methods to develop the first completely new styles in centuries.

During the modern era, American architects made an international impact on architecture for the first time. For example, the skyscraper, perhaps the best-known symbol of modern architecture, was first developed in the United States.

The remarkable changes in architecture since the late 1800's have emerged from the theories and works of a few individuals and small groups. Many masterpieces of modern architecture were designed or influenced by four men—Frank Lloyd Wright of the United States; Walter Gropius and Ludwig Mies van der Rohe of Germany; and Charles Jeanneret-Gris, generally known as Le Corbusier, of France.

Early modern architecture in Europe. Modern architecture in Europe originated as a reaction against the historical revivals and combined styles of the 1800's. Young architects tried to find fresh approaches that would reflect their time.



One of the first important influences on modern architecture was the Arts and Crafts Movement, founded in the mid-1800's by William Morris in England. Morris had studied to be an architect, but he gave up the profession to concentrate on interior design. Morris criticized the poor artistic quality that he saw in the machine-made products of the Industrial Revolution. With other artists in the Arts and Crafts Movement, Morris created original and high-quality designs for furniture, stained glass, textiles, and wallpaper. Although Morris did not design buildings, his influence encour-

Ernst Heyer, Burkhard-Verlag

The Amsterdam Stock Exchange in Amsterdam, the Netherlands, is noted for its simple lines and an extensive use of brick. Hendrik Petrus Berlage designed the building in 1896.

Pressebilddienst Votava

The Secession Building in Vienna, Austria, was designed in 1898 by Josef Olbrich as an exhibition gallery for a group of artists and architects called the Vienna Secession. The building's simple, cubelike form and flat, undecorated walls became common characteristics of modern architecture.

Ernst Heyer, Burkhard-Verlag

The Palais Stoclet, a mansion completed in 1911 in Brussels, Belgium, was designed by Josef Hoffmann of Austria. It features a geometric shape, plain white walls, and a dramatic tower.

aged a new artistic freedom and spirit of experimentation that played an important part in modern European architecture.

Most of the first modern architects worked in the Netherlands, Austria, and Germany. In the Netherlands, Hendrik Petrus Berlage used an unusual red brick design for his masterpiece, the Amsterdam Stock Exchange (1903). The building's simple, spare design marked a departure from the highly decorative revival structures and pointed toward more modern styles.

Otto Wagner founded modern architecture in Austria during the 1890's. Wagner was a teacher and theorist as well as an architect. His most important designs were houses with horizontal lines and little ornamentation. The structures had flat, slablike roofs that projected beyond the walls. These features characterized much architecture of the 1900's.

Josef Olbrich and Josef Hoffmann, two of Wagner's students, joined with other Austrian artists and architects to found a group known as the Vienna Secession. The group was united by its rebellion against the revival styles. Olbrich designed the Secession Building (1898), an exhibition gallery in Vienna for the group. He took the Renaissance and neoclassical style of the domed villa and redesigned it in modern terms. Wagner's influence appears in the building's projecting slab roof and undecorated walls. Hoffmann designed a house called the Palais Stoclet (1911) in Brussels, Belgium. The

Steiner House in Vienna has a cubelike shape and no decoration. Adolf Loos, who designed the building in 1910, fiercely opposed any ornamentation in architecture

Ernst Heyer, Burkhard-Verlag

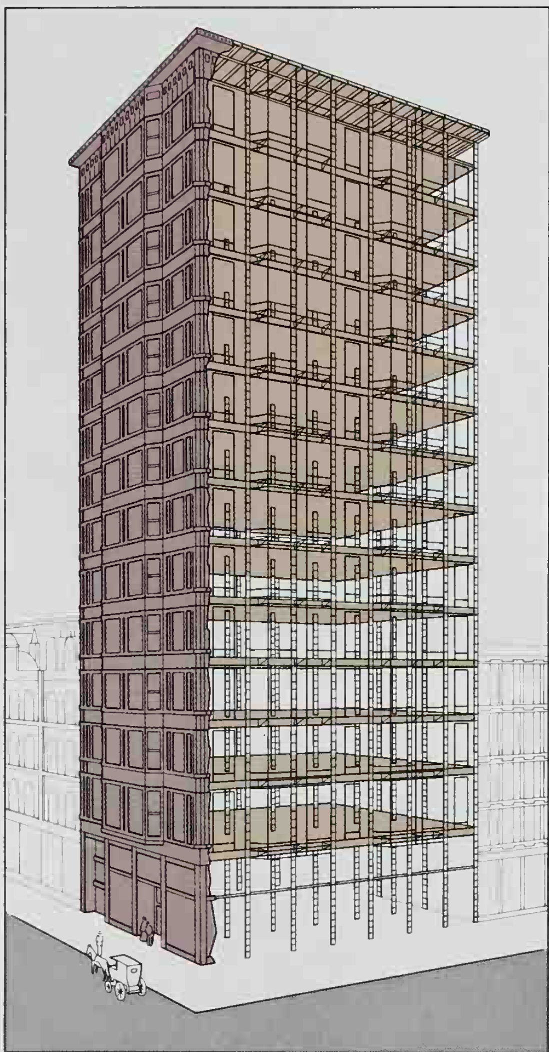
The AEG Turbine Factory, with simple lines and glass walls, was one of the first factories to reflect modern design principles. It was designed in 1909 in Berlin by Peter Behrens.

plain white walls and cubelike geometric outlines of the house made it one of the most advanced architectural works of the early 1900's.

Adolf Loos, another Austrian, fiercely opposed decoration in architecture. He believed that the decorative qualities of a building would emerge naturally from the structure's materials and form. Loos designed Steiner House (1910) in Vienna and other buildings with cubelike shapes and no ornamentation.

In Germany, Peter Behrens designed some of the first factories to reflect modern architectural ideas. His most significant design was the AEG Turbine Factory (1909), a glass, steel, and concrete building in Berlin. Behrens also influenced the theories of Mies van der Rohe, Gropius, and Le Corbusier, all of whom worked in his office during the early 1900's.

Early modern architecture in America. Henry Hobson Richardson became the first important architect in the United States to include modern elements in his designs. Richardson was a leading American architect from about 1870 to his death in 1886. He worked in a variety of medieval styles, especially Romanesque. However, he often used features of modern design in the simplified geometric forms and absence of exterior ornamentation in his later works. Richardson designed a number of buildings with both Romanesque and modern elements, including the Glessner House (1887) and the Marshall Field Wholesale Store (1887), both in Chicago.



Chicago became the center of modern architecture in the United States during the late 1800's and early 1900's. The Great Chicago Fire destroyed much of the city in 1871, giving architects an opportunity to test new ideas as the city was rebuilt.

William Le Baron Jenney designed the 10-story Home Insurance Building (1885) in downtown Chicago. The building is often considered the world's first metal-framed skyscraper. Instead of thick walls, a steel frame supported the building. The walls provided no support but hung like curtains on the frame. The steel frame and *curtain wall* became basic to modern design.

Jenney trained a number of architects in his Chicago office. They included Louis Sullivan and Daniel Burnham. Sullivan became the leader of a style of architecture called the *Chicago School.* Other Chicago School architects included Burnham, Dankmar Adler, and John Wellborn Root. These architects gained fame for their steel-frame stores and office buildings. Sullivan designed the Carson Pirie Scott & Company Building (1906), a Chicago department store that is famous for its horizontal bands of windows and skillful use of light-colored brick. Sullivan also designed skyscraper office buildings, such as the Wainwright Building (1891) in St. Louis and the Guaranty Building (1895) in Buffalo, N.Y.

Burnham became even better known as a city planner than as an architect. However, he designed several significant commercial buildings. His Railway Exchange Building (1904) in Chicago is noted especially for its many windows.

For pictures of early modern architecture in America, see **Burnham, Daniel Hudson; Richardson, Henry Hobson; Sullivan, Louis Henri.**

WORLD BOOK illustration by Trevor Hill, Venner Artists Ltd

The Reliance Building in Chicago was one of the first modern skyscrapers. The firm of Daniel Burnham and Company designed the building, which was completed in 1894. This cutaway drawing shows the building's steel-frame construction.

Frank Lloyd Wright was the greatest figure in modern American architecture. Wright worked in Chicago for the firm of Adler and Sullivan from 1887 to 1893, when he began his own practice. Wright gained international attention for a series of houses he designed from about 1900 to 1910 in the *prairie style.* The houses had low, horizontal shapes because Wright believed that such a design blended with the open Midwestern prairies. He said that a building should "grow" from its site. Wright selected materials in earth colors and emphasized the natural appearance of those materials.

Wright revolutionized the arrangement of interior space in his prairie houses. In traditional American houses of the late 1800's, walls divided the interior into boxlike rooms. In his houses, however, Wright reduced

the number of walls so that one room flowed into another. This flexible use of interior space and the horizontal outlines of the houses greatly influenced European architects. Wright's best-known prairie house is Robie House (1910) in Chicago. Wright also designed large projects, such as the Larkin Building (1906) in Buffalo, N.Y., and Unity Temple (1908) in Oak Park, Ill. His bold and imaginative use of concrete in these buildings helped popularize the use of the material in modern architecture.

Wright's most impressive later project was perhaps the buildings he designed for the Johnson Wax Company in Racine, Wis. The main administration building (1939) has a smooth exterior of brick and glass. Inside the building, the chief office area is a large windowless room lined with balconies. Soft light enters the area through strips of glass tubing located at the edges of the ceiling. Thin concrete columns rise from the floor of the building and support large concrete disks at the ceiling level.

For other pictures of Wright's work, see **Wright, Frank Lloyd; Furniture** (The 1900's); **United States** (The arts).

Walter Gropius influenced modern architecture both as an architect and as a teacher. In 1919, he founded the Bauhaus, a school of design in Weimar, Germany. The school was dedicated to uniting the arts and architecture with modern industrial technology. In 1925, the Bauhaus moved to Dessau. Gropius designed the buildings for the Dessau campus. The geometric concrete and glass structures rank among the finest designs of the period.

Gropius came to the United States in 1937. The next year, he became chairman of the Department of Architecture at Harvard University. Gropius' architectural theories spread throughout the United States as a result of his work as an architect and teacher. In 1946, Gropius and some of his former students along with other young architects formed the Architects Collaborative. The group designed many projects in the United States and other countries, beginning with the Graduate Center (1950) at Harvard.

The International Style dominated architecture until about 1950. The name came from the title of a book, *The International Style* (1932). The book was written by two Americans—Philip Johnson, an architect, and Henry-Russell Hitchcock, an architectural historian. In the book, the authors reviewed architecture of the previous 10 years and stated that a new and distinct "international" style had developed in many countries.

The International Style actually summarized many of the ideas of such pioneer modern architects as Hoff-

Hedrich-Blessing

The Carson Pirie Scott & Company Building, a Chicago department store, is a masterpiece of the Chicago School of architecture. The Chicago School was a pioneering group of modern American architects based in Chicago. The store was designed by Louis Sullivan and completed in 1906. It features horizontal bands of windows separated by light-colored stone. Sullivan decorated the first two stories with ornamental black cast iron.

Hedrich-Blessing

The prairie style created by Frank Lloyd Wright revolutionized American domestic architecture. The houses he designed in the prairie style emphasized horizontal lines and natural materials that harmonized with the landscape. Wright designed the prairie house above in 1902 in Oak Park, Ill.

mann, Loos, Wright, and Gropius. Typical buildings in the style have geometric shapes, white walls, and a flat roof with a garden. Most are constructed of *reinforced concrete.* Such concrete has embedded metal rods for added strength. Typical International Style buildings also have large windows to create a light, airy feeling. The exteriors, of buildings in this style have little or no ornamentation.

Le Corbusier was probably the greatest architect to work in the International Style. Most of his early works were houses that resembled white boxes. The houses were built of white reinforced concrete and stood above the ground on pillars called *pilotis.* One of Le Corbusier's most important houses in this style was the Villa Savoye (1931) in Poissy, France (see picture on following page).

Le Corbusier's later works showed more variety than his cubelike houses. One of his most famous later projects is the Unité d'Habitation (1952), a 337-unit apartment building in Marseille, France. As in his earlier works, Le Corbusier had this building constructed of reinforced concrete and raised on pilotis. But he honeycombed the exterior with balconies to shield the apartments from the strong sun. The balconies created a lively pattern of dark and light rectangles in the sunlight. Le Corbusier had the walls at the sides of the balconies painted in bright colors to provide vivid contrasts with the white concrete.

Ludwig Mies van der Rohe was the master of glass and steel architecture. He designed skyscrapers that had a steel frame and thin metal and glass walls. The style became popular for commercial buildings after World War II (1939-1945).

Mies, as he was generally called, became director of the Bauhaus in 1930 and served in that position until the school closed in 1933. In 1937, he immigrated to the United States. The next year, he became head of the architecture department at the Armour Institute (now the Illinois Institute of Technology) in Chicago. In 1939,

The Bauhaus was a German art school that greatly influenced modern architecture. Walter Gropius designed the Dessau campus in 1925, including the building above.

The International Style became one of the dominant architectural movements of the 1900's. Le Corbusier, the leader of the movement, designed the Villa Savoye, *left,* in Poissy, France. The residence, completed in 1931, includes the major elements of the International Style. The structure has a geometric shape, white concrete walls, a flat roof, and a continuous band of windows. It stands on pillars called *pilotis.*

Gerard Mathieu, A.F.I.P.

Mies began to design the buildings for a new Armour Institute campus. His designs stressed rectangular, cubelike structures of brick, exposed steel columns, and huge windows.

Mies designed several apartment and office building skyscrapers in the United States. His Lake Shore Drive apartment complex (1951) in Chicago resembles two gigantic glass rectangles. Perhaps his most praised project is the Seagram Building (1958), an office skyscraper in New York City. Mies designed it with Philip Johnson. The building has walls of bronze and bronze-tinted glass.

Architecture today. The International Style remained the most popular style for major architectural projects throughout the world until about 1950. By that time, younger architects were reacting against it. These architects believed that the style lacked variety in design because of the emphasis on simple geometric shapes and the lack of decoration.

The attack against the International Style was first led by a group of architects often called the *brutalists.* The brutalists based their designs on the later work of Le Corbusier. They created plain, massive buildings with rough reinforced concrete exteriors. Leading members

Artstreet

The works of Ludwig Mies van der Rohe are noted for his skillful use of steel and glass. In 1939, Mies began designing the campus for what became the Illinois Institute of Technology in Chicago. The large areas of tinted glass in Crown Hall (1956), *above,* are typical of his style.

of this movement included Kenzo Tange of Japan, the partnership of James Stirling and James Gowan of England, and Paul Rudolph of the United States. Like the brutalists, the American architect Louis Kahn made imaginative use of concrete. Kahn's major designs include the Salk Institute for Biological Studies (1965) in La Jolla, California, and the Kimbell Art Museum (1972) in Fort Worth, Texas.

Perhaps the best-known architectural movement of the late 1900's was *Postmodernism,* which began during the 1960's. The Postmodernists had no style or theories in common. They were united only in their rejection of the International Style. One of the leading Postmodern theorists and designers was Robert Venturi. Other American architects generally grouped as Postmodernists included Peter Eisenman, Frank Gehry, Michael Graves, Charles Moore, and Stanley Tigerman.

Many Postmodernists revived historical styles that had been ignored by earlier modern architects. For example, Venturi often used traditional styles, borrowing from the Italian Renaissance and other periods. Venturi became one of the first Postmodern architects to add ornamentation to building exteriors. A number of Postmodernists incorporated arches, columns, domes, and other classical elements into their designs.

In 1978, Philip Johnson, the coauthor of *The International Style,* unveiled the design he created with John Burgee for the first Postmodern skyscraper. This building, the American Telephone and Telegraph Company (now AT&T Corp.) headquarters in New York City, has a base resembling the Pazzi Chapel of the Renaissance.

This interest in historical styles was accompanied by concern for preserving old buildings and adapting them to new uses. Many government agencies were created to preserve buildings of architectural value. These agencies have the power to grant *landmark status* to such buildings. Buildings with landmark status may not be destroyed or significantly altered.

© David Falconer, West Stock

Postmodernism used elements from earlier architectural styles. Michael Graves featured color and sculpture in his Portland Building, completed in Portland, Oregon, in 1982.

In the late 1900's and early 2000's, such architects as Frank Gehry of the United States and John Outram of the United Kingdom explored the possibilities of tilting walls, other antigeometric forms, and brilliant color. Gehry's most famous building was the Guggenheim Museum (1997) in Bilbao, Spain. Outram's major designs included the Judge Institute of Management Studies (1995) at Cambridge University in England and the Anne and Charles Duncan Hall (1997) at Rice University in Houston.

Tom Brown

The British Art Center at Yale University was the last major work by Louis Kahn, a leading American architect of the mid-1900's. The center, which opened in 1977, shows Kahn's creative use of concrete walls, simple geometric shapes, and natural light.

Careers

Young people who want to become architects face a long and difficult training period. The following discussion deals with the training and licensing of architects in the United States.

Education and training. High school students interested in becoming architects should take courses in art, history, foreign languages, mechanical drawing, social studies, and especially mathematics. Students are also encouraged to take courses in computer science if such courses are available. In addition, students able to obtain a part-time job in an architect's office can gain valuable experience.

After graduating from high school, future architects must attend college. There are about 90 accredited schools of architecture in the United States. In addition, several hundred colleges and trade schools offer some technical courses in architecture. However, a person can become a licensed architect faster by attending an accredited school.

Accredited schools offer a five-year program that leads to an undergraduate professional degree. Students with a bachelor's degree in architecture may take one or two years of additional courses to receive a master's degree or do still further advanced work to earn a doctorate. Most architectural schools stress practical design and the *case method,* in which the class solves architectural problems related to an actual building.

College graduates must pass a design test, which is given annually in June. Then they must work as an *intern* in the office of a licensed architect or in the office of an engineer or contractor. However, an internship in an architect's office can be completed in a shorter time.

Upon completing the internship, architects take a licensing examination supervised by a state board. The examination, called the Architect Registration Exam, is given in June of each year. It consists of nine divisions that cover design, construction, materials, and safety.

The United States has about 65,000 licensed architects. Only a small number of them are women, but the number of women architects has risen rapidly.

Information about architectural schools can be obtained from the American Institute of Architects (AIA) in Washington, D.C. The institute also publishes literature on architecture, holds meetings, and awards prizes for excellence in architectural design.

Employment opportunities. Licensed architects may open their own office or join an architectural firm. Various city, state, and federal agencies also employ architects. The great majority of architects work for a firm. Most young architects specialize in a certain phase of the profession, such as designing houses, schools, or office buildings.

People with training in architecture can also work in related fields. These fields include city planning, furniture design, industrial design, and interior design. There also is an increasing demand for architects who can recondition existing buildings of artistic or historical value, and for specialists in laws governing architectural preservation. G. L. Hersey

Archon, *AHR kahn,* was the title of certain high-ranking administrators in many of the city-states of ancient Greece. Archons handled various executive and judicial duties. In Athens, three archons originally were chosen from prominent families to serve life terms. Beginning in 682 B.C., the people of Athens elected nine archons from the population at large to serve one-year terms. Archons were chosen by lot after 487 B.C.

The Arctic landscape changes dramatically with the seasons. Winter snow piles up around a hut built by Inuit (sometimes called Eskimos), and provides a bed for sled dogs, *left.* In summer, flowers blanket the tundra region, *right.* Most of the Arctic has no snow during July and August.

Arctic, *AHRK tihk* or *AHR tihk,* is the region of continuous cold around the North Pole. It includes the Arctic Ocean, thousands of islands, and the northern parts of the continents of Europe, Asia, and North America. People long believed that the Arctic was a cold, barren place where human beings could not live. But explorers and scientists found that, except for Greenland, nine-tenths of all arctic lands have no snow and ice in summer. Berries, vegetables, and flowers grow in a few places. The sun never shines on much of the Arctic during the winter months. However, it shines on the entire region for at least part of the day from March to September.

The Arctic has great importance to human beings. Information from arctic weather stations helps scientists predict the weather farther south—in Europe, Asia, Canada, and the United States. The airplanes that fly over the Arctic daily from Europe to such Pacific Coast cities as Los Angeles and Seattle are doing what people had dreamed of doing for hundreds of years. They are following a short route between Europe and the Pacific Ocean.

Northern nations such as Canada and the United States have built military installations in the Arctic to protect their frontiers and trade routes. To build these military installations, people have had to learn many things about this harsh region of the world. Engineers have learned how to construct houses on the permanently frozen soil, and scientists have studied the plant and animal life to find ways that people can survive in the Arctic.

Arctic lands

Scientists define the boundaries of the Arctic in different ways. To an astronomer, the Arctic Circle forms the limits of the region (see **Arctic Circle; Arctic Ocean** [color map]). Other scientists consider the Arctic as the region surrounded by a line drawn through all northern locations with an average summer temperature of 50 °F (10 °C). This line is known as *the 50° summer isotherm* (see **Isotherm**). It closely follows the *tree line,* the line north of which forests do not grow. Many animals and birds that live in the forests cannot survive in the Arctic. As a result, the 50° summer isotherm and the tree line mark an important geographic boundary. Generally speaking, the Arctic includes the northern parts of Alaska, Canada, Norway, Sweden, Finland, and Russia. The Arctic also includes all of Greenland and most of Iceland.

The true Arctic. The 50° summer isotherm passes south of the southern tip of Greenland. In Canada, it runs from Happy Valley-Goose Bay, Labrador, through Churchill on Hudson Bay, to Liverpool Bay in the Beaufort Sea. The isotherm parallels the southern edge of the Brooks Range in Alaska. It then swings south along the Bering Sea to the Aleutian Islands. The line turns northward again from the tip of the Aleutians to the Gulf of Anadyr in Siberia, where it turns to follow the Arctic Circle. In the western part of Russia, it swerves northward, barely touching the northern coast of Norway. Then the line turns southward and runs south of all but the southern coast of Iceland.

The subarctic. South of the true Arctic lies a region that is almost as cold in winter, but which has much warmer summers. This region is commonly called the subarctic. It consists of all areas north of a line where the average temperature is not higher than 50 °F (10 °C) for more than four months of the year. Subarctic areas include parts of central Asia and Siberia, central Alaska and Canada, and parts of northern Europe. Most geo-

graphers consider the subarctic a part of the Arctic in terms of economic and military importance.

Natural resources

The Arctic has served as an important source of food since prehistoric times. Over 10,000 years ago, during the last period of the Ice Age in Europe, people who made tools like those of the modern Inuit (sometimes called Eskimos) hunted in the Arctic. Today, the world's best fishing grounds lie along the Arctic's edge, particularly off the coasts of Greenland and Iceland. Rich mineral deposits have also drawn people to the region.

Soil forms slowly in the Arctic. The severe cold and heavy snow slow the action of forces that break rock into soil in temperate climates (see **Soil** [How soil is formed]). Almost anywhere that a person digs in the Arctic or subarctic, the shovel soon hits a layer of soil that is permanently frozen. This soil, called *permafrost,* consists mostly of gravel in some places. In others, it may be composed of finer materials. The permafrost sometimes reaches depths of 5,000 feet (1,500 meters). The warmth of spring thaws the soil near the surface, but the deeper layers remain frozen.

Minerals. Valuable deposits of coal are found in Alaska, Canada and its northern islands, Greenland, and Siberia. There are also coal mines in Svalbard, a group of Norwegian islands in the Arctic Ocean. Subarctic areas of Canada have deposits of radioactive minerals, including thorium and uranium. Iron, lead, nickel, and petroleum occur in widespread parts of northern Canada and Russia. Petroleum also comes from Alaska. Northern Norway, Sweden, and Finland have iron deposits. Mines in Alaska, Canada, and Russia produce gold and copper. Tin mines operate in northern Russia. The only known large natural deposits of cryolite (used to make aluminum and glass) lie in Greenland.

Plant life. Swampy plains with low shrubs, mosses, and *lichens* (simple, plantlike organisms) cover most lands north of the tree line. These areas are called the *tundra* (see Tundra). Other common arctic plants include grasses, sedges, and flowers such as saxifrages. Sphagnum moss and related plants thrive in ponds, and sometimes form muskeg. Willows and similar trees grow in some areas, but none grows larger than shrubs. Nearly 1,700 kinds of plants grow in the Arctic and subarctic. These include about 900 varieties of flowers. Poppies, bluebells, and other flowering plants bloom even in northern Greenland during the summer.

Dark evergreen forests thrive south of the tree line. They consist mainly of cedars, firs, pines, and spruces, mingled with birches. These subarctic forests are called *taiga* (*TY guh*). A transitional zone lies between the taiga and the tundra. In this zone, the trees are sparse and seldom grow over 40 feet (12 meters) tall. Dwarf willows, birches, and alders mix with evergreens, and reindeer moss sometimes forms a thick carpet.

The Arctic

Scientists define the boundaries of the Arctic in several ways. The *tree line* is the northern limit of tree growth. It separates the Arctic from the northern forests. The climatic boundary of the Arctic lies on the *summer isotherm* (50 °F or 10 °C). These lines are shown on the map at the right.

WORLD BOOK map

Animal life. The most common animals in the Arctic and subarctic are reindeer and caribou. Vast herds roam the arctic pastures. Trappers prize ermine, martens, and sables for their furs. Other animals that provide food and furs include bears, foxes, hares, and squirrels.

Lemmings and voles compete with the caribou and reindeer for the arctic grass. A single pair of these mouselike creatures may have more than a hundred descendants a year. Their number reaches a high point every three or four years. This cycle in the lemming and vole population affects other animals and people. Snowy owls and other birds, together with foxes, eat the creatures. The birds fly north in great numbers when there are many lemmings and voles to eat. The foxes raise large families because of the abundant food supplies. Then the Inuit can trap more foxes and sell their furs. However, the lemmings and voles deplete the grasses as their numbers increase. This forces the caribou to move away. Without large herds of Caribou, the Inuit have less food and fewer skins with which to make their traditional clothing. The whole cycle begins again as the grasses grow once again, and the lemmings and voles increase.

Most arctic birds live on or near the water, where they find their food. The most common arctic bird is the old squaw duck. Eider ducks and willow ptarmigans also may be found almost everywhere in the Arctic. Other birds that nest in the region include falcons, geese, loons, ravens, sandpipers, and snowbirds. Auks, petrels, puffins, and terns live on the coastal lowlands and islands. Gulls, dovekies, murres, and sea pigeons nest on the arctic cliffs. For a discussion of marine mammals and fishes in the Arctic, see **Arctic Ocean**.

Climate. Winter temperatures average about −30° F (−34° C) throughout most of the true Arctic, including the area around the North Pole. The coldest weather occurs in northeastern Siberia, in the region around Verkhoyansk. There, January temperatures average −40° F (−40° C), and have reached −93° F (−69° C), which is probably colder than it has ever been at the pole. Most other parts of Siberia and the subarctic sections of central Asia, Canada, and central Alaska have average winter temperatures of about −20 °F (−29° C). The mildest winters occur in coastal regions of the Atlantic and Pacific oceans, where January temperatures average about 30° F (−1° C). These same regions have mild summers, with average July temperatures of around 45° F (7° C). The warmest summers occur in the inland regions of Siberia, Alaska, and Canada. July temperatures there average around 60° F (16° C). Weather stations have recorded temperatures of 90° F (32° C) and higher in these regions.

Winter storms in the Arctic develop chiefly in two areas where the barometric pressure remains low. One of these areas, called *the Aleutian low,* extends from eastern Siberia to the Gulf of Alaska. The other, *the Icelandic low,* covers central Canada, half of the Arctic Ocean, and parts of the North Atlantic Ocean and northern Europe. Storms that begin in these areas tend to travel from northwest to southeast. Weather stations in Alaska can warn of storms approaching Canada and the continental United States. Reports from Greenland and Iceland help forecasters predict storms in Europe.

Rainfall in many arctic regions totals 6 to 10 inches (15 to 25 centimeters) a year, including melted snow. This is less rain than falls on some of the world's great deserts. Much of the Arctic has rain and fog in summer. In spite of the low annual rainfall, arctic lands may be very wet underfoot because the moisture evaporates slowly and drainage conditions are poor.

Arctic peoples

A number of peoples live in the Arctic. They come from a variety of backgrounds, but all have adapted to the Arctic in similar ways. For example, all arctic peoples make their clothing from animal skins. Their chief food is meat and fish. People along the arctic coasts depend mostly on fishing and on seal and whale hunting for a

Some people of the Arctic

Many Arctic peoples use modern conveniences. An Inuit (Eskimo) girl of Greenland wears a zippered jacket instead of a traditional hand-sewn parka. A Yakut man of Siberia lives in a modern home where he makes carvings of an ancient style. A Sami couple use a snowmobile, rather than reindeer, to pull their sleigh. Most Inuit also use snowmobiles, but some have dog sleds.

livelihood. Those living inland hunt wild caribou or herd reindeer.

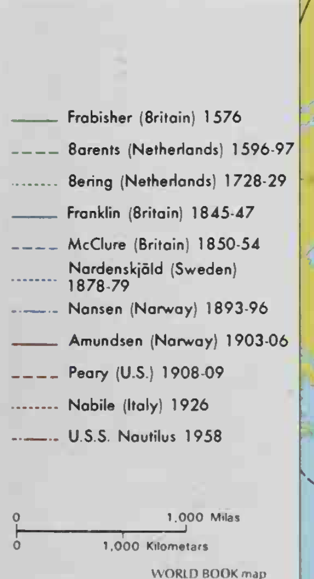
Inuit (sometimes called Eskimos) are the most widespread Arctic people. Their villages spread from northeastern Greenland to the Siberian coast of the Bering Sea. About 47,000 Inuit live in Greenland, 44,000 in Alaska, 35,000 in Canada, and 1,700 in Siberia. The Inuit language is very similar throughout the Arctic.

Americanoids. Several tribes in northeastern Siberia resemble the Indians of the Pacific Northwest so strongly in physical characteristics that scientists sometimes call them *Americanoids.* But their way of life is more like that of the Inuit. These people are also called *Paleo-Siberians,* because they have lived in Siberia so long. Americanoid tribes include the Chukchi, the Koryaks, and the Kamchadals.

The Chukchi live on the Chukchi Peninsula and westward to the Indigirka River. About 3,000 of them live on the coast, where they fish and hunt for seals. Another 9,000 have domesticated reindeer and lead a nomadic life. About 8,000 Koryaks live south of the Chukchi on the Kamchatka Peninsula. Some fish and hunt, and others herd reindeer. The Kamchadals live in southern Kamchatka. Many have married Russians. Fishing provides their main livelihood. They do not herd reindeer.

In the Siberian Arctic. A number of Asian peoples live in the north-central area of Siberia. They include the Yakuts, the Tungus, and the Samoyeds. About 328,000 Yakuts occupy the area west of the Paleo-Siberians. Yakuts in the extreme north own most of the 2 million Asian reindeer. They breed reindeer and dogs for a livelihood. About 60,000 of the total of 75,000 Tungus live along the eastern branches of the Yenisey River. Many of them raise reindeer. About 16,000 Samoyeds, or Nenetz, dwell on the tundra between the Taymyr and Kola peninsulas. They depend largely on reindeer herds for a livelihood, but fishing is also important.

In the European Arctic. A number of Finnic groups live in the Arctic sections of European Russia. They are related to the modern Finlanders, or Suomi. The 250,000 Zyrians form the largest of these groups. In the far north, they lead nomadic lives as reindeer herders. Others hunt, fish, or trade.



About 70,000 Sámi (also called Lapps) inhabit northern Norway, Sweden, Finland, and Russia. Sámi are often considered reindeer herders because they have had domestic reindeer for perhaps 1,000 years. But only about a tenth make their living from reindeer today. The rest work in fishing, lumbering, or other occupations. Sámi speak a language related to Finnish.

Arctic exploration

Pytheas, a Greek, was the first explorer to describe the Far North. In the late 300's B.C., Pytheas claimed he had

Arctic Ocean explorations

Europeans began to learn about the Arctic during the 1500's. This map shows the routes taken by the chief explorers of the Arctic since then.

sailed to an island six days' journey north of Scotland. For hundreds of years, no one believed him. Europeans thought that ice covered everything in the Far North.

Europeans began to learn about the Arctic during the late 1500's. At that time, explorers were trying to find a northeast or northwest passage to Asia (see **Northwest Passage**). In the 1570's, the English explorer Martin Frobisher thought he had found a northwest passage, but he was mistaken. Many other explorers added to the knowledge of the Arctic while seeking a passage, but no one found a successful commercial route. In the early 1770's, Samuel Hearne, an English explorer, became the first white person to reach the Arctic Ocean overland from Hudson Bay. In 1845, an expedition led by Sir John Franklin of Britain disappeared during an attempt to find a commercial route north of North America. Nils A. E. Nordenskjöld of Sweden made the first all-water passage around Europe and Asia in 1878-1879. Roald Amundsen of Norway sailed through the Northwest Passage between 1903 and 1906. But easier commercial routes to Asia had been found long before this.

In the late 1800's, explorers of many nations began to go to the Arctic. Their chief aim was to become the first to reach the North Pole. United States Navy Commander Robert E. Peary; his aide, Matthew A. Henson; and four Inuit are usually credited with winning the race. Peary claimed that he reached the North Pole on April 6, 1909. In 1926, Lieutenant Commander Richard E. Byrd and his pilot, Floyd Bennett, claimed that they flew the first plane over the pole. That same year, Roald Amundsen, Lincoln Ellsworth of the United States, and Umberto Nobile of Italy crossed the Arctic in an airship.

Since 1920, scientists have learned much about the north polar region. For example, Danish and Norwegian expeditions studied Greenland and the Arctic Ocean. Cambridge and Oxford universities, in England, sent many student expeditions to the Arctic. The Arctic Institute of North America, at Montreal, and the Scott Polar Institute at Cambridge University have libraries and publish periodicals dealing with Arctic discoveries.

William Cromie

An Arctic research station operated by United States scientists stands on this drifting mass of sea ice. The man in the foreground is untangling wire to build a radio antenna.

The U.S. atomic submarine *Nautilus* traveled 1,830 miles (2,945 kilometers) under the Arctic ice in 1958. This journey opened a possible undersea route for world commerce across the North Pole, between the Atlantic and Pacific oceans. In 1978, Naomi Uemura, a Japanese explorer, became the first person to reach the North Pole alone. He traveled by dog sled.

In 1984, the Congress of the United States passed the Arctic Research and Policy Act. The act includes plans to organize and fund scientific research, and conservation and development programs.

Arctic Circle, *AHRK tihk* or *AHR tihk,* is an imaginary line that runs through the northern parts of Canada, Alaska, Russia, and Scandinavia. All points on the Arctic Circle lie at 66°30' north latitude, 1,624 miles (2,613 kilometers) from the north geographic pole (see **Arctic Ocean** [map]).

The Arctic Circle marks the edge of an area where the sun stays above the horizon one or more days each year. The sun never sets there on the longest day of summer, about June 21. The sun never rises on the Arctic Circle during the shortest day of winter, about December 21.

At the North Pole itself, the sun is visible 90 days before and 90 days after June 21 if the sky is clear. It stays below the horizon for the same amount of time before and after December 21. See **Midnight sun**.

Stephen S. Birdsall

Arctic fox is a small fox that lives on the treeless coastal areas and islands of the Arctic Ocean. It grows approximately 20 inches (50 centimeters) long, not including its tail, and weighs from 2 to 20 pounds (1 to 9 kilograms).

Arctic foxes have long, thick winter fur to protect them from the extreme cold. Their relatively small ears also keep them from losing too much body heat. Most Arctic foxes change color from brown or gray in summer to white in winter. This color change camouflages the foxes in every season, enabling them to sneak up on prey. One kind of Arctic fox has a light gray or blue winter coat.

Arctic foxes feed mainly on birds, birds' eggs, and such small mammals as lemmings. When food becomes scarce in winter, the foxes often travel great distances to find animal remains left behind by polar bears or wolves. Arctic foxes usually mate for life. During the female's pregnancy, the breeding pair return to their family den, where many generations of foxes have lived before. Females usually give birth to 5 to 10 young each summer. Thomas L. Poulson

Scientific classification. The Arctic fox belongs to the family Canidae. Its scientific name is *Alopex lagopus.*

See also **Animal** (picture: Animals of the polar regions); **Fox** (picture).

Arctic Ocean, *AHRK tihk or AHR tihk,* is the smallest of the world's oceans. It lies north of most of Asia, Europe, and North America. The North Pole is near the center of the Arctic Ocean, and ice covers much of the ocean the year around.

The Greek explorer Pytheas sailed near the Arctic Circle in the late 300's B.C. He reported that a frozen sea lay a six-day voyage north of Britain. The ancient Greeks named the Arctic region for a constellation that they called *Arktos* (the bear). Today, this group of stars, which includes the Big Dipper, is known as Ursa Major or the Great Bear. It appears in the northern sky.

Location and size. The Arctic Ocean lies at the northernmost part of the Earth, above the Arctic Circle. However, not all the seas north of the Arctic Circle are considered part of the Arctic Ocean.

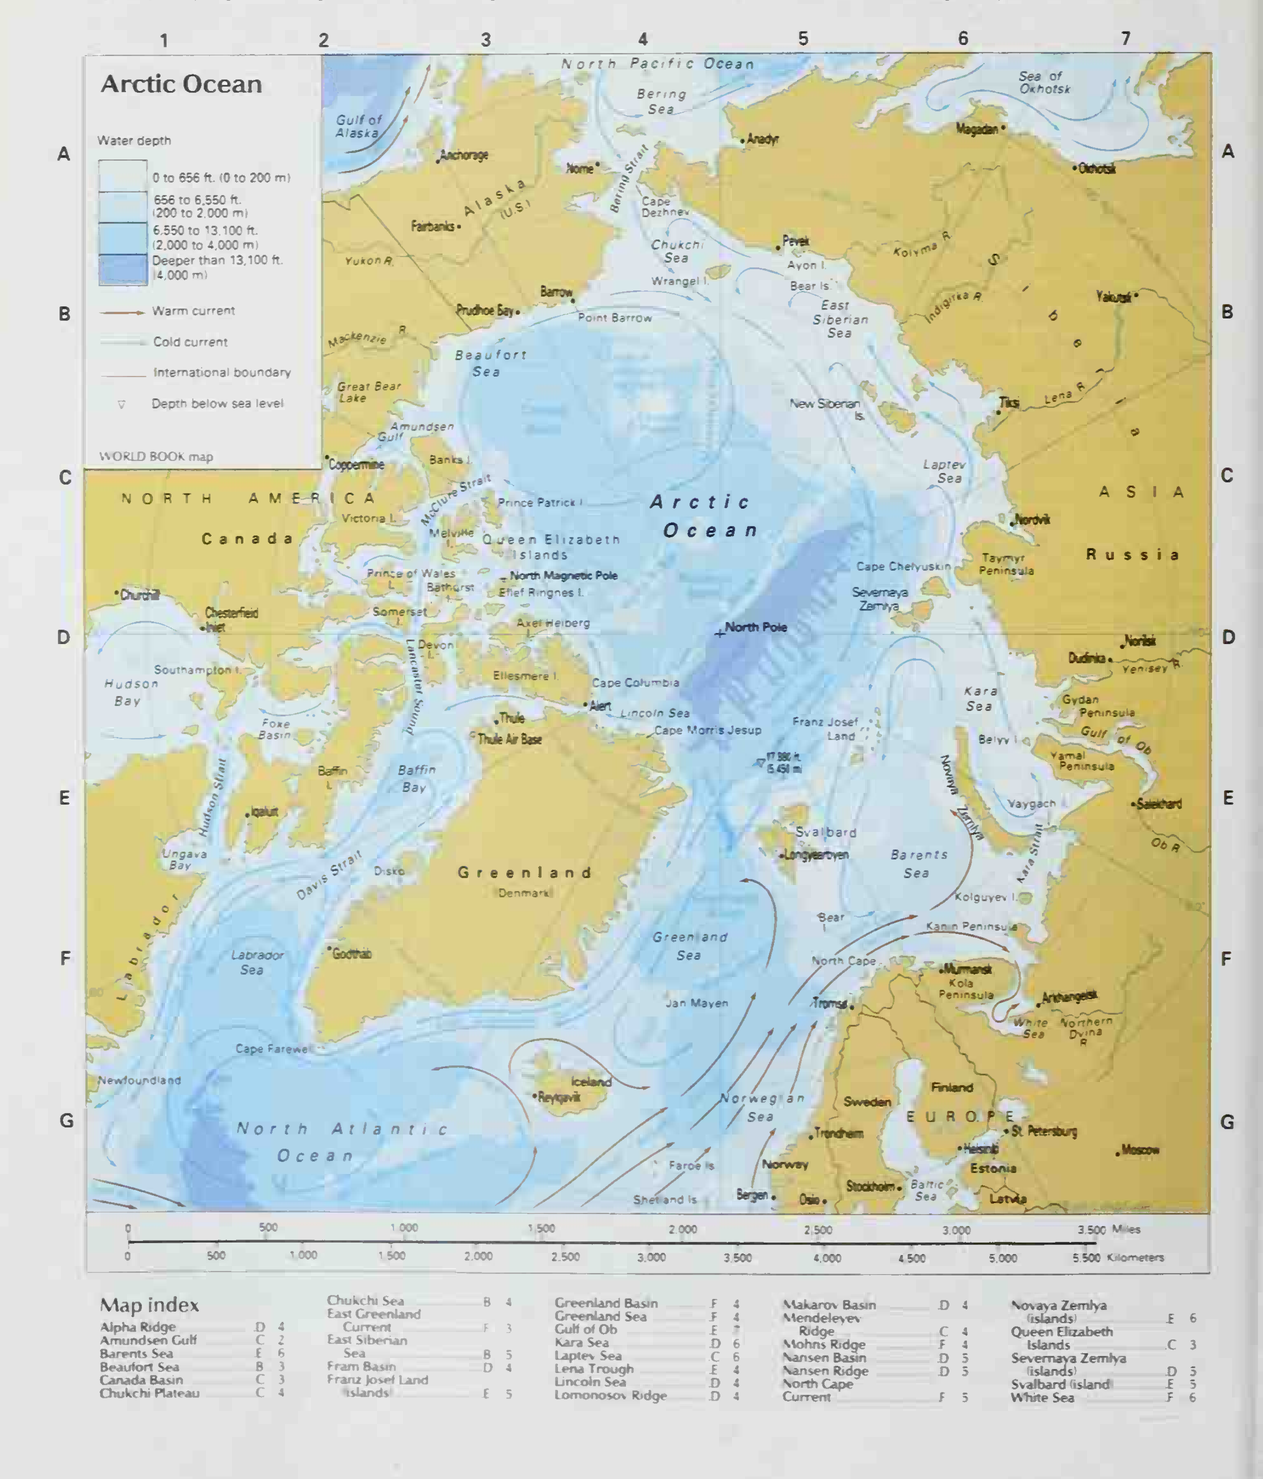
Far northern lands extend into the ocean. They include most of Greenland and parts of Norway, Russia, Alaska, and Canada. For more information on the lands and peoples of the Arctic region, see the *World Book* article on **Arctic**.

Groups of islands divide the coastal waters of the Arctic Ocean into seven seas. These seas, from Greenland eastward, are the Greenland Sea, the Barents, the Kara, the Laptev, the East Siberian, the Chukchi, and the Beaufort. The channels among the northern Canadian islands also form part of the Arctic Ocean. The ocean merges with the Atlantic Ocean south of the Davis Strait, the Greenland Sea, and the Norwegian Sea. The Bering Strait connects the Arctic Ocean and the Pacific Ocean.

The Arctic Ocean covers approximately 4,600,000 square miles (12,000,000 square kilometers). Its widest part lies between Alaska and Norway, a distance of about 2,630 miles (4,235 kilometers). The narrowest stretch is between Greenland and the Taymyr Peninsula of Russia. These areas lie about 1,200 miles (1,930 kilometers) apart.

Facts in brief

Area: About 4,600,000 mi^2 (12,000,000 km^2).
Greatest distance: About 2,630 mi (4,235 km), between Alaska and Norway.
Average depth: 3,950 ft (1,205 m).
Greatest depth: 15,305 ft (4,605 m), north of Svalbard.
Surface temperature: *Lowest,* 28 °F (−2 °C), in January. *Highest,* 29 °F (−1.5 °C), in July.



William Cromie

Ice on the Arctic Ocean breaks up in summer, forming areas of open water called *leads.* Hills of ice, *shown in the center rear,* form when currents and winds push pieces of ice on top of one another. The leads freeze over in fall, and the ice may be 10 feet (3 meters) thick by spring.

Depth and the ocean floor. The Arctic Ocean has an average depth of 3,950 feet (1,205 meters) below the surface of the water. Its deepest known spot—about 15,305 feet (4,605 meters)—is just north of the Norwegian islands of Svalbard.

The floor of the Arctic Ocean includes the *continental shelf* and the *central basin.* The continental shelf is the gently sloping submerged land at the edge of the continents. Most of the continental shelf in the Arctic Ocean lies less than 500 feet (152 meters) below the surface of the water. North of Greenland and North America, the continental shelf extends about 45 to 120 miles (70 to 200 kilometers) from shore. It stretches as far as 1,000 miles (1,609 kilometers) from the Russian coast.

The central basin is divided into two main basins. The Canadian Basin has an average depth of 12,500 feet

(3,800 meters). The Eurasian Basin has an average depth of 13,800 feet (4,200 meters). The central basin has a number of submerged ridges. The Lomonosov Ridge, the tallest, rises about 10,000 feet (3,000 meters) from the deep ocean floor. It extends about 1,100 miles (1,800 kilometers) between a point near Ellesmere Island and an area north of the New Siberian Islands. Two other ridges run parallel to the Lomonosov Ridge. The Alpha Ridge rises on the Canadian side of the Lomonosov. The Nansen Ridge lies on the European side.

The ocean also has a deep trench called the Lena Trough. The trench has a depth of 11,500 feet (3,500 meters) and runs about midway between Svalbard and Greenland.

Climate of the Arctic region is bitterly cold. Surface water temperatures drop to as low as about 28 °F (−2 °C) in January and reach only about 29 °F (−1.5 °C) in July. The sun stays above the horizon for weeks in summer, but winter brings weeks when the sun never rises. The winter sky is often brightened by the flickering or glowing lights of the aurora borealis, or northern lights.

A high-pressure dome of cold, dry air covers the Arctic. It helps prevent the moist, warmer air of the westerly wind from reaching the Arctic Circle. As a result, rain and snowfall over the Arctic Ocean are light. However, fog is common over coastal waters in summer when humid warm air from the land blows out over the coastal ocean. In winter, violent storms called *Arctic hurricanes* form rapidly and unexpectedly in some areas.

Ice covers much of the surface of the Arctic Ocean most of the year. Most of the ice is *sea ice* (frozen seawater), though some *glacier ice* (frozen fresh water) also floats in the ocean. Some sea ice, called *pack ice,* forms in the winter when surface temperatures drop. Seawater forms ice at 29 °F (−2 °C) rather than the 32 °F (0 °C) of fresh water because of its salt content. By March, pack ice covers the entire Arctic Ocean except for the area along the coast of Norway and western Russia to the White Sea. This area is influenced by the warm current called the Gulf Stream. By the end of summer, most of the coastal waters of Russia and mainland North America are ice-free. Most pack ice is less than 6½ feet (2 meters) thick.

Some sea ice remains throughout the year. This *polar ice mass* forms a somewhat jagged circle that has the North Pole as its center and covers about 70 percent of the Arctic Ocean. It rotates in a clockwise direction, driven by the polar easterly wind and ocean currents. The permanent polar ice mass is as thick as 164 feet (50 meters) in some places. In summer, the edges of the polar ice mass sometimes break into sections. These sections are separated by areas of water known as *leads.*

A sheet of glacier ice covers more than 672,000 square miles (1,740,500 square kilometers) of Greenland. This sheet is the largest glacier in the Northern Hemisphere. It reaches a maximum thickness of about 9,800 feet (3,000 meters) near the center of the island, where it lies on land surface. Near the coast, large masses of the glacier break off to form icebergs. Some icebergs float into the North Atlantic Ocean. There, they meet the warm waters of the Gulf Stream and melt. Icebergs so large that they are called *ice islands* come from Ellesmere Island and northern Greenland. Some ice islands are so large and thick that scientists have been able to set up research stations on them.

Currents, water masses, and tides. The North Atlantic Current, which flows north between Iceland and Norway, brings Atlantic water into the Arctic Ocean. It accounts for about 60 percent of the water that enters the icy sea. About 35 percent of the water is supplied by a current that carries water from the Pacific Ocean north through the Bering Strait.

The East Greenland Current carries about 60 percent of the water that leaves the Arctic Ocean. This current flows through the Greenland Sea and passes along the coast of Greenland to the Davis Strait. About 35 percent of the outflow from the Arctic Ocean moves southeastward among the northern Canadian islands. This water joins the West Greenland Current in the Davis Strait, forming the Labrador Current of the northwest Atlantic Ocean.

The Arctic Ocean has four layers of water: (1) Arctic surface, (2) Pacific, (3) Atlantic, and (4) Arctic bottom. These *water masses* differ in saltiness, temperature, or both.

The *Arctic surface water* extends to a depth of about 150 feet (46 meters) and is less salty than the water below it. It has a temperature of about 29 °F (−1.5 °C) in summer and of about 28 °F (−2 °C) in winter.

The *Pacific water* occurs only on the Pacific side of the Lomonosov Ridge beneath the surface water. It extends to a depth of 410 feet (125 meters) and has a temperature of about 30 °F (−1 °C).

The *Atlantic water* lies on both sides of the Lomonosov Ridge. On the Atlantic side, it is just beneath the surface water. On the Pacific side, it is found beneath the Pacific water, which is slightly less salty. The Atlantic water extends to a depth of about 2,800 feet (853 meters). Its temperature is about 35 °F (2 °C).

The *Arctic bottom water* is the saltiest of the Arctic water masses. It extends from the base of the Atlantic water to the seabed and has a temperature of about 35 °F (2 °C).

The Arctic Ocean has relatively smaller tides overall than the other oceans do. The ocean's small size and almost landlocked nature probably account for its slight tidal variations. Most of the tides in the Arctic Ocean rise and fall less than 1 foot (0.3 meter).

Ocean life. Animals of the Arctic include seals, whales, fish, and polar bears. The seals and whales feed on fish and tiny floating plantlike organisms and animals called *plankton.* The plantlike organisms of the plankton are known as *phytoplankton,* and the animals are called *zooplankton.* Large numbers of *diatoms,* a type of phytoplankton, thrive near the surface of waters near the edge of the sea ice. Some whales eat huge amounts of shrimplike zooplankton called *krill.* Shellfish form an important food of walruses (a kind of seal), bearded seals, and sperm whales. Polar bears hunt seals. Such bottom-dwelling fish as cod and halibut are plentiful in the shallow seas along the continental shelf.

The Arctic Ocean has relatively little plant life. Cold temperatures and lack of the sunlight needed for photosynthesis—particularly under the polar ice mass—hinder the growth of plants.

Importance of the ocean. Russian fishing crews catch such fish as cod and halibut in the Barents and

Kara seas. Arctic people of several nations also hunt whales in the Arctic Ocean.

Major deposits of petroleum have been discovered off the north coast of Alaska, and oil wells now operate in this area. The continental shelf near Canada and Russia is also believed to have large reserves of oil and natural gas. Many Arctic islands have deposits of coal.

The Arctic Ocean provides a water route to distant Arctic ports. The ships deliver manufactured goods and other needed products and carry back such goods as fish, fur, and lumber. The ships are accompanied by icebreakers and guided by planes that point out the easiest route through the ice.

Pollution is not a widespread problem in the Arctic Ocean because of the limited development in the region. However, the disposal of wastes from military bases in the Arctic has resulted in some pollution. Oil production on the Alaskan shelf has also produced some pollution. In addition, air pollution from factories in Russia and other northern countries sometimes drifts over the region. Harold V. Thurman

Arctic tern, *AHRK tihk* or *AHR tihk,* is a sea bird often called the migration champion of the world. It migrates over a greater distance than any other bird. The Arctic tern grows about 17 inches (43 centimeters) long; has bluish-gray, black, and white feathers; and has red feet and a red bill. Arctic terns breed on Atlantic seacoasts from New England to Greenland and the northernmost islands of the Arctic Ocean, and on the coasts of the northern North Pacific Ocean and Bering Sea. Late in August, the birds and their young begin a long journey to the shores of Antarctica and nearby islands. Later, the birds fly north once more, arriving in the Arctic about mid-June. George L. Hunt, Jr.

Scientific classification. The Arctic tern belongs to the gull and tern family, Laridae. It is *Sterna paradisaea.*

See also **Bird** (Interesting facts about birds [Greatest traveler]; picture: Birds of the Arctic); **Tern.**

An Arctic tern has bluish-gray, black, and white feathers, along with red feet and a red bill. This far-ranging tern migrates over a greater distance than any other species of bird.

Ardennes Mountains and Forest, *ahr DEHN,* extend from northern France into Belgium and Luxembourg. They contain some of the largest oak and beech forests in Europe. The Ardennes Mountains average about 1,600 feet (488 meters) in height. Coal, iron, and slate have been produced in the northern part of the Ardennes region. The Ardennes Forest was known in Roman times as the *Arduenna.* Fighting occurred in the Belgian and French Ardennes in World War I (1914-1918). In May 1940, the Germans broke through the Ardennes in their invasion of Belgium, during World War II. The Battle of the Bulge took place in the Ardennes in December 1944, during the late stages of the war. See also **Belgium** (The Ardennes). Hugh D. Clout

Ardizzone, *AHR diht ZOH nee,* **Edward** (1900-1979), was a British author and illustrator of award-winning books for children. He wrote many adventure stories that include lively, often humorous drawings. Ardizzone also illustrated over 100 books by other authors.

Ardizzone's most popular books tell about Little Tim, a young boy who lives in a seaside town. *Little Tim and the Brave Sea Captain* (1936) was the first book Ardizzone wrote and illustrated. Other works in the series include *Tim to the Rescue* (1949), *Tim All Alone* (1956), and *Tim's Last Voyage* (1973).

Edward Jeffrey Irving Ardizzone was born on Oct. 16, 1900, in Haiphong, Indochina (now Vietnam). He moved to England with his family when he was 5. Many scenes in the Little Tim books take place on the southeastern coast of England, where he grew up. Ardizzone wrote and illustrated *The Young Ardizzone: An Autobiographical Fragment* (1970). He also gained recognition as a fine painter. Marilyn Fain Apseloff

Area, in plane geometry, is the amount of surface contained within the boundaries of a plane figure. It is generally expressed in square units. For example, a square inch is a square whose sides are each 1 inch long. Other units of area include square feet, square miles, and square meters. The area of most common plane figures can be calculated from certain of their dimensions. Thus, a rectangle's area can be determined by multiplying the lengths of two adjoining sides. The word *area* may also refer to the measure of a curved surface or the measure of the surface of a solid figure. See also **Calculus** (Finding areas); **Metric system** (Use of related units; Non-SI metric units); **Square measure; Weights and measures** (table: Surface or area). Thomas P. Carpenter

Arecibo Observatory, *AHR uh SEE boh,* is an astronomical observatory in Puerto Rico, 50 miles (80 kilometers) west of San Juan. It has the world's most powerful *radio telescope* (a telescope that collects and measures radio waves given off by objects in space). The telescope opened in 1963. Cornell University manages the observatory for the National Science Foundation.

Arecibo's radio telescope has the largest *dish* (bowl-shaped reflector) in the world. The dish is built into a basin-shaped valley and is 1,000 feet (305 meters) in diameter. The dish focuses radio waves onto receivers that hang above it. The waves come from such distant objects as *pulsars* (rapidly spinning stars whose waves arrive on earth as regular pulses). The size of the Arecibo telescope enables astronomers to observe objects that other telescopes cannot detect. Arecibo astronomers discovered the first *binary pulsar* (a pulsar in orbit

David Parker, Science Photo Library

Arecibo Observatory in Puerto Rico has the world's largest reflecting dish. The bowl-shaped surface measures 1,000 feet (305 meters) across and consists of 38,778 aluminum panels. Astronomers use the dish to gather and focus radio waves that arrive from outer space and to transmit and receive radar signals.

around a companion star) in 1974. In the early 1990's, astronomers at the observatory discovered planets beyond the solar system and ice at the poles of Mercury.

In 1996, special mirrors were added to sharpen the telescope's focus. These additional mirrors hang with the radio receivers inside a helmetlike dome above the dish. Astronomers can track an object for several hours by continually repositioning the hanging mirrors. The telescope is also used as a giant radar system to map the surfaces of planets, comets, and asteroids.

In addition, scientists use the telescope to study the regions of the earth's atmosphere that make up the *ionosphere.* These regions have many *ions* (electrically charged atoms and groups of atoms). B. M. Lewis

See also **Telescope** (Radio telescopes).

Arena was the area used for combat with beasts or between gladiators in an ancient Roman amphitheater. Rising rows of stone seats enclosed the space, which was usually oval. The name *arena,* which means *sand* in Latin, came from the practice of spreading sand on the floor to absorb blood. The floor of a Roman arena had passageways underneath for animals or for storage. Arenas today are used for bullfights, concerts, and other events. Arthur M. Eckstein

See also **Colosseum**.

Areopagus, *AR ee AHP uh guhs,* was the oldest and most respected council of ancient Athens. Prominent citizens who held the office of *archon,* one of the highest offices in the Athenian city-state, were members of the Areopagus for life.

In early Athenian history, the Areopagus had administrative and constitutional powers. About 600 B.C., a new group, the Council of the Four Hundred, took over many duties of the Areopagus. About 450 B.C., most of the remaining duties and privileges of the Areopagus were transferred to large people's courts. But the Areopagus continued to try murder cases and retained the power to fine citizens found guilty of extravagance, insolence, or intemperance. The council was named for the Areopagus, or Hill of Ares, where it held meetings.

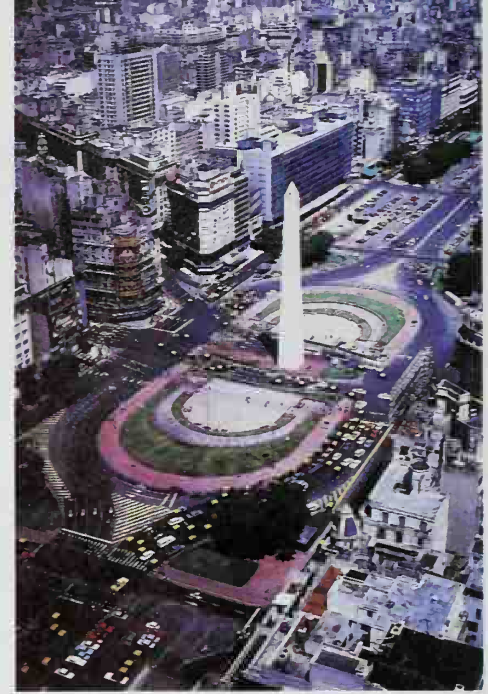
Arequipa, *AR uh KEE pah* (pop. 619,156), is the commercial center of southern Peru and one of Peru's largest cities. It lies 8,100 feet (2,470 meters) above sea level in southern Peru (see **Peru** [map]). Ancient ruins and Indian villages around Arequipa attract many tourists. The Spaniards began settlements at Arequipa in 1540. The city has some of the best examples of Spanish colonial architecture in Peru. Jerry R. Williams

Ares, *AIR eez,* was a god of war in Greek mythology. He was the son of Zeus and Hera, the king and queen of the gods. Ares fathered many children, most of whom were warlike or were associated with war. The Romans identified Mars, their god of war, with Ares. See **Mars**.



Ares probably originated as a fertility god. He was not widely worshiped in Greece, and there are few myths that concern him. He was associated with the Greek goddess Aphrodite. Aphrodite was married to the Greek god Hephaestus, but she had a love affair with Ares. According to some myths, Aphrodite bore some of Ares's children, including Eros, the god of love. In the *Odyssey,* an epic poem attributed to the Greek poet Homer, Hephaestus uses a net to catch Ares and Aphrodite together, embarrassing them in front of other gods.

In poetry, Ares's name has often been used as a synonym for war. However, he was often portrayed as an incompetent warrior. The epic poem the *Iliad,* also attributed to Homer, mocks Ares for being wounded in battle by the mortal hero Diomedes with the help of the goddess Athena. F. Carter Philips

Arethusa, *AR uh THOO zuh,* was a beautiful nymph in Greek mythology. Her father was the sea god Nereus, and she was an attendant of the goddess Artemis. The river god Alpheus fell in love with Arethusa as she bathed in the sea. He pursued her in the form of a swift torrent all the way to an island off the coast of Sicily. Out of pity for the fleeing girl, Artemis transformed her into a spring. Even so, Alpheus overcame her and mingled his waters with hers. The Greeks used this myth to explain the disappearance of the Alpheus River as it flows toward the Ionian Sea. This story is retold in *Metamorphoses* by the Roman author Ovid and in *Arethusa* by the English poet Percy Bysshe Shelley. Nancy Felson

Rural life and city life contrast vividly in Argentina, *as shown here.* Cowboys, called *gauchos,* drive cattle across the open plains of Argentina's fertile Pampa. Modern office and apartment buildings line busy boulevards in downtown Buenos Aires, the nation's capital and largest city.

Argentina

Argentina, *AHR juhn TEE nuh,* is the second largest country in South America in area and the third largest in population. Only Brazil covers a greater area, and only Brazil and Colombia have more people. Argentina has a long, tapered shape and occupies most of the southern part of South America.

The landscape varies dramatically throughout Argentina. The rugged Andes Mountains stretch along the country's western border. A bare, windswept plateau called Patagonia extends across the south. The Pampa, a fertile, grassy plain, lies near the middle of the country. Scrub forests spread across much of the northern part of Argentina.

Buenos Aires, Argentina's capital and largest city, is the nation's leading center of industry, trade, and culture. About a third of all Argentines live in the Buenos Aires metropolitan area. Large parts of the country are thinly settled. Most Argentines are of Italian or Spanish ancestry. Indians—the original inhabitants of what is now Argentina—make up only a small part of the country's population. Nearly all the Argentine people speak Spanish and are Roman Catholics.

Argentina's name comes from the Latin word for silver, *argentum.* The first Spanish settlers came to Argentina in search of silver and gold during the 1500's. The country lacked such riches, but the Pampa's fertile soil later proved to be far more valuable than precious metals. During the late 1800's, Argentina grew wealthy from the export of meat and grain to Europe. By the late 1920's, it had become one of the wealthiest nations in the world. Today, Argentina remains rich in natural resources. However, it no longer ranks among the economic giants.

Manufacturing has become increasingly important to Argentina's economy. Much of the manufacturing involves processing farm products. Argentina is a leading producer and exporter of beef, corn, and flaxseed. It also produces and exports huge quantities of wheat. The country lacks the large supplies of coal, iron ore, and most other minerals needed for heavy industry. However, Argentina's petroleum industry produces nearly all the nation's oil needs.

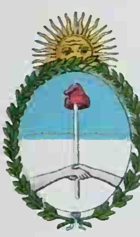
For nearly 300 years, Argentina was a Spanish colony.

Richard W. Wilkie, the contributor of this article, is Professor of Geography at the University of Massachusetts at Amherst.

Facts in brief

Capital: Buenos Aires.
Official language: Spanish.
Official name: República Argentina (Argentine Republic).
Area: 1,073,519 mi² (2,780,400 km²). *Greatest distances*—north-south, 2,300 mi (3,700 km); east-west, 980 mi (1,577 km). *Coastline*—2,940 mi (4,731 km).
Elevation: *Highest*—Aconcagua, 22,831 ft (6,959 m) above sea level. *Lowest*—Valdes Peninsula, 131 ft (40 m) below sea level.
Population: *Estimated 2002 population*—37,919,000; population density, 35 per mi² (14 per km²); distribution, 90 percent urban, 10 percent rural. *1991 census*—32,615,528.
Chief products: *Agriculture*—beef, corn, cotton, flaxseed, grapes, milk, sorghum, soybeans, sugar cane, sunflower seeds, wheat, wool. *Manufacturing*—chemicals, electrical equipment, meat and other food products, motor vehicles, textiles. *Mining*—petroleum, natural gas.
Money: *Basic unit*—peso. One hundred centavos equal one peso.

Argentina gained its independence in the early 1800's and became a republic in 1853. Most of the time since 1930, military dictators have ruled the country.



Government

National government. Argentina's Constitution, which was adopted in 1853, established the country as a republic. The Constitution provides for an elected president and Congress. It places the Roman Catholic Church under government protection and requires that both the president and the vice president be Catholics.

In 1976, a military government took control of Argentina and suspended parts of the Constitution. The military leaders removed the president from office, dissolved Congress, and restricted many civil rights. Political and economic unrest finally forced the military government to call for free elections in 1983. The new civilian government, headed by a president and a Congress, took office in December 1983.

Argentina's president is elected to a four-year term and cannot serve more than two terms. The president appoints members of a Cabinet, who head the executive departments of the government. Argentina's Congress is made up of two houses—the Chamber of Deputies and the Senate. The Chamber of Deputies has 259 members, who are elected by the people. The Senate has 72 members. The provincial legislatures choose the senators.

Symbols of Argentina. The state flag of the government, adopted in 1818, and the coat of arms bear a sun, which represents Argentina's freedom from Spain. The blue and white of the flag are the colors worn by patriots who fought off British invaders in 1806 and 1807. The coat of arms also bears a liberty cap.

WORLD BOOK map

Argentina occupies most of the southern part of South America. It borders five other countries and the South Atlantic Ocean.

Enrique Limbrunner, Plessner International

The Casa Rosada (Pink House) contains the office of Argentina's president and other government offices. The building faces the Plaza de Mayo in the heart of Buenos Aires.

Local government. Argentina is divided into 22 provinces, 1 island territory, and 1 federal district for purposes of local government. Each province is headed by a governor who is elected by the people. The president appoints the governor of the island territory, Tierra del Fuego, which lies off the southern tip of South America. An elected mayor heads the federal district, which includes the capital city of Buenos Aires.

Politics. Argentina's political parties include the Radical Civic Union and the Justicialist Party. The Radical Civic Union, also known as the Radical Party, attracts many middle-class Argentines. The Justicialist Party, also called the Peronist Party, traditionally supported the policies of former President Juan Perón. These policies called for heavy government spending and strong nationalistic feeling. But in the 1990's, the party's policies changed to include support for cutting government spending, expanding trade, and selling state property to private owners. Argentina also has several small parties.

Courts. The president appoints the members of Argentina's Supreme Court, the nation's highest court. The president also appoints judges of the federal courts of appeals. Each province has its own supreme court and lower court system. Provincial governors appoint provincial court judges.

Armed forces. Argentina's president is commander in chief of the country's armed forces. About 65,000 men serve in Argentina's armed forces, which consist of an air force, army and navy. A small number of women serve in noncombat jobs. About 375,000 men serve in Argentina's military reserves.

People

Population. Argentina's population is growing slowly, mainly because of a low birth rate. Immigration contributed greatly to Argentina's population growth in the past. The country had about a million people in the mid-1800's. Huge waves of European settlers helped increase the population to nearly 8 million by 1914. Immigration to Argentina dropped sharply during the 1930's but

picked up again after World War II ended in 1945. Since the 1970's, most newcomers have been political and economic refugees from neighboring countries, especially Bolivia, Chile, and Paraguay.

The population of Argentina is distributed extremely unevenly. About a third of the people live in Buenos Aires and its suburbs. About a fourth of the people live in the Pampa of central Argentina. Large regions of the country have few people because the climate and terrain are unfavorable. These regions include the rugged Andes in the west, the dry Patagonian plateau in the south, and a wooded region in the north called the Gran Chaco.

Ancestry. About 85 percent of Argentina's people are of European ancestry. *Mestizos* (people of mixed Indian and white ancestry) make up most of the remaining 15 percent. Unlike most other Latin American countries, Argentina has few Indians.

About 250,000 Indians may have lived in what is now Argentina when the first Europeans arrived in the 1500's. By the late 1800's, however, many Indians had died of European diseases or had been killed by Europeans. Many others intermarried with the Europeans, producing a mestizo population. Today, Argentina has only

Stockphotos

Argentina's gauchos are typically *mestizos* (people of mixed Indian and white ancestry). The gauchos above wear their traditional costume and keep alive their old songs and dances.

An outdoor lunch in the countryside provides a pleasant change for this Argentine city family. Like most other Argentines, they enjoy large amounts of meat, especially beef.

about 50,000 Indians of unmixed ancestry. Most of them live in isolated areas, such as the Andes, the Gran Chaco, and Patagonia.

People from many European nations settled Argentina. Some Argentines trace their ancestry to the Spaniards who arrived during the 1500's. Others are descended from the millions of Europeans who poured into the country after the mid-1800's. From 1860 to 1930, about 45 percent of Argentina's immigrants came from Italy and about 30 percent came from Spain. Argentina also attracted immigrants from such countries as Austria, Britain, France, Germany, Portugal, Russia, and Switzerland. After 1930, many immigrants came from Eastern Europe, especially Poland, and from the Middle East.

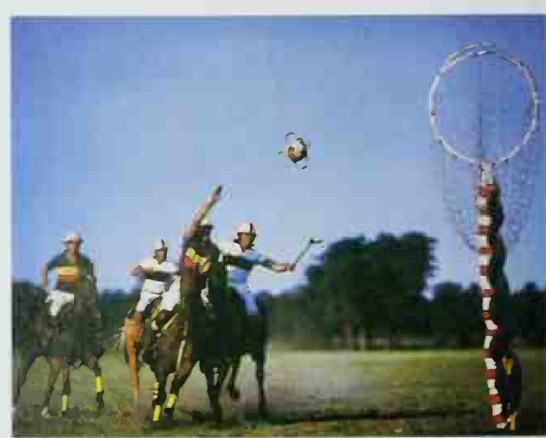
Language. Nearly all Argentines speak Spanish, the country's official language. Many Argentines also speak a second European language and read one of the foreign-language newspapers published daily in Buenos Aires. Some of Argentina's Indians still speak their traditional languages.

Way of life

City life. About 88 percent of Argentina's people live in cities and towns. About 3 million people live in Buenos Aires. About 11 million reside in Greater Buenos Aires, making it one of the largest metropolitan areas in the world. Buenos Aires is the country's chief center of government, commerce, manufacturing, and culture. It lies along the Río de la Plata, a funnel-shaped bay. Argentines call residents of Buenos Aires *porteños,* which means *people of the port.* The nation's next largest cities have fewer than a million people each.

Many European immigrants to Argentina settled in the cities, especially Buenos Aires. The cities offered jobs, education, and other opportunities that enabled newcomers to enter the middle class. Argentina today has a larger middle class than do most other Latin-American countries. Many members of the middle class work in industry, own small businesses, or have government or professional jobs. Some live in tall, modern apartment buildings. Others live in bungalows that have small yards or gardens. Business executives and other wealthy Argentines live in mansions and luxurious apartments in the cities or in fashionable suburbs.

Since the 1930's, many rural workers have flocked to Argentina's big cities to seek work. Today, these cities suffer severe housing shortages, and slums have sprouted on their outskirts. Many slum dwellers live in shacks. Most of them can find only part-time work.



Argentina's urban areas have a European look, reflecting the influence of their European settlers. Many towns and cities are built like Spanish cities around a main square called a *plaza.* A cathedral and important government buildings face the plaza. Buenos Aires resembles a European capital, with its wide boulevards, balconied apartment houses, attractive parks, and impressive government buildings. The city's many cafes, restaurants, and elegant shops draw large crowds. In late afternoon, many porteños stroll along the downtown streets to window-shop and watch other strollers.

Rural life. Only about 12 percent of the Argentine people live in rural areas. Huge ranches, called *estancias,* cover much of the Pampa and Patagonia. Some rural people work on estancias. Others own small farms. In general, country people do not live as well as city people. For this reason, the rural population is declining as farmworkers seek a better life in the cities.

Many rural houses are built of adobe. Poorer people live in huts with adobe walls, dirt floors, and roofs of straw and mud. Larger houses may be built in the Spanish style, with the rooms arranged around a patio. Wealthy landowners have elegant country estates and luxurious city homes.

During the 1800's, some of Argentina's mestizos became cowboys, known as *gauchos.* Gauchos caught wild cattle and horses on the Pampa for their hides. The romantic figure of the gaucho became part of Argentine folklore. Today, the country's few remaining gauchos chiefly work as ranch hands on estancias.

Clothing. Argentine city dwellers dress much like people in the United States and Canada. Some rural people wear distinctive clothing. For example, workers on estancias wear at least part of the traditional gaucho costume. This costume includes a wide-brimmed hat; a *poncho* (blanket with a slit in the middle for the head);

Enrique Limbrunner, Plessner International

Hard-riding horsemen play the popular Argentine game of *pato.* Two teams of riders try to grab a six-handled ball, carry it down the field, and toss it into the opposing team's basket.

Enrique Limbrunner, Plessner International

Argentine schoolchildren in most elementary schools wear uniforms, such as the white smocks worn above. Argentina provides free public elementary and high school education.

and loose trousers tucked into low boots. In northwestern Argentina, Indians wear ponchos, colorful shirts, and derbies.

Food and drink. Most Argentines eat well. Their diet emphasizes meat, especially beef. Argentines prefer beef to fish, chicken, or lamb. Some Argentines eat beef at all meals. The people especially enjoy barbecues, such as *asado con cuero,* in which beef is roasted in its hide over an open fire. Other popular dishes include *pucheros* (stews of chicken or other meat with vegetables) and *empanadas* (pastries stuffed with meat or seafood, eggs, vegetables, and fruit). Italian settlers introduced spaghetti and other pastas into Argentina. The English introduced tea time, which many Argentines observe as they pause for a cup of tea and a snack in the afternoon. Argentina's national beverage is *maté,* a tea brewed from the dried leaves of a native holly tree. Mate is traditionally sipped through a straw from a gourd. Soft drinks have become increasingly popular. Argentines also enjoy the many fine local wines.

Recreation. Great stretches of white, sandy beaches line Argentina's Atlantic coast south of Buenos Aires. Many Argentines enjoy seaside vacations there each year. The southern Andes attract skiers in winter and hikers and hunters in summer. The hill country around Córdoba is also a major vacation area.

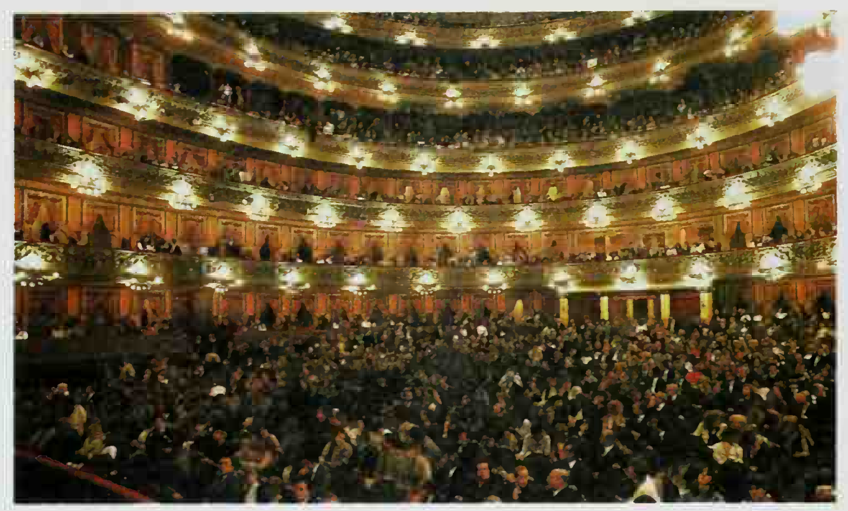
Soccer is Argentina's most popular sport. It draws thousands of fans. Another favorite is *pato,* in which horseback riders try to toss a six-handled ball into a high basket. Other popular sports include basketball, boating, polo, rugby, automobile racing, and horse racing.

Plays and motion pictures draw large crowds in Buenos Aires. The city's famed Colón Theater presents concerts, ballets, and operas. Porteños also enjoy meeting friends in a cafe or restaurant. Argentines celebrate religious festivals with colorful processions and fireworks. During *carnival,* a festival held before Lent, costumed Argentines dance in the streets.

Education. Most Argentines aged 15 or older can read and write. For Argentina's literacy rate, see **Literacy** (table: Literacy rates). Argentina provides free public elementary and high school education. The country also has many private schools, which charge tuition. Children from 6 to 14 years old must attend school. However, only a small percentage finish high school.

Argentina has about 45 universities. The University of Buenos Aires is the largest university in South America. It has more than 200,000 students.

Religion. Spanish colonists brought the Roman Catholic religion to Argentina. Many later immigrants, such as Italians, were also Catholics. Today, about 70 percent of Argentina's people belong to the Roman Catholic Church. However, many of them do not actively practice their religion. Protestants make up about 8 percent of the population. Less than 1 percent of the people are Jews, most of whom live in Buenos Aires. Argentina's Jewish population is the largest in Latin America.



The arts. During the 1800's, the Argentine cowboy—the free-spirited gaucho—became a symbol of the nation and its values. Gaucho legends inspired many writers. *Martín Fierro* (1872, 1879), an epic poem by José Hernández, became a classic of Argentine literature. It tells of a gaucho who rebels against society in defense of his liberty. Some years earlier, Domingo Faustino Sarmiento attacked the legend of the rebel gaucho in *Civilization and Barbarism: Life of Juan Facundo Quiroga* (1845). Sarmiento argued in favor of education rather than rebellion to shape his country's future. During the early 1900's, Benito Lynch and Ricardo Güiraldes wrote imaginative novels about gaucho life.

The gaucho also influenced other Argentine arts. The country's first important painter, Prilidiano Pueyrredón, created popular gaucho scenes during the 1800's. During the early 1900's, the internationally famous classical composer Alberto Ginastera drew upon gaucho songs and dances in his early works, though he gained worldwide recognition for his later experimental operas. Gauchos created many of Argentina's folk dances. But the tango, which the Argentine people regard as their national dance, is based on the dances of a number of

The elegant Colón theater in downtown Buenos Aires ranks as one of the world's finest opera houses. It presents concerts and ballets as well as operas and attracts large, enthusiastic audiences.

countries.

During the 1900's, Argentina's arts have dealt with many subjects besides folklore. Numerous Argentine writers, painters, and composers turned to Europe for new ideas and new forms of expression. They included the poet Leopoldo Lugones, the painter Emilio Pettoruti, and the composer Juan Carlos Paz.

Several Argentine writers became internationally known in the mid-1900's. Jorge Luis Borges, an essayist, poet, and short-story writer, won wide praise for his brilliant use of language and original observations on the meaning of human existence. The novelists Ernesto Sábato and Julio Cortázar explored the difficulties of modern life. A number of Argentine sculptors and painters also gained international recognition during the 1900's. They included the sculptors Julio le Parc and Alicia Peñalba and the painter Romolo Maccio.

The land

Argentina covers 1,073,519 square miles (2,780,400 square kilometers). It stretches about 2,300 miles (3,700 kilometers) from north to south. The southernmost tip of Argentina lies only about 600 miles (970 kilometers) from Antarctica. The northernmost part has a nearly tropical climate. Argentina's landscape includes lofty mountains, arid deserts, vast plains, and swampy forests.

Argentina can be divided into four main land regions. They are (1) Northern Argentina; (2) the Pampa; (3) the Andine; and (4) Patagonia.

Northern Argentina is a lowland plain that lies east of the Andes Mountains and north of the Córdoba Mountains. It consists of two subregions: (1) the Gran Chaco and (2) Mesopotamia.

The Gran Chaco, also called simply *Chaco,* lies between the Paraná River on the east and the lower ranges of the Andes on the west. It spreads northward across Paraguay and into Bolivia. Scrub forests cover much of the Chaco, and few people live in the region. The ground is parched by drought most of the year. But heavy rains fall in summer, causing riverbeds to overflow. Farmers plant corn, wheat, cotton, and other crops in the watered land after the summer floods.

Enrique Limbrunner, Plessner International

Iguaçu Falls, one of the most spectacular waterfalls in South America, forms part of the border between Argentina and Brazil. It is about 2 miles (3 kilometers) wide and plunges 237 feet (72 meters).

Quebracho trees grow in the Chaco, and harvesting the trees is the area's major economic activity. *Quebracho* means *ax breaker* in Spanish. The name comes from the tree's very hard wood, which is used to make telephone poles and railroad ties. The tree is also a source of *tannin,* a chemical used in the leather industry.

Mesopotamia, like its ancient Middle Eastern namesake, is a fertile region between two rivers. The Argentine Mesopotamia, also called Entre Ríos, lies between the Paraná and Uruguay rivers. Along the region's northern border, the Iguaçu River empties into the Paraná. Near the junction of the two rivers, 275 waterfalls form the spectacular Iguaçu Falls.

Mesopotamia has a hot, humid climate. Rolling, grass-covered plains spread across parts of the region. Farmers graze cattle, sheep, and horses on the plains and grow corn, flax, citrus fruits, tea, and rice. Swampy forests cover the extreme northeast. The holly tree whose leaves are used to make the tea called maté grows wild in the region.

The Pampa is a fertile plain that fans out around Buenos Aires. It extends from the Atlantic Ocean to the Andes and covers about a fifth of Argentina. The country's wealth comes mainly from the Pampa, which has some of the world's richest topsoil. Fields of wheat, corn, and alfalfa cover much of the land. Great herds of cattle graze on the drier western Pampa. Farmers also raise flax and hogs on the Pampa.

The Pampa has more than two-thirds of Argentina's people and most of its urban centers, industries, and transportation facilities. In addition to Buenos Aires, several other large cities stand at the edge of the Pampa. Beyond these cities, plains stretch as far as the eye can see. Large estates owned by wealthy ranchers cover much of the thinly settled rural Pampa.

The Andine is the mountainous western region of Argentina. It consists of two subregions: (1) the Andes Mountains and (2) the Piedmont.

The Andes Mountains separate Argentina from Chile. Their highest peaks include the tallest mountain in the Western Hemisphere, Aconcagua. It towers 22,831 feet (6,959 meters) above sea level just inside the Argentine border. A small Indian population raises sheep in an

The Andes Mountains run along the western border of Argentina. The rugged Andes have few settlers. However, small quantities of iron ore and other metals are mined in the region.

area of broad plateaus called the Puna in the northern part of the Argentine Andes. In the south, snow-capped peaks and mirrorlike lakes attract crowds of vacationers who come to ski and hike.

The Piedmont is a region of low mountains and desert valleys east of the Andes. Mountain streams provide water for irrigation and make the Piedmont a productive farming area. Farmers grow sugar cane and corn near Tucumán and alfalfa and cotton near Córdoba. Vineyards near Mendoza and San Juan produce grapes for most Argentine wines. The cities of the Piedmont are the oldest Spanish settlements in Argentina.

Patagonia is a dry, windswept plateau in southern Argentina. It occupies more than a quarter of Argentina but has less than 3 percent of the nation's people. Poor soil and little rainfall make most of Patagonia unsuitable for crop farming. Sheep raising is the region's major economic activity. The sheep ranches are located in canyons that cut across the plateau. The canyons shelter the ranches from windstorms.

Most of Patagonia's people live near its two northern rivers—the Colorado and the Negro. Farmers grow alfalfa, pears, and apples in the river valleys. Wildlife enthusiasts visit Patagonia's rugged coast to see dolphins, penguins, sea lions, and other animals.

John N. Yaeger, West Stock

Ushuaia, one of the southernmost towns in the world, is on Argentina's island territory of Tierra del Fuego. This windswept island lies at the extreme southern tip of South America.

The island of Tierra del Fuego lies at the southern tip of South America. The Strait of Magellan separates it from the mainland. The island is divided between Argentina and Chile. Ushuaia, one of the southernmost towns in the world, is in Argentina's part of the island.

Climate

Argentina has a mild climate. The north has the highest temperatures, and the south the lowest. Argentina lies south of the equator, and so its seasons are opposite those in the Northern Hemisphere. Summer lasts from late December to late March, and winter from late June to late September. January temperatures average about 80 °F (27 °C) in the north and about 60 °F (16 °C) in the far south. Average July temperatures range from 60 °F (16 °C) in the north to 32 °F (0 °C) in the south.

Rainfall is plentiful in northeastern Argentina but decreases toward the west and south. Mesopotamia may receive more than 60 inches (150 centimeters) of rain a year, but the Piedmont and most of Patagonia generally receive less than 10 inches (25 centimeters).

Winds from the Atlantic and Pacific oceans affect Argentina's climate. Moist air from the Atlantic can make summers uncomfortably humid in Mesopotamia and the Pampa. Winds from the Pacific lose most of their moisture over the Andes, leaving the Piedmont and Patagonia dry. Winds from both oceans howl continuously over Patagonia. They warm the plateau in winter and cool it in summer. In winter, air from Antarctica sometimes sweeps northward, bringing cold weather and light snow to Patagonia and the Pampa.

Economy

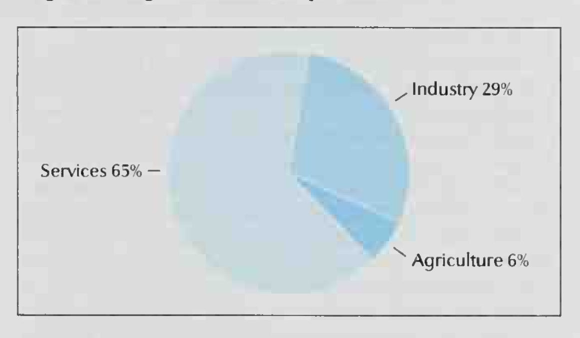
Service industries and manufacturing account for most of Argentina's *gross domestic product* (GDP)—that is, the total value of goods and services produced within a country in a year. However, fertile farmland is the country's most important natural resource and the basis of its economy. Many Argentine factories process farm products, such as beef, wool, and hides. And many of the nation's service industries, such as transportation and banking, depend heavily on agriculture.

Argentina's factories produce most of the nation's consumer goods, including food, clothing, and household equipment. But the country must import much of the heavy machinery and other goods it needs for production.

Service industries. Government agencies have the greatest number of service industries workers. Schools, hospitals, and other institutions that provide community services also employ numerous Argentines. Many other Argentines work for businesses that engage in trade, such as stores, restaurants, and hotels. Other service industries in Argentina include financial institutions and companies in the fields of transportation and communications.

Manufacturing. Buenos Aires and its suburbs have most of the nation's factories. These factories include meat-packing plants, other food-processing establishments, and leather-making companies. Factories in the Buenos Aires area also include plants that manufacture electrical equipment, printed materials, and textiles. Factories located in Córdoba manufacture automobiles, railroad cars, and other transportation equipment. The city of Rosario has oil refineries and plants that produce metal products and chemicals.

Agriculture. The Pampa and Mesopotamia produce most of Argentina's leading farm products. These products are beef, corn, and wheat. Sheep are raised mainly for their wool in dry areas throughout the country. Argentine farms also produce other goods, including citrus fruits, cotton, flax, grapes, milk, potatoes, sorghum, sugar cane, sunflower seeds, and tea.



Argentina's farms vary greatly in size. Huge estates spread over much of the Pampa. Owners of these estates rent land to tenant farmers and hire workers to tend livestock or to help with planting and harvesting. In the north, many families farm small plots and raise only enough to feed themselves. Large landholders own modern equipment. Other farmers rent machinery or use horse-drawn equipment.

Mining. Petroleum is Argentina's most important mineral resource. Oil fields that are located in Patagonia and the Piedmont produce almost all the country's oil needs. These fields also yield natural gas. Argentina produces small quantities of other minerals. Most of the country's metal deposits lie in the Andes and the Piedmont. These deposits include iron ore, lead, zinc, and uranium.

Energy. Hydroelectric plants supply more than a third of Argentina's electricity. Petroleum, coal, and natural gas also provide electric power. Argentina has two nuclear power plants.

Foreign trade. Argentina's main trading partners include Brazil, the United States, and the countries of Western Europe. The development of refrigerator ships in the late 1800's helped Argentina become a leading supplier of food to Europe. Today, farm products make up about two-thirds of the country's total export income. The chief exports include corn, iron and steel, meat, petroleum products, vegetable oils, and wheat. Argentina's

Argentina's gross domestic product

Argentina's gross domestic product (GDP) was $323,548,000,000 in United States dollars in 1997. The GDP is the total value of goods and services produced within a country in a year. *Services* include community, government, and personal services; finance, insurance, real estate, and business services; trade, restaurants, and hotels; transportation and communication; and utilities. *Industry* includes construction, manufacturing, and mining. *Agriculture* includes agriculture, forestry, and fishing.

Production and workers by economic activities

Economic activities	Percent of GDP produced	Employed workers: Number of people	Employed workers: Percent of total
Community, government, & personal services	26	3,965,900	34
Manufacturing	22	1,637,800	14

Meat-packing plants like this one near Buenos Aires contribute heavily to Argentina's industrial output. The country is a leading producer and exporter of beef.

Enrique Limbrunner, Plessner International

Argentina's petroleum industry supplies nearly all the oil the country needs. This oil refinery in La Plata is linked to Buenos Aires by a 45-mile (72-kilometer) pipeline.

leading imports include chemicals and machinery.

Transportation and communication. Railroads, highways, and air routes spread out from Buenos Aires, linking most of Argentina's cities and towns with the capital. The country's roads carry far more people and freight than do the railroads.

Air transportation has grown in importance because of the long distances between Argentine cities. Buenos Aires has two major airports. More than 50 Argentine cities have regularly scheduled passenger flights.

Argentina publishes about 190 daily newspapers. *Clarín,* a privately owned newspaper published in Buenos Aires, has the largest circulation. Almost all Argentine families own one or more radios, and most families own a television set.

History

Early inhabitants. Several groups of Indians lived in what is now Argentina long before the first Europeans arrived in the 1500's. However, the region had relatively few Indians compared with the rest of South America. Tribes in the Pampa and Patagonia roamed the land in search of food. Farming communities developed only in the highlands of the northwest and the tropical forests of the northeast.

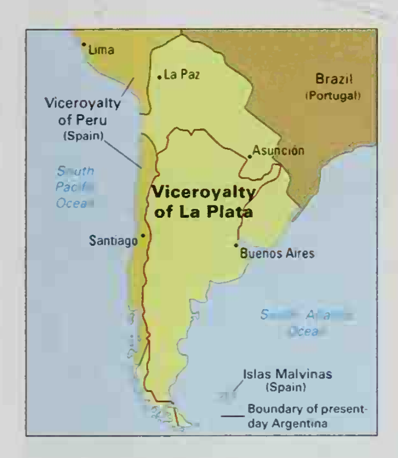
European discovery and settlement. In 1516, the Spanish explorer Juan Díaz de Solís became the first European to reach Argentina. He landed on the shores of the Río de la Plata. In 1536, Spaniards founded a short-lived settlement on the bay. The earliest permanent Spanish settlements in Argentina were made by colonists who came over the Andes Mountains from Peru. During the mid-1500's, they founded Santiago del Estero, Tucumán, and other northwestern mountain towns. Spaniards established Buenos Aires in 1580.

Colonial days. Spain ruled Argentina for nearly 300 years. The earliest Spanish settlers came in search of gold and silver. But after Spain discovered that Argentina lacked such wealth, it largely ignored the colony for years. At first, settlements in the northwest grew more rapidly than Buenos Aires and other coastal towns. The Spanish settlers forced many Indians in the northwest to work for them by farming the land and weaving wool into cloth. The Spaniards brought horses, sheep, and cattle from Spain. Soon, the settlements in northwestern Argentina began to supply mining towns in Peru with food, cloth, and animals.

For many years, the Spanish government limited trade through Buenos Aires, and the city grew slowly. But in 1680, Portuguese settlers established a trading post across the Río de la Plata from Buenos Aires. The Spanish government then encouraged the growth of Buenos Aires in order to protect its colony from Portuguese expansion.

In 1776, Spain created one large colony out of its territories in southeastern South America. This colony was called the Viceroyalty of the Río de la Plata, or simply Viceroyalty of La Plata. It consisted of what are now Argentina, Paraguay, Uruguay, and part of Bolivia, Brazil, and Chile. Buenos Aires became the capital of the viceroyalty and began to thrive as a center of trade.

The Indian population in northern Argentina gradually declined. Many Indians died of European diseases or were killed by Europeans. Others intermarried with the Spaniards, creating a mixed white and Indian population. Indians in the south, however, kept control of Patagonia and most of the Pampa.



Independence. During the early 1800's, the people of Buenos Aires grew more and more dissatisfied with Spanish rule. In 1806 and 1807, British troops tried to seize Buenos Aires to establish a foothold in the region for British trade. The city's residents fought them off without help from Spain, which increased their confidence in gaining freedom from the mother country. In 1807 and 1808, France invaded Spain. The invasions kept the Spanish government busy and gave Buenos Aires a chance to fight for independence.

On May 25, 1810, Buenos Aires set up an independent government to administer the Viceroyalty of La Plata. But the provinces outside Argentina opposed this action and eventually broke away.

Beginning in 1812, José de San Martín, an Argentine general, led the fight against Spain. Under his urging, representatives of the Argentine provinces officially declared the country's independence at the Congress of Tucumán on July 9, 1816. The new country became

Important dates in Argentina

1580	Spaniards established Buenos Aires.
1776	Spain created the Viceroyalty of La Plata.
1810	Buenos Aires formed an independent government.
1816	Argentina declared its independence from Spain.
1853	Argentina adopted a federal Constitution.
1912	The Sáenz Peña Law reformed national elections.
1930	Army officers overthrew the elected government.
1943	Juan Perón began his rise to power.
1955	A military revolt overthrew the Perón dictatorship. Perón fled the country.
1973	Perón returned to Argentina and was elected president.
1974	Perón died. His third wife, Isabel, became president.
1976	Military leaders removed Isabel Perón from office.
1982	Argentina lost a war with Britain over control of the Falkland Islands.
1983	Civilian rule was restored following free elections.

In 1776, Spain created a colony, the Viceroyalty of La Plata, made up of what are now Argentina, Paraguay, Uruguay, and part of Bolivia, Brazil, and Chile.

In 1816, the provinces that now form much of Argentina declared independence from Spain. The new country was called the United Provinces of La Plata.

WORLD BOOK maps

In 1860, Argentina took its present name. It gained territory in the north in 1874 after a war with Paraguay. Patagonia became part of Argentina in 1881.

known as the United Provinces of La Plata. San Martín wanted to expel the Spanish from all South America to prevent future attacks on Argentina. In 1817, he led an expedition across the Andes and surprised the Spanish troops in Chile. After their victory in Chile, his forces helped win independence for Peru. Argentines today honor San Martín as their greatest hero.

Forming a national government. Independence did not bring unity to Argentina. Conflicts arose between the people of Buenos Aires and the large rural landowners. Buenos Aires residents wanted a strong central government, which would be located in their city. But the landowners favored more local authority.

In 1826, a national assembly drew up a Constitution for Argentina. The assembly named Bernardino de Rivadavia, an official in earlier governments, as the nation's first president. Rivadavia resigned in 1827, however, after failing to create a strong national government. Juan Manuel de Rosas, a landowner from the Pampa, ruled Argentina as a dictator from 1829 to 1852. Rosas created a network of secret police to spy on his enemies and led violent campaigns against the Indians of the Pampa. He quarreled in his dealings with other nations. In 1852, General Justo José de Urquiza led an army revolt that overthrew Rosas.

The Constitution of 1853. Delegates from all the Argentine provinces except the province of Buenos Aires met in Santa Fe in 1852 to organize a national government. They drew up a Constitution based largely on that of the United States. The Constitution was proclaimed in 1853 and established a confederation of the provinces. Urquiza was elected confederation president in 1853.

The province of Buenos Aires refused to join the confederation. It prospered as an independent state, helped by good government, large numbers of immigrants, and investment money from Europe. But the provinces of the confederation fared less well. Urquiza tried to force Buenos Aires to join the confederation. In 1859, he defeated a Buenos Aires army led by General Bartolomé Mitre. But in 1861, Mitre defeated Urquiza in another

The Embrace at Maipu (1908), an oil painting by Pedro Subercaseaux; Enrique Limbrunner, Plessner International

José de San Martín became the hero of Argentina's fight for independence from Spain. The great Argentine general also helped win independence for Chile and Peru. In this painting, San Martín, *center right,* is greeted by Chilean General Bernardo O'Higgins after their victory over Spanish forces at the Maipo River in Chile in 1818.

war. The province of Buenos Aires then agreed to enter the confederation on its own terms in 1862. The city of Buenos Aires became the nation's capital, and Mitre was elected president. In 1860, the country had taken the name Argentina.

With the election of Mitre, Argentina began a period of stable government that lasted nearly 70 years. Domingo Faustino Sarmiento succeeded Mitre in 1868 and served until 1874. Both men tried to attract European immigrants and investment to speed Argentina's growth. Sarmiento worked to spread public education.

By the late 1800's, the Pampa had become the heart of Argentina. The last Indians had been driven from the region, and thousands of farm workers from Europe worked the land. British money helped build railroads to carry farm products from the Pampa to Buenos Aires. The first refrigerator ship loaded with fresh Argentine meat sailed from Buenos Aires to Europe in 1877.

Reform movements. During the late 1800's, wealthy Argentines controlled the government and prevented candidates who opposed their conservative views from winning elections. In 1889, dissatisfied Argentines formed the Unión Cívica, an organization that demanded election reform. The Unión Cívica, which later became the Radical Party, appealed to many immigrants and middle-class business people.

In 1910, Roque Sáenz Peña became president. Although Sáenz Peña was a conservative, he pushed election reforms through Congress. The legislation, known as the Sáenz Peña Law, provided for the secret ballot and required every Argentine man 18 and over to vote and to register for army service. The law prevented the large landholders from controlling elections. In 1916, Hipolito Irigoyen, leader of the Radical Party, was elected president in the first honest election under the new law.

Argentina's economy flourished during and after World War I (1914-1918). European countries increased their purchases of Argentine farm products. Immigrants and foreign investment poured into the country. Argentina ranked among the world's wealthy nations in the years before the Great Depression, the worldwide business slump that began in 1929.

Military dictatorships. Irigoyen was again elected president of Argentina in 1928, but he was too ill to govern effectively. The next year, the Great Depression began to shatter the nation's economy. Army leaders removed Irigoyen from office in 1930. Since then, military dictatorships have often ruled the country.

Throughout nearly all of World War II (1939-1945), the Argentine government openly sympathized with the major Axis powers—Germany, Italy, and Japan. However, it declared war on the Axis nations in March 1945, shortly before their defeat.

In 1943, army officers again overthrew the Argentine government. Colonel Juan Perón rose to power while a series of generals served as president. As minister of labor, Perón strengthened the unions. He won the support of urban workers by giving them higher wages, more paid holidays, and other benefits.

Perón was elected president of Argentina in 1946. Perón's second wife, Eva, served as his chief assistant until her death in 1952. Government spending greatly increased under Perón. The government took over many

United Press Int.

Juan Perón rode in triumph with his second wife, Eva, after being reelected president of Argentina in 1952. He was overthrown in 1955 but was again president in 1973 and 1974.

of the nation's industries and discouraged foreign investment. It raised money to try to strengthen manufacturing industries rapidly by taxing farm products. As a result, farm production dropped, and the nation's income fell. But wages continued to rise. Perón suspended freedom of the press and freedom of speech. He had Argentina's Constitution changed to increase his powers and allow him a second term of office.

Perón's power declined during his second term, which began in 1952. He had already made many enemies. Finally, he lost the support of the Roman Catholic Church, after limiting its authority. In 1955, the army and navy revolted, and Perón fled the country. He eventually went into exile in Spain.

Perón's attempt to strengthen manufacturing industries rapidly at the expense of the rural economy caused Argentina to suffer economically. Economic problems of large debts, high inflation, and little growth in productivity developed in the mid-1950's. However, support for Perón's policies continued, especially among labor unions.

New political problems. Military leaders took over the Argentine government after Perón's overthrow. In 1956, they restored the Constitution of 1853. Elections were held in 1958. Arturo Frondizi, leader of the Intransigent Radical Party, became president. Frondizi cut government spending, limited wage hikes, and introduced other measures to curb inflation and reduce the nation's debt. But the people disliked these actions, which called for financial sacrifices.

Army leaders feared Frondizi would yield to pressure from the *Peronistas* (supporters of Perón) and restore Perón's economic policies. They removed Frondizi from office in 1962. A series of civilian presidents and military dictators then ruled until 1972.

During the late 1960's and early 1970's, Argentina's economy worsened due to poor management in government and corruption in the military. The economic decline led to strikes, violence, and antigovernment pro-

tests. Military leaders finally allowed Perón's supporters to return to power in the hope that they could restore order. Héctor José Cámpora, a Peronista, was elected president in 1973. Later that year, Perón returned to Argentina, and Cámpora resigned. Perón was elected president by a wide margin, and his third wife, Isabel, became vice president. Perón died in 1974. Isabel became the first woman president in the Western Hemisphere.

Problems increased after Isabel Perón took office. The inflation rate soared. Terrorism by both conservative and liberal extremists became widespread. In early 1976, military leaders arrested Isabel Perón, took control of the government, and dissolved Congress. They began a campaign to end leftist opposition and terrorism. In the process, thousands were jailed without a trial, tortured, and killed. Many victims have never been found. They are called *los desaparecidos* (the disappeared ones).

Recent developments. In the early 1980's, high inflation, declining production, and heavy government spending all contributed to a deepening economic crisis. The economy was further damaged by a war with the United Kingdom in 1982 over the Falkland Islands. Argentina has long claimed ownership of the Falklands, which lie about 310 miles (499 kilometers) east of the Strait of Magellan. But since 1833, the British have ruled the islands, which Argentines call the Islas Malvinas. In April 1982, Argentine troops seized the Falklands. Argentine and British forces fought air, sea, and land battles for control of the territory. Argentina surrendered in June but did not abandon its claim to the Falklands.

Defeat in the Falklands and mounting economic and political unrest forced Argentina's military rulers to call for free elections in October 1983. Raúl Alfonsín, leader of the Radical Party, was elected president. Alfonsín promised an investigation into the actions of previous governments in the campaign against terrorism. In 1985 and 1986, three former presidents and several high-ranking military officers were convicted and sentenced to prison for their involvement in murders and torture.

Inflation worsened early in 1989. In May 1989, Carlos Saúl Menem, head of the Justicialist Party, was elected president. He introduced an emergency economic program designed to solve the inflation problem. In 1991, his government linked the Argentine peso to the U.S. dollar at a rate of one peso to one dollar. This fixed exchange rate, along with other measures, helped stabilize Argentina's economy and reduce the rate of inflation.

In 1989 and 1990, Menem granted pardons to some people convicted in the mid-1980's for their involvement in murders and torture. Among those pardoned were the three former presidents who had been convicted.

From the 1940's through the 1980's, Argentina's government controlled such key industries as the steel mills and public utilities. During the 1990's, it sold many government-owned businesses to private investors.

Menem was reelected president in 1995. In his second term, the government borrowed heavily, and its debts increased. Domestic interest rates rose, and it became more expensive to do business. As a result, many companies had to close. Many workers lost their jobs. Privatization of businesses also put people out of work.

By the late 1990's, Argentina was in a recession. Tax revenues dropped, and government debt increased. Argentina's exports and foreign investment declined. The fixed peso-dollar rate meant investors and buyers could get more for the same price in other countries.

Fernando de la Rua, leader of the Radical Civic Union, was elected president in 1999. He headed an alliance of his party and the smaller Frepaso Party. In 2000, his government raised taxes and made massive spending cuts.

In late 2001, many people feared that the government would reduce the peso's value. They rushed to banks to withdraw money and convert pesos to dollars. In response, the government limited what people could withdraw each month from their bank accounts. Violent protests broke out, and over 25 people were killed. De la Rua soon resigned. An unsettled period followed, in which three others served temporarily as president. In January 2002, Congress chose Eduardo Duhalde of the Justicialist Party as president. He suspended payments on Argentina's foreign debt and ended the one-to-one peso-dollar link. The peso's value fell sharply, and prices began to rise. Protests continued. Richard W. Wilkie

Argon, *AHR gahn,* is a chemical element that forms 0.94 percent of the earth's atmosphere. Most ordinary light bulbs are filled with argon and a little nitrogen. Argon is also used as a shielding gas in arc welding to protect the metal from oxygen in the air. Lord Rayleigh and Sir William Ramsay discovered it in 1894.

Argon is a colorless, odorless, tasteless gas. It does not react readily with other chemicals. Argon is classed as a *noble gas* (see **Noble gas**). Its symbol is Ar. It has the atomic number 18, and an atomic weight of 39.948. Its freezing point is −189.2 °C, and its boiling point is −185.7 °C. The density is .00166 gram per cubic centimeter at 20 °C at sea level. Argon is continuously released into the atmosphere through the decay of radioactive potassium in the earth's crust. Frank C. Andrews

Argonaut, *AHR guh nawt,* is an eight-armed animal that lives near the surface of warm seas worldwide. It feeds on such animals as small fish. The argonaut swims slowly by forcing a jet of water through its *siphon,* a tube-shaped organ under its head. Female argonauts may reach more than 18 inches (45 centimeters) long.

WORLD BOOK illustration by James Teason
The argonaut is an eight-armed animal that lives in warm sea waters. The male, shown here, is much smaller than the female.

Males rarely grow more than 1 inch (2.5 centimeters) long. The female argonaut builds a fragile, paper-thin shell. Two of the female's arms have broad flaps of skin that release liquid shell material. The shell quickly hardens and is covered by the flaps. Female argonauts reside in the shell and store their eggs there. The name *paper nautilus,* often used for the argonaut, comes from this shell. Male argonauts make no shell.

People once believed that the argonaut sailed on water by using two enlarged arms as sails. It was named after the sailors on the *Argo,* a ship described in the Greek myth of the Golden Fleece. Brian Hartwick

Scientific classification. Argonauts are in the family Argonautidae. The scientific name of the greater argonaut, a common species, is *Argonauta argo.*

Argonauts, *AHR guh nawts,* in Greek mythology, were the companions of Jason, a famous hero. They sailed with Jason on a voyage to capture the Golden Fleece, the golden wool of a flying ram. About 50 of the greatest Greek heroes took part, including Castor and Pollux, Hercules, Orpheus, Peleus, and Telamon.

The Argonauts took their name from their ship, the *Argo.* The ship had been named for its builder, Argos, a famous craftsman. The *Argo* was the longest ship built until that time. The goddess Athena helped in the ship's construction.

After many adventures, the Argonauts found the Golden Fleece in the far-off land of Kolchis. They brought the fleece back to Greece after surviving many dangers on the return voyage. Because of their successful quest, the Argonauts were honored above all other men. In ancient times, it was a mark of great honor to be able to claim that an ancestor had sailed with Jason to find the Golden Fleece. John Hamilton

WORLD BOOK map
The voyage of the Argonauts began at Iolcus. They sailed to Kolchis, where they captured the Golden Fleece. On the return trip, they traveled through much of the Mediterranean area.

Argonne National Laboratory, *AHR gahn,* is one of the largest centers in the United States for research and development in energy technologies. It is located 27 miles (43 kilometers) southwest of Chicago. Argonne has contributed greatly to the development of nuclear reactors (see **Nuclear energy**).

The laboratory is also a center for high-temperature superconductivity materials research. This research deals with ceramics that become *superconducting*—that is, able to conduct electric current without resistance. Other fields studied at Argonne include *artificial intelligence* (computer programs that imitate human thinking) and the effects of energy production on people and the environment.

Argonne began as the University of Chicago's Metallurgical Laboratory, established in 1942 as part of the World War II Manhattan Project to produce the first atomic bomb. In 1946, the laboratory was moved to its present location and renamed Argonne National Laboratory. The University of Chicago operates Argonne for the United States Department of Energy. Argonne also maintains a second site, Argonne-West, at the Idaho National Engineering and Environmental Laboratory near Idaho Falls, Idaho. Toni Grayson Joseph

Argus, *AHR guhs,* was a gigantic monster in Greek mythology. He had 100 eyes and was called *Panoptes,* which means *all-seeing.* The goddess Hera assigned Argus to guard her hated rival, the beautiful Princess Io, a mistress of her husband Zeus (see **Io**). For this reason, the term *argus* is sometimes used to describe a watchful

guardian. Acting on orders from Zeus, the god Hermes killed Argus, thus winning the title *Argeiphontes* (the Slayer of Argus). According to one story, Hera used Argus's 100 eyes to decorate the tail of her peacock.

Argus or Argos was also the name of the faithful hunting dog of the hero Ulysses in the epic poem the *Odyssey.* The dog recognized his master when Ulysses returned home after an absence of 20 years. Argus or Argos was also the builder of the *Argo,* the ship commanded by the hero Jason. Justin M. Glenn

Århus, *AWR hoos,* also spelled Aarhus (pop. 204,139), is Denmark's second largest city. Only Copenhagen has more people. Århus lies on the east coast of the peninsula of Jutland (see **Denmark** [map]). Århus is a busy seaport and a center of industry and commerce. Its major industries include the production of iron, machines, clothing, chemicals, and timber.

Århus developed from a settlement founded in the A.D. 800's. The Cathedral of St. Clemens, built in the 1100's, is a major landmark. An open-air museum on the outskirts of Århus—called Den Gamle By, or The Old Town—displays Danish town houses dating from the Middle Ages. Other sites in Århus include a marble city hall and Århus University. The city also has schools of art, music, dentistry, and journalism. M. Donald Hancock

Arianism, *AIR ee uh NIHZ uhm,* was an early Christian theological view taught by Arius, a priest of Alexandria, Egypt. About A.D. 318, Arius and his followers rejected the doctrine that the three Persons of the Christian Trinity—the Father, the Son, and the Holy Spirit—were equal. Arius denied that Jesus Christ, the Son and second Person of the Trinity, was completely divine. Arius taught that the Son was created by God the Father and was inferior to Him. According to Arius, Jesus was not eternal but was a superior being created by God to redeem the human race. Arius believed that both the Father and the Son were superior to the Holy Spirit.

In 325, the Council of Nicaea condemned Arius's teachings as heresy and affirmed that Jesus was completely divine (see **Nicene councils**). However, the view that Jesus Christ was not truly God continued to be taught in the eastern Roman Empire during the 300's.

The Council of Constantinople condemned Arianism as heresy in 381, and it quickly disappeared within the Roman Empire. But its followers remained active outside the empire. Arian missionaries converted the German tribes of northern Europe to Christianity in the 300's and 400's. After these tribes invaded the Roman Empire, they reintroduced Arianism. Arian teachings received support until the 600's, when the last German tribes were converted to orthodox Christianity. William J. Courtenay

Arias Sánchez, *AH ryahs SAHN chehz,* **Oscar** (1941-), served as president of Costa Rica from 1986 to 1990. He became best known for his work for peace in Central America.

During the 1980's, widespread fighting took place between rebel forces and the governments of Nicaragua and El Salvador. Arias negotiated with other Central American presidents on a plan to promote peace in the region. Their 1987 plan, which was known as the Arias Peace Initiative, called for an end to the fighting in Central America. Arias won the 1987 Nobel Peace Prize for his leadership in developing the plan. However, some Costa Ricans accused him of paying too much attention to foreign affairs while neglecting his own country.

Arias was born in Heredia. He attended the University of Costa Rica, and he taught there from 1969 to 1972. Arias served in the legislature of Costa Rica from 1978 to 1981. He belongs to the National Liberation Party.

Steve C. Ropp

Aries, *AIR eez,* is the first sign of the zodiac. It is symbolized by a ram. Astrologers believe that Aries is ruled by the planet Mars, which is named for the ancient Roman god of war. Aries is a fire sign.

Astrologers regard people born under the sign of Aries, from March 21 to April 19, as active, strong, and fierce-tempered. Arians often seem to be in a hurry. They like excitement and variety, and they tend to lose interest in tasks that require much time. Arians also like to compete and are excellent athletes. In addition, they do well as fire fighters, soldiers, and surgeons and in other occupations that require physical skill.

Christopher McIntosh

Arikara Indians, *uh RIHK uh ruh,* are a tribe that once lived in villages along the Missouri River. They were farmers and buffalo hunters. Today, about 3,000 descendants of the Arikara, the Mandan, and the Hidatsa live on the Fort Berthold Reservation in North Dakota. The three tribes have intermarried so much that they now call themselves the *Three Affiliated Tribes.*

The name *Arikara* comes from an Indian word meaning *horns.* The term refers to the Arikara's custom of wrapping their hair around two pieces of bone so that it stood up like horns. The tribe's name in sign language was *corn eaters.* The Arikara grew corn and traded it to neighboring tribes for buffalo robes and furs.

Corn played an important role in the Arikara religion. The tribe held ceremonies throughout the growing season to ensure a plentiful harvest. They preserved some of the finest ears of corn for many years and honored them as sacred objects. The Arikara lived in earth-covered lodges, each of which housed several families.

In the mid-1700's, French explorers became the first white people to encounter the Arikara. The Arikara were numerous and powerful. They fought frequently with French and American traders and settlers. During the late 1700's, many Arikara died in battles with the Sioux, who finally drove them from their home. Smallpox killed many more members of the tribe in 1837. In 1862, the remaining Arikara settled with the Mandan and the Hidatsa near Fort Berthold in what is now North Dakota. The United States government established the area as a reservation for the three tribes in 1870. Douglas H. Ubelaker

Ariosto, *AH ree AWS toh,* **Ludovico,** *LOO doh VEE koh* (1474-1533), was a poet of the Italian Renaissance. His masterpiece, *Orlando Furioso* (published in 1516, revised in 1521 and 1532), is a long narrative poem depicting the struggle between the Christians and Arab-Muslim tribes called the *Saracens*. Its complicated plot tells stories of knights who travel the world seeking adventure, defending their religious faith, and aiding victims in distress. In the poem, Ariosto perfected the strict eight-line stanza called *ottava rima*. He also perfected the chivalric romance that combines stories about the knights of Charlemagne with those about the knights of King Arthur. He wrote with a robust humor that is present even in the most serious episodes. It influenced the works of such English authors as John Milton, William Shakespeare, and Edmund Spenser.

Ariosto was born in Reggio. In addition to poetry, he wrote satire and scholarly plays. Richard H. Lansing

Aristarchus, *AR ih STAHR kuhs,* of Samos, was a Greek astronomer who lived in the 200's B.C. He was the first to state that the earth revolves around the sun. How he justified this claim is unknown. His writings on the subject have not come down to us, but his idea was quoted by Archimedes, the Greek mathematician. In Aristarchus's surviving treatise, *On the Magnitudes and Distances of the Sun and Moon,* he said nothing about his theory of the earth's motion. A. Mark Smith

Aristide, *AR uh STEED,* **Jean-Bertrand,** *zhahn behr TRAHN* (1953-), became the first democratically elected president of Haiti. He was elected president in December 1990. He took office in February 1991 but was overthrown by military leaders in September. Aristide then fled the country. Despite international pressure, Haiti's military leaders refused to allow Aristide to return. Then, in September 1994, the United States began sending troops to Haiti as part of an operation backed by the United Nations (UN). The operation was designed to force the Haitian military leaders to restore a democratic government on the island. The military leaders soon gave up control of the government, and in October, Aristide returned to Haiti as president.

Haiti's Constitution bans presidents from serving two terms in a row, and Aristide left office at the end of his term in February 1996. But he remained active in politics. He was elected to the presidency again in 2000.

Aristide was born in poverty in Port-Salut, Haiti. He became a Roman Catholic priest in the Salesian Order in 1982. He rose to prominence by speaking out against the dictatorship of President Jean-Claude Duvalier, particularly the oppression of the poor. Aristide's rising popularity made him the target of several assassination attempts by the government. In 1988, the Salesians banned Aristide from preaching, claiming that his teachings advocated violence. Aristide resigned from the priesthood in 1994. Patrick Bellegarde-Smith

Aristides, *AR ih STY deez* (530?-468? B.C.), called the "Just," was an Athenian statesman and military leader. He was a rival of Themistocles, who wanted to make Athens a naval power. Aristides thought it best to maintain a powerful land force because the army, rather than the naval forces, had defeated the Persians at the battle of Marathon in 490 B.C. The issue between them was decided by the people about 483 B.C. According to custom, the Athenians voted on whether Aristides or Themistocles should be *ostracized* (banished). Each voter wrote one of the names on an *ostracon* (piece of pottery). Because of Themistocles's great influence with the people, Aristides lost the vote, and was exiled.

Aristides remained loyal to Athens. In 480 B.C., he warned the city that the armies of Xerxes, king of Persia, were coming. He joined Themistocles at the battle of Salamis, and helped the Greek victory there by forcing the Persians off Psyttalea, an island near Salamis, with troops he had raised (see **Salamis**). He was called back from exile and appointed general in 479. From then on, Aristides was the most powerful leader in Athens. In 477 B.C., the Delian League was formed to free and protect Greek colonies in Asia Minor from Persian rule. Aristides decided the amount of money and number of ships each city should give the league. He decided that each should give according to its ability to pay. Aristides himself served without pay. When Aristides died, the state paid for his burial. Jennifer Tolbert Roberts

See also **Themistocles**.

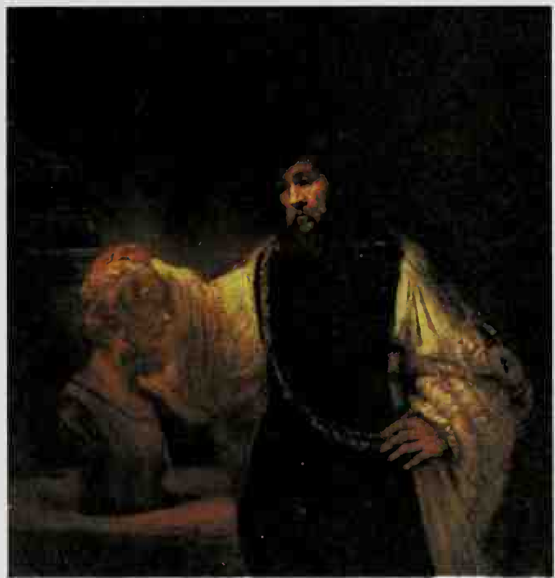
Aristocracy, *AR uh STAHK ruh see,* is a high social class that often used to include the government leaders of a state or nation. Its members claim to be, or are considered by others to be, superior to other people in the society because of family ties, social rank, wealth, or ability. Historically, the word *aristocracy* referred to a form of government controlled by a few wealthy or socially prominent citizens. The word comes from the Greek term meaning *rule by the best*.

Many aristocrats have inherited titles of nobility, such as *duke* or *baron*. These titles were usually given to their ancestors by monarchs because of their wealth or service to the state. In most cases, people were accepted into aristocracy because they owned much land.

In ancient times, aristocracies controlled the governments of Greece and Rome. In modern times, they ruled Britain, Japan, Russia, and Germany. By the time of World War I (1914-1918), the idea that all people are equal had gained influence in many nations through democracy and socialism. As a result, the role of aristocracies in government declined sharply. Alexander J. Groth

Aristophanes, *AR ih STAHF uh NEEZ* (445?-385? B.C.), was the greatest ancient Greek writer of comedy. His plays combine fantasy, rollicking wit, and graceful lyrics with serious criticism of politics, manners, education, music, and literature. He was a master of song and rhythm, and he had a rich imagination.

Aristophanes's comedies provide the best picture we have of Athenian life during its most interesting period. They also provide some of the earliest and best examples of political and social satire. Aristophanes began to produce comedies before he was 20. He wrote more



than 40 plays, and 11 have survived. They are *Acharnians* (425 B.C.), *Knights* (424), *Clouds* (423), *Wasps* (422), *Peace* (421), *Birds* (414), *Lysistrata* (411), *Thesmophoriazusae* (411), *Frogs* (405), *Ecclesiazusae* (393 or 392?), and *Plutus* (388).

Aristophanes' most popular plays are *Frogs,* which criticized Euripides; *Clouds,* which satirized Socrates; *Birds,* a fantasy about a city in the sky; and *Lysistrata,* a partly farcical play in which the women of Greece force their husbands to stop warring against each other.

Luci Berkowitz

See also **Drama** (Old comedy); **Euripides; Socrates.**

Aristotle, *AR ih STAHT uhl* (384-322 B.C.), a Greek philosopher, educator, and scientist, was one of the greatest and most influential thinkers in Western culture. Aristotle was probably the most scholarly and learned of the *classical* or *ancient* Greek philosophers. He familiarized himself with the entire development of Greek thought preceding him. In his own writings, Aristotle considered, summarized, criticized, and further developed all the intellectual tradition that he had inherited. Aristotle and his teacher Plato are usually considered to be the most important ancient Greek philosophers.

Aristotle Contemplating the Bust of Homer (1653), an oil painting on canvas; the Metropolitan Museum of Art, New York City

Aristotle, a Greek philosopher, gazes at a statue of the Greek poet Homer in this painting by the Dutch artist Rembrandt.

Aristotle's life

Aristotle was born in Stagira, a small town in northern Greece. His father, Nichomachus, was the personal physician of Amyntas II, the king of nearby Macedonia. Amyntas was the father of Philip of Macedonia and the grandfather of Alexander the Great. Aristotle's parents died when he was a boy, and he was then raised by a guardian named Proxenus.

When Aristotle was about 18 years old, he entered Plato's school in Athens, known as the Academy. He remained there for about 20 years. Plato recognized Aristotle as the Academy's brightest and most learned student, and called him the "intelligence of the school" and the "reader."

When Plato died in 347 B.C., Aristotle left the Academy to join a group of Plato's disciples living with Hermeias, a former student at the Academy. Hermeias had become ruler of the towns of Atarneus and Assos in Asia Minor. Aristotle stayed with Hermeias for about three years and married the ruler's adopted daughter, Pithias.

In 343 or 342 B.C., Philip II, king of Macedonia, invited Aristotle to supervise the education of his young son Alexander. Alexander later conquered all of Greece, overthrew the Persian Empire, and became known as Alexander the Great. Alexander studied under Aristotle until 336 B.C., when the youth became ruler of Macedonia after his father was assassinated (see **Alexander the Great** [His youth]).

About 334 B.C., Aristotle returned to Athens and founded a school called the Lyceum. Aristotle's school, his philosophy, and his followers were called *peripatetic,* taken from the Greek word meaning *walking around,* because Aristotle taught while walking with his students. See **Lyceum; Peripatetic** philosophy.

Soon after Alexander died in 323 B.C., Aristotle was charged with *impiety* (lack of reverence for the gods) by the Athenians. They probably resented his friendship with Alexander, the man who had conquered them. Aristotle had not forgotten the fate of the philosopher Socrates, condemned to death on a similar charge by the Athenians in 399 B.C. He fled to the city of Chalcis so the Athenians would not, as he said, "sin twice against philosophy." He died in Chalcis a year later.

Aristotle's writings

Aristotle's writings are usually divided into three groups: (1) popular writings, (2) memoranda, and (3) treatises.

The popular writings were mostly dialogues modeled on Plato's dialogues and produced while Aristotle was still at Plato's Academy. These works were intended for a general audience *outside* the school, rather than for philosophers at the school. For this reason, Aristotle referred to them as his *exoteric* writings (*exo-* means *outside* in Greek). These writings have not survived, but the works of later writers include many references to them and quotations from them.

The memoranda were largely collections of research materials and historical records. Prepared by Aristotle and his students, they were intended as sources of information for scholars. With few exceptions, the memoranda, like the popular writings, were lost.

The treatises make up nearly all of Aristotle's surviving writings. They were probably written for use either as lecture notes or as textbooks at the Lyceum. Unlike the popular works, the treatises were intended only for students *in* the school. Thus, the treatises are called Aristotle's *esoteric* works (*eso-* means *inside* in Greek).

Aristotle's philosophy

Logic. Aristotle's works on logic are collectively called the *Organon,* which means *instrument,* because they investigate thought, which is the instrument of knowledge. The *Organon* includes *The Categories, The Prior and Posterior Analytics, The Topics,* and *On Interpretation.* Aristotle was the first philosopher to analyze

the process whereby certain propositions can be logically inferred to be true from the fact that certain other propositions are true. He believed that this process of logical inference was based on a form of argument he called the *syllogism.* In a syllogism, a proposition is argued or logically inferred to be true from the fact that two other propositions are true. For example, from the facts that (1) all people are mortal and (2) Socrates is a person, it can be logically argued that (3) Socrates is mortal. The syllogism continued to play an important role in later philosophy. See **Logic.**

Philosophy of nature. For Aristotle, the most striking aspect of nature was change. He even defined the philosophy of nature in his *Physics* as the study of things that change. Aristotle argued that to understand change, a distinction must be made between the *form* and *matter* of a thing. For example, a sculpture might have the form of a human being, and bronze as its matter. Aristotle believed that change essentially consists of the same matter acquiring new form. In our example, change occurs if the bronze sculpture is molded into a new form.

To better understand change, Aristotle studied its causes. He distinguished four kinds of causes: (1) *material,* (2) *efficient,* (3) *formal,* and (4) *final.* The material cause of the sculpture is the material of which it is made. Its efficient cause is the activity of the sculptor who made it. Its formal cause is the form in which the bronze is molded. Its final cause is the plan or design in the sculptor's mind.

Aristotle studied movement as a kind of change and wrote about the movement of the heavenly bodies in *On the Heavens.* In *On Coming-to-be and Passing-away,* he investigated the changes that occur when something seems to be created or destroyed.

Aristotle's philosophy of nature includes psychology and biology. In *On the Soul,* he investigated the various functions of the soul and the relationship between the soul and the body. Aristotle was the world's first great biologist. He gathered vast amounts of information about the variety, structure, and behavior of animals and plants. Aristotle analyzed the parts of living organisms *teleologically,* that is, in terms of the purposes they serve.

Metaphysics. In his *Metaphysics,* Aristotle tried to develop a science of things that never change and investigate the most general and basic principles of reality and knowledge. Since the most important of these unchanging things is God, Aristotle sometimes called this science *theology,* the study of God. He also called this branch of his philosophy *first philosophy,* because of its fundamental importance. Aristotle himself never used the name *metaphysics,* which literally means *after the physics.* This name was given to the work centuries later simply because it followed the *Physics* in the written edition of Aristotle's works. But the word *metaphysics* has now come to mean any philosophic study of the basic principles of reality and knowledge.

Ethics and politics. For Aristotle, ethics and politics both study *practical knowledge,* that is, knowledge that enables people to act properly and live happily. Aristotle's works on this subject include the *Nicomachean Ethics* and the *Politics.*

Aristotle argued that the goal of human beings is happiness, and that we achieve happiness when we fulfill our function. Therefore, it is necessary to determine what our function is. The function of a thing is what it alone can do, or what it can do best. For example, the function of the eye is to see, and the function of a knife is to cut. Aristotle declared that a human being is "the rational animal" whose function is to reason. Thus, according to Aristotle, a happy life for human beings is a life governed by reason.

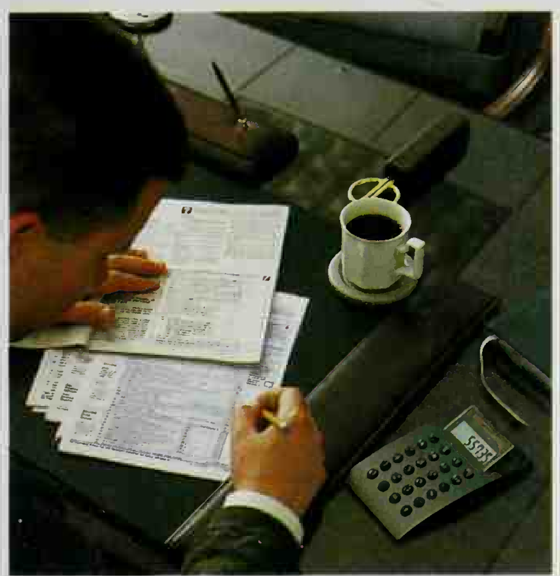
Aristotle believed that a person who has difficulty behaving ethically is morally imperfect. His ideal person practices behaving reasonably and properly until he or she can do so naturally and without effort. Aristotle believed that moral virtue is a matter of avoiding extremes in behavior and finding instead the *mean* between the extremes. For example, the virtue of courage is the mean between the vices of cowardice at one extreme and foolhardiness at the other. Similarly, the virtue of generosity is the mean between stinginess and wastefulness.

Literary criticism. Aristotle's *Poetics* has probably been the single most influential work in all literary criticism. The *Poetics* examines the nature of tragedy, and takes as its prime example Sophocles' tragedy *Oedipus Rex.* Aristotle believed that tragedy affects the spectator by arousing the emotions of pity and fear, and then purifying and cleansing the spectator of these emotions. He called this process of purifying and cleansing *catharsis.*

Aristotle's place in Western thought

After Aristotle's death, his philosophy continued to be taught at the Peripatetic school by a long line of successors. One of these philosophers, Critolaus, went to Rome in 155 B.C. and gave the Romans their first contact with Greek philosophy. About 50 B.C., Andronicus of Rhodes edited Aristotle's works. This edition stimulated much scholarly analysis of Aristotle's philosophy, particularly in Alexandria. From about A.D. 500 to 1100, knowledge of his philosophy was almost completely lost in the West. During this period, it was preserved by Arab and Syrian scholars who reintroduced it to the Christian culture of Western Europe in the 1100's and 1200's.

Aristotle enjoyed tremendous prestige during this time. To some leading Christian, Jewish, and Arab scholars of the Middle Ages, his writings seemed to contain the sum total of human knowledge. Saint Thomas Aquinas, one of the most influential philosophers of the Middle Ages, considered Aristotle "the philosopher." Dante Alighieri, perhaps the greatest poet of the Middle Ages, called Aristotle the "master of those who know."



Aristotle's authority has declined since the Middle Ages, but many philosophers of the modern period owe much to him. The extent of Aristotle's influence is difficult to judge, because many of his ideas have been absorbed into the language of science and philosophy.

Ivan Soll

A calculator can help us with such difficult tasks as filling out a tax return. It is especially helpful in the addition of long strings of numbers and in such operations as multiplication and division.

WORLD BOOK photo by Steven Spicer

A pen or pencil remains the instrument of choice for many people when it comes to simple arithmetic, such as the addition and subtraction operations that keep a checkbook up to date.

Arithmetic is the process of calculating by means of symbols called *numerals.* It is the part of mathematics that concerns how to get answers to addition, subtraction, multiplication, and division problems. The word *arithmetic* comes from the Greek word *arithmos,* which means *number.*

Mathematicians use the term *number* to mean an idea having to do with the amount or quantity of a thing or things. They use *numeral* to mean a symbol that represents a number. For example, the numerals 6 and VI stand for the number also represented by the word *six.* But in everyday language, *number* is also used to mean *numeral.* The rest of this article uses *number* in the everyday way.

Many people use computers and calculators to do most of their arithmetic, but much arithmetic is still done with pencil and paper. Both methods of calculating rely on a *numeration system* (a system of counting and naming numbers) that determines the value of a digit by its position in a number.

The numeration system used by most people is called the *decimal* system, or *base 10* system. In this system, a *digit* is any one of the symbols 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9. Each position in a number with two or more digits has a value 10 times greater than the position to its right. And each position has a name that corresponds to its value. The positions, from right to left, are called the *ones'* position, the *tens'* position, the *hundreds'* position, the *thousands'* position, and so on. Each position has only one digit.

A computer or calculator does the actual arithmetic with another numeration system, the *binary system.* However, in this approach, the user enters the problem in the decimal system, and the results are shown in the decimal system. This article describes various pencil-and-paper procedures for calculating with the decimal system.

Addition

Several methods of addition are in use today. Methods A through C shown here work from right to left. In the United States and Japan, many people use method A. When a column of numerals adds up to 10 or more, write the digit in the tens' place above the column to the left. In the example, in the ones' column, 7 + 6 = 13. Take one 10 from the 13 and write it as 1 above the tens' column. In the hundreds' column, when you add 8 hundreds and 6 hundreds, you get 14 hundreds. Because 10 hundreds equals 1 thousand, take 10 from the 14 hundreds and add 1 above the thousands' column.

Method B is similar to method A except that you add the 1 to the top number instead of just writing the 1 above the column. Then you have to add only two numbers, which for most people is much easier than adding three. In the tens' column, the 4 becomes a 5 when you add the one 10 from the ones' column.

In method C, all the answer is kept together on or below the line instead of part of it moving above the columns. If the sum of a column is 10 or more, write 1 on the line and then add it to the sum of the next column. In this example, you move one 10 from the 13 in the ones' column into the tens' column on the line. In the tens' column, after adding 4 and 3 for a sum of 7,

Addition methods (A to C)

A.	B.	C.
1 1 (above 2 and 4)	3 5 (above crossed-out 2 and 4)	
2847	2847	2847
+3636	+3636	+3636
6483	6483	6483 (1 1 on the line)

you add the 1 to the 7 for a total of 8. Method C is easier than method A because you add the two numbers you see above the line and than just increase the sum by 1.

Method D does not require working from right to left. First, add each column. Write the sum at the bottom of each column. In the next step, modify any two-digit answer by adding the number in the tens' position into the position to the left. For example, take 1 thousand—that is, 10 hundreds—from the 14 hundreds and add it to the thousands' column. The total in the thousands' column then becomes 6.

In method E, you add from left to right without writing the numbers carried to the next column. Many Europeans learn method E. Before they write a sum in a column, they look at the next column to the right to see whether it adds up to 10 or more. If it does, they increase the sum of the column on which they are working by 1.

Methods F through H are commonly used by people who have not learned formal calculation techniques. Many people use these methods without writing down any of the steps. In method F, you first add the values in each position—the ones, tens, and so on. Then add the sums for all the positions to get the final answer.

Method G breaks down the process further. You add the numbers in the position of highest value first. In this case, add the 40 from the 47 and the 30 from the 35: 40 + 30 = 70. Then add the 7 from the 47 for a total of 77. Finally, count on the remaining 5 from the 35.

In method H, you adjust numbers to make them easier to add. Increase the 47 by 3 to 50. To balance the increase, decrease the 35 by 3 to 32. Then add 50 to 32.

Addition methods (D to H)

D.
```
  2 8 4 7
+ 3 6 3 6
---------
 5 14 7 13
  6 4 8 3

E.
```
  2847
+ 3636
------
  6483
```

F. 47 + 35 = 70 + 12 = 82

G. 47 + 35 = 40 + 30→70→77→78, 79, 80, 81, 82

H. 47 + 35 = 50 + 32 = 82

Subtraction

In method A shown here, you change top numbers to make them larger than bottom numbers. Then you can easily subtract all the bottom numbers from the top numbers. In the example shown, the bottom number in the ones' column, 7, cannot be subtracted from the top number, 3. So you take one 10 from the top number in the tens' column and add it to the ones' position in that number. This addition changes the number in the ones' position from 3 to 13. In the hundreds' column, you cannot subtract 8 hundreds from 4 hundreds. So you make the 4 hundreds bigger by adding to it one of the thousands, or 10 hundreds, to make 14 hundreds.

Method A can be used in two ways. In the easier way, you adjust top numbers so that every top number is larger than the number below it. Then you do all the subtraction. You can work from left to right or from right to left. In a more difficult technique, you work one column at a time, starting at the right. You adjust the top number if necessary, then subtract. Schools in the United States commonly teach this technique.

A comparison of subtraction method A and addition method D shows how addition and subtraction are opposite procedures. When doing addition, you can get too many digits in one position and therefore have to add one 10 of the quantity corresponding to that position to the place to the left. When doing subtraction, if you do not have a large enough number from which to subtract, you have to take one 10 of the quantity corresponding to that position from the place to the left.

Method B is similar to method A, but when you take 10 from the left position, you write it as 10. There are two ways to use method B. In the example shown, if you split the 7 in the ones' column into 3 and 4, you can easily subtract 3 from the 3 to get 0. Then you can subtract the 4 from the 10, which leaves 6. Another approach is to take the entire bottom number from the 10: 10 − 7 = 3. Then add the difference from that subtraction to the top number: 3 + 3 = 6. Method B comes from Korea.

Method C uses *equal additions*. You add the same amount to the top and bottom numbers so the difference between them stays the same. Schools in Latin America and many European countries teach method C. However, students in some countries do not write the 1's in the top number.

In this method, you add 10 ones to the ones' position in the top number to make 13. Then you subtract 7 from 13 to get 6. To balance the 10 ones that you added, you add one 10 to the bottom number in the tens' column. Write a 1 representing the 10 beside the 4 in the tens' position. In the tens' column, first subtract 4 from 8: 8 − 4 = 4. Then subtract the 1: 4 − 1 = 3. In the hundreds' column, add 10 hundreds to the 4 hundreds in the top number to get 14 hundreds. Then add 1 thousand to the 2 thousands in the thousands' column.

Methods D and E involve working with numbers that have the same value positions. In method D, you subtract the 200 of the 278 from the 600 of the 634 to get 400. Then, you subtract the remaining 78 from 400 to get 322. Finally, you add to the 322 the 34 left over from the 634 for an answer of 356.

Method E is similar to addition method H. You adjust the numbers to make them easier to use. Adding the same amount to both numbers does not change the difference between them. By adding 2 to both numbers,

Subtraction methods (A to E)

A.
```

  6  4 8  3
- 2  8 4  7
-----------
  3  6 3  6
```

B.
```
  5 10 7 10
  6  4 8  3
- 2  8 4  7
-----------
  3  6 3  6
```

C.
```
  6 ¹4 8 ¹3
-¹2  8 ¹4 7
-----------
  3  6  3 6
```

D. 634 − 278 = 400 − 78 = 322 + 34 = 356

E. 634 − 278 $\underset{+2}{=}$ 636 − 280 = 20 + 300 + 36 = 356

you get 636 and 280. The number 280 is easier to work with than 278. To count up from 280 to 636, you first count 20 to get to 300, then 300 to get to 600, and then 36 to get to 636. Then add the numbers 20, 300, and 36 for the total difference.

Multiplication

You can multiply by adding repeated copies of a number. Method A requires only that you multiply by 10, 100, or 1,000, and so on, and then add the resulting multiples. Multiplying by 10 moves a number one value position to the left. So 10 times 486 is 4,860. Multiplying by 100 moves each number two value places to the left. So 100 times 486 is 48,600. So 324 × 486 is just four copies of 486, two copies of 4,860, and three copies of 48,600. Add all of these copies together to find the final answer, called the *product*.

In method B, you multiply each digit in the top number, called the *multiplicand*, by each digit in the bottom number, called the *multiplier*. In this example, 486 is the multiplicand and 324 is the multiplier.

Method C is a shortcut of method B in which you multiply the entire multiplicand by each number in the multiplier. You begin on the right. In the example shown, first multiply 486 by 4. Then multiply 486 by the number in the tens' position in the multiplier: 20 × 486. And then multiply 486 by the number in the hundreds' position in the multiplier: 300 × 486. Schools in the United States teach method C.

Egyptians used method D more than 2,000 years ago. To use this doubling method, sketch a table with two columns. In the right column, write the multiplicand on top, double it, and write the doubled figure below it. Double this second number and write it as the third number in the column. In the left column, write 1 on top, double it to 2, and write the 2 below the 1. Then double the 2 to 4 and write the 4 below the 2. Continue in this manner until the next number you would write in the left column is bigger than the multiplier.

Then, choose the numbers in the left column that add up to the multiplier. Finally, add the corresponding values from the right column. For example, to multiply 486 by 324, add the values for 256, 64, and 4 because 256 + 64 + 4 = 324. The result is the following: 124,416 + 31,104 + 1,944 = 157,464.

Method E has been used in Arab nations, China, India, Japan, and Western Europe. First, draw a rectangle and divide it into rows and columns. Divide each resulting square by a diagonal line running from top right to bottom left. Write the multiplicand, 486, across the top, and the multiplier, 324, down the right side. Write the product of each row and column in the square for that row and column. Place the tens part of the product in the top triangle and the ones part in the bottom triangle.

Then add from right to left. Begin by writing below the square the number in the lower right triangle—in this case, a 4. Then, add the numbers in the diagonally arranged group of triangles that are above and to the

      4    6    4                       4    6    4
```

left—in the example, the three 2's. You continue in this manner. If a sum has two digits, write the tens' digit above the top triangle of the next group. Include that digit when you calculate the sum for that next group.

In the example, the shaded 2 + 2 + 2 = 6 consists of the first group of triangles and its sum. The shaded 2 + 1 + 4 + 1 + 8 + 1 = 7 consists of the tens' digit from the second group (the 2), the numbers in the entire third group (the 1, 4, 1, 8, and 1), and the ones' digit of the sum of those six numbers (the 7). The answer to the problem runs from the square's top left side to its bottom right.

Division

Method A shows the basic method of division. In this method, you take away copies of the *divisor* (the number by which you are dividing) in multiples of 1, 10, 100, and so on. You continue taking away copies until you use up the *dividend* (the number you are dividing) and therefore cannot take away any more copies. The answer is called the *quotient*. There is also usually an amount left over called the *remainder*. Method A for division is the opposite of method A for multiplication.

Method B resembles division method A, but you take away more than one set of each multiple at a time. You do not need to take away all the sets of a given size in the first try. In the example shown, 3 sets of 100 copies of the divisor could have been taken away in the first try. But actually, 2 sets of 100 copies, then 1 set of 100 copies, were taken away.

In method C, you must take away all the sets of a given size in the first try. In the example, you must begin by taking away 3 sets of 100 copies of the divisor. Schools in the United States usually teach method C.

Method D is an abbreviation of method C. It comes from Argentina and other Latin American countries. Write the divisor on the right, the dividend on the left, and the quotient below the divisor. When you subtract from the dividend, write down only the answer to that subtraction.

Method E became widespread in Europe in the 1400's. It began in India, where the calculations were written in sand. Method E resembles method C, except that you write the results of subtraction above the dividend instead of below. This method is shown in three steps to show how it works. The work for each step is shaded. Each number is scratched out as it is used.

In the first step, multiply 486 by 3. Write the first part of the quotient—3—to the right and the answer—1,458—below the dividend. Then subtract 1,458 from 1,574. Work from left to right (5 − 4 = 1 and 7 − 5 = 2), writing the remainder above the dividend. To make a subtraction in the hundreds' column, you need to change the thousands' column. Take 1 from the 2, crossing out the 2 and writing the resulting 1 above it. The 1 that you took away from the thousands' column becomes a 10 in the hundreds' column. Mentally add the 10 to the 4 in the hundreds' column, then subtract 8 from 14.

Arithmetic of small fractions

The addition and subtraction of fractions that are smaller than 1 is similar to the addition and subtraction of *whole numbers* (numbers that are not fractions). There is a major difference, however, between the multiplication and division of fractions less than 1 and the multiplication and division of whole numbers.

In multiplication, when the multiplier is a whole number larger than 1, the product is larger than the multiplicand. For example, $2 \times 3 = 6$. However, when the multiplier is a fraction less than 1, the product is smaller than the multiplicand. This result occurs because multiplying a number by a fraction less than 1 means taking a part of that number. For example, $\frac{1}{2} \times 3$ means taking one-half of 3, which is smaller than 3.

In division, when the divisor is a whole number larger than 1, the quotient is smaller than the dividend. For example, $6 \div 3 = 2$. However, when the divisor is a fraction less than 1, the quotient is larger than the dividend. This result occurs because dividing a number by a fraction less than 1 means finding out how many of that fraction are in the number. For example, $3 \div \frac{1}{2}$ means, "How many one-halves are in 3?" There are 6, and 6 is a bigger number than 3.

Arithmetic of negative numbers

Negative numbers help describe things that have opposite values, such as wins and losses or income and ex-

penses. Negative numbers also help describe measurements whose amounts are opposite in direction—temperatures above and below zero degrees or heights above and below sea level. One value or direction is considered to be positive and the opposite value or direction negative. Positive numbers have a plus sign; negative numbers, a minus sign.

Because negative numbers are the opposite of positive numbers, the arithmetic of negative numbers differs from that of positive numbers. Adding two positive numbers makes a bigger positive number, and adding two negative numbers makes a bigger negative number. But when a positive number and a negative number are added, the smaller number cancels that much of the bigger number. Whether the sum is positive or negative depends on the sign of the bigger number. If the bigger number is positive, the sum is positive. If the bigger number is negative, the sum is negative. Adding a negative number is equivalent to subtracting a positive number of the same size.

Subtracting a negative or a positive number from a number of opposite sign is the same as adding the opposite kind of number. For example, $10 - (-5) = 15$ just as $10 + 5 = 15$. And $-10 - (+5) = -15$ just as $-10 + (-5) = -15$. Therefore, subtraction does not always result in a smaller number. If you subtract a negative number from a positive number, you will get a larger number because taking away the negative value provides that much more of the positive value.

Multiplying by a positive number can be thought of as repeated addition. Repeatedly adding a negative number results in a larger negative number: $8 \times (-3) = -24$. Multiplying by a negative number can be thought of as repeated subtraction. Repeatedly subtracting a positive number also gives a larger negative number $-3 \times (+8) = -24$. However, repeatedly subtracting a negative number gives a positive number. Thus, when the signs of the numbers are opposite, a negative number results. When the signs are the same, a positive number results.

Division is the opposite of multiplication. Therefore, to determine the sign of a quotient, you can convert the division problem to a multiplication problem. For example, you can convert $-24 \div 8 = ?$ to $8 \times ? = -24$. You know that multiplying a positive number by a negative number results in a negative number. Thus, the number represented by the question mark in the multiplication problem—and the division problem—must be negative.

General rules for division are: Dividing opposite kinds of numbers, one positive and one negative, results in a negative quotient. Dividing like kinds of numbers, both positive or both negative, yields a positive quotient.

History

Calculation tools. During most of human history, few people used written numbers to calculate. Many numeration systems were difficult to use, especially for multiplication and division. Writing materials were also expensive until the mid-1800's, when machine-made wood pulp paper became available.

Most ancient people used calculating objects, such as pebbles and sticks. An individual manipulated the objects on a board, a cloth, or some other surface. Lines drawn on the surface helped the individual distinguish columns or rows that had different numerical values.

People living in western Africa used a type of small seashell called a *cowrie shell* for their calculations. The Inca of South America calculated with kernels of wheat on a board. The ancient Greeks and Romans used stones on wood or marble tables. The Chinese and Japanese used small bamboo or wooden reckoning sticks on a board divided into columns. Later, the use of an *abacus,* a counting device with beads fastened on rods, became widespread in Asia and Russia.

Mechanical calculators that used gears began to appear in Europe in the 1600's. In the 1940's, scientists and engineers built electronic calculators using vacuum tubes. As smaller electronic components were developed, electronic calculators became smaller, faster, and cheaper. By the early 1990's, inexpensive handheld calculators were available throughout the world.

Written arithmetic methods. The decimal system of numeration made written calculations easy to perform. This system evolved in India sometime between A.D. 600 and 900. Indian and Arabic scientists and mathematicians devised a variety of arithmetic methods based on the decimal system. By 1000, the Arabs had spread these methods throughout their empire, and the methods had begun to filter into Europe.

The development of the printing press in Europe in the mid-1400's enabled printers to produce inexpensive books. As a result, arithmetic books written in the languages of the common people soon became available. Prior to that time, arithmetic was taught mostly in universities, which used the Latin language. By the 1800's, young children were learning arithmetic in school in their own language.

Today, the availability of calculators makes it seem unnecessary for older students to memorize and practice complicated arithmetic procedures. But it is important to know how to determine whether an answer obtained on a calculator is reasonable. Karen Connors Fuson

Arithmetic progression. See Progression (Arithmetic progression); Series.

Arius, *AIR ee uhs* or *uh RY uhs* (A.D. 256?-336), was a priest of Alexandria, Egypt, who founded an early Christian theological view called *Arianism.* About A.D. 318, Arius challenged the doctrine that the three Persons of the Christian Trinity—the Father, the Son, and the Holy Spirit—were equal. Arius taught that God the Father ranks above the Son, who is Jesus Christ, and that both rank higher than the Holy Spirit.

In about 318, Bishop Alexander of Alexandria condemned Arius's teachings as heresy and excommunicated him. But Arius continued to teach and attracted many followers. To settle the dispute, the Roman emperor Constantine the Great called a general church council in Nicaea (in what is now Turkey) in 325. The council also condemned Arius's views. It issued the Nicene Creed, which states that the Son is fully divine and is equal to the Father. William J. Courtenay

See also Arianism; Nicene Councils; Trinity.

Bill Ross, West Light

Organ-pipe cactus, *right foreground,* grows in a desert in southern Arizona. The desert, part of Organ Pipe Cactus National Monument, has plant and animal life found nowhere else in the United States. Arizona's natural beauty is preserved in numerous national parks and monuments.

Arizona *The Grand Canyon State*

Arizona, once thought to be an almost worthless desert, has become a prosperous state of the United States. It is rich in farm and mineral products, and it is growing rapidly in manufacturing and population. Vast irrigation systems transform the desert soil into rich farmland. Dams built by the government or with federal funds provide water to irrigate large areas of land. These dams also generate electric power for the state's cities and industries.

Although the desert summers are very hot, Arizonans stay comfortable. They live in air-cooled homes, work in air-conditioned factories, and travel in air-conditioned automobiles.

The desert winters are warm and pleasant. Arizonans, along with thousands of vacationers, enjoy the desert sun while winter chills other parts of the United States.

Arizona's climate attracts so many people that the state has become one of the nation's fastest-growing areas. Between 1950 and 2000, Arizona's population grew by almost seven times.

Most of Arizona's people live in desert areas, but more than half the state is mountain and plateau country. These higher, cooler areas have the largest ponderosa pine forest in the United States. Large herds of cattle graze in these regions.

The northwestern part of the state has one of the greatest scenic attractions in the United States—the mighty Grand Canyon of the Colorado River. Arizona's other scenic wonders include the Painted Desert, the Petrified Forest, and numerous national parklands. These areas attract millions of tourists to the state each year.

Arizona has the third-largest Indian population in the United States. Only Oklahoma and California have more Indians. Indian reservations cover more than a fourth of Arizona's land. About 256,000 Indians live in Arizona.

The contributors of this article are Lay James Gibson, Professor of Geography and Regional Development and Director of the Economic Development Research Program at the University of Arizona, and Thomas E. Sheridan, Curator of Ethnohistory at the Arizona State Museum.

Interesting facts about Arizona

The planet Pluto was discovered from the Lowell Observatory in Flagstaff. There, Clyde W. Tombaugh discovered Pluto in 1930.

Tucson is known as the *Astronomy Capital of the World.* No other place has as many telescopes concentrated in one area. About 30 are placed on mountain peaks near the city. Most are operated by three major observatories. Kitt Peak has the McMath telescope, the largest solar telescope in the world. It produces an image of the sun that has a diameter of about 30 inches (75 centimeters).

WORLD BOOK illustration by Kevin Chadwick

Astronomy Capital of the World

Casa Grande, an ancient "skyscraper" dating from about A.D. 1350, represents an engineering achievement in adobe construction. The four-story tower, in Coolidge, contains an 11-room house. It is 38 feet (11.6 meters) high. The Hohokam Indians built the structure by gradually tapering it toward the top.

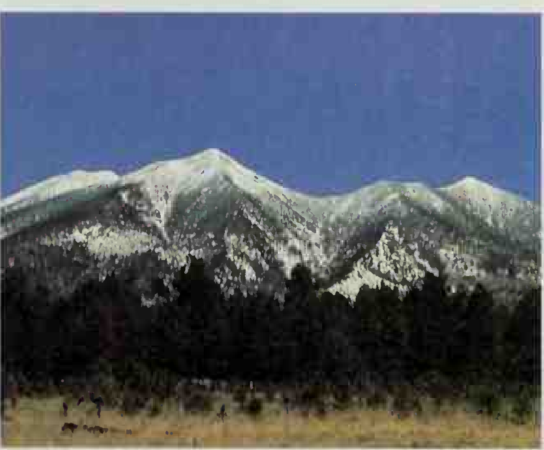
WORLD BOOK illustration by Stephen Brayfield

Casa Grande

Four states meet at Four Corners, the junction of Arizona, New Mexico, Colorado, and Utah. Highway U.S. 160 in Arizona leads directly to the site, which is marked by a low concrete monument that bears the seals of the four states.

The first organized rodeo to charge admission and award prizes was held at Prescott on July 4, 1888. Called a "Cowboy Tournament" at that time, the competition marked the beginning of the modern rodeo as an organized spectator sport. The Prescott Rodeo has been held each year since then.

Tom Campbell, West Light



Phoenix is the capital and largest city of Arizona. It lies in a desert valley surrounded by mountains. A corridor of high-rise buildings, *shown here,* extends along Central Avenue in the city's business district.

About three-fifths of them live on 21 reservations in the state.

Indians have contributed much to Arizona's history. Some Indians still live in communities built more than 800 years ago. Hundreds of years before Europeans arrived on the continent, Hohokam Indians in what is now central Arizona built the largest irrigation system in North America. After Europeans arrived in Arizona, the Indians fought to keep their rugged, beautiful land. Cochise and Geronimo, leaders of the Chiricahua Apache Indians, led war parties in Arizona long after most other Indians had surrendered.

Arizona's history also includes many years of rule by Spanish conquerors, and by Mexicans who freed the region from Spanish control. Today, a large number of Americans of Mexican ancestry live in Arizona. Their influence is apparent in the customs, foods, and place names found in the state.

Arizona derives its nickname, the *Grand Canyon State,* from its most famous physical feature. Phoenix is the state's capital and largest city.

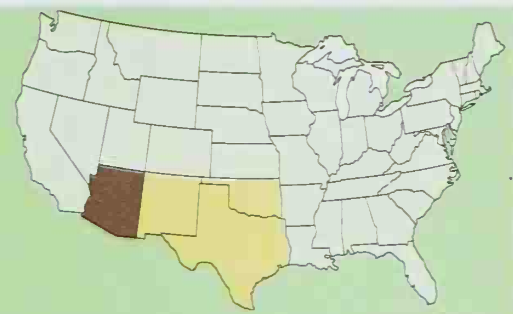
John Running, Hillstrom Stock Photos

The snow-covered San Francisco mountains rise near Flagstaff. Arizona's landscape provides vivid contrasts of rugged mountains, barren deserts, broad valleys, and deep canyons.

Arizona in brief

Symbols of Arizona

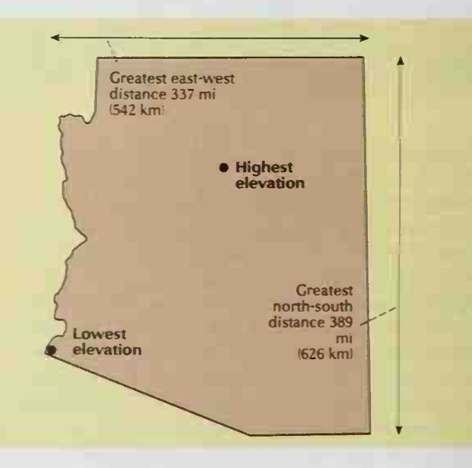
On the state flag, adopted in 1917, red and yellow rays represent the setting sun. These are the colors of Spain, carried by Coronado's expedition into the region in 1540. A copper-colored star represents the state's chief mineral product. The state seal, adopted in 1911, has symbols relating to important economic activities, including mining, cattle-raising, and farming. A dam and reservoir in the background show the importance of water resources.



State flag

State seal

Arizona (brown) ranks sixth in size among all the states and third in size among the Southwestern States (yellow).



The State Capitol is in Phoenix, the capital of Arizona since 1889. Earlier capitals were Fort Whipple (1864), Prescott (1864-1867 and 1877-1889), and Tucson (1867-1877).

General information

Statehood: Feb. 14, 1912, the 48th state.
State abbreviations: Ariz. (traditional), AZ (postal).
State motto: *Ditat Deus* (God Enriches).
State songs: "Arizona March Song." Words by Margaret Rowe Clifford; music by Maurice Blumenthal. "Arizona." Words and music by Rex Allen, Jr.

Land and climate

Area: 114,007 mi² (295,276 km²), including 364 mi² (943 km²) of inland water.
Elevation: *Highest*—Humphreys Peak, 12,633 ft (3,851 m) above sea level. *Lowest*—70 ft (21 m) above sea level along the Colorado River in Yuma County.
Record high temperature: 128 °F (53 °C) at Lake Havasu City on June 29, 1994.
Record low temperature: −40 °F (−40 °C) at Hawley Lake, near McNary, on Jan. 7, 1971.
Average July temperature: 80 °F (27 °C).
Average January temperature: 41 °F (5 °C).
Average yearly precipitation: 13 in (33 cm).

Important dates

1540 Coronado led a Spanish expedition into the Arizona region.

1776 Spaniards established a military outpost at Tucson.

1848 Mexico ceded most of present-day Arizona to the United States following the Mexican War.

Sources of information

For information about tourism, write to: Arizona Office of Tourism: 2702 N. 3rd Street, Suite 4015, Phoenix, AZ 85004. The Web site at www.arizonaguide.com also provides information.
For information on the economy, write to: Arizona Department of Commerce, 3800 N. Central Avenue, Suite 1500, Phoenix, AZ 85012.
The state's official Web site at www.state.az.us also provides a gateway to much information on Arizona's economy, government, and history.

1853 The United States and Mexico signed the Gadsden Purchase, which added more land to Arizona.
1912 Arizona became the 48th state on February 14.
1936 Hoover Dam was completed.
1974 Construction began on the Central Arizona Project, designed to provide water to needy areas of the state.
1981 Arizona judge Sandra Day O'Connor became the first woman appointed to serve on the U.S. Supreme Court.
1991 Central Arizona Project completed.

Population. The 2000 United States census reported that Arizona had 5,130,632 people. The population had increased 40 percent over the 1990 figure, 3,665,228. According to the 2000 census, Arizona ranks 20th in population among the 50 states.

About 88 percent of Arizona's people live in metropolitan areas. Over 60 percent live in the Phoenix-Mesa metropolitan area. Another sixth of the population lives in the Tucson metropolitan area (see Metropolitan area). For the populations of the state's metropolitan areas, see the *Index* to the political map of Arizona.

Phoenix, the largest city in Arizona, is a trading and shipping center for a rich agricultural district. Tucson is the second-largest city in the state. Both of these cities are important manufacturing centers and vacation areas. Arizona's other large cities include Mesa, Glendale, Scottsdale, Chandler, and Tempe.

About 5 out of 100 Arizonans are American Indians. Arizona has the third-largest Indian population in the nation. Only Oklahoma and California have more Indians. The Navajo are the largest tribe in Arizona. The Indian settlement of Oraibi, in northern Arizona, is one of the oldest continuously inhabited places in the United States. Hopi Indians built the settlement in the 1100's. Arizona has 16 tribal councils. These councils help govern the various tribes and supervise their property.

About 25 percent of Arizona's people are Hispanics. People of Mexican ancestry account for 82 percent of the state's Hispanic population. Many families in these groups speak Spanish at home, but the children in the families learn English at school. Mexican foods and customs are very popular among Arizonans. The state also has many people of German, English, and Irish descent.

Schools. The first schools in Arizona were established in the 1700's by Spanish missionary priests. These schools taught little except religion. In the late 1820's, the Mexican government expelled Spanish-born priests. By the 1840's, missions were abandoned. The first public school in Arizona opened in Tucson in 1871.

The state's school system is headed by an elected superintendent of public instruction. This official is a member of and carries out policy made by the State Board of Education. Other members of the board are appointed by the governor. They include a classroom teacher, a president of a state university, a representative of the state community colleges, a county school superintendent, a high school district superintendent, and three private citizens. Schools are financed chiefly by taxes.

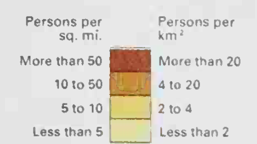
Children are required to attend school from the ages of 6 through 15. For the number of students and teachers in Arizona, see Education (table).

Navajo Community College in Tsaile, Arizona, was the first U.S. college located on an Indian reservation. It opened in 1969.

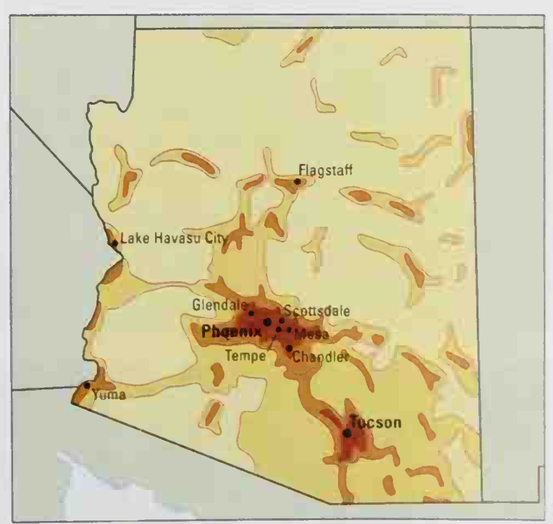
Libraries and museums. Mission libraries were the first libraries in Arizona. In the 1860's, Samuel Colt, the famous pistol maker, had a mine located in Arivaca, and he provided books for his workers. Tucson had a rental library in the 1870's. By 1878, both Phoenix and Prescott had small libraries. The Arizona Territorial Library, founded in 1864, became the Department of Library, Archives, and Public Records.

Arizona museums feature art, science, history, and American Indian cultures. The Arizona State Museum at the University of Arizona in Tucson and the Arizona Historical Society's Tucson museum are among the oldest in the state. The Arizona-Sonora Desert Museum, the International Wildlife Museum, and the Pima Air and Space Museum are near Tucson. The Museum of Northern Arizona, near Flagstaff, has exhibits of American Indian arts and crafts. Museums in the Phoenix area include the Phoenix Art Museum; the Heard Museum, which features American Indian art; Pueblo Grande Museum, with the remains of a prehistoric Indian village; the Arizona State Capitol Museum, with exhibits on the history of state government; and the Champlin Fighter Museum, which has fighter aircraft from many wars.

Universities and colleges



This table lists the universities and colleges in Arizona that grant bachelor's or advanced degrees and are accredited by the North Central Association of Colleges and Schools.



Name	Mailing address
American Indian College of the Assemblies of God	Phoenix
Argosy University	Phoenix
Arizona, University of	Tucson
Arizona State University	*
DeVry Institute of Technology	Phoenix
Embry-Riddle Aeronautical University	Prescott

Visitor's guide

Arizona attracts visitors throughout the year. But its winter season has become nationally famous. Thousands of vacationers flock to the sunny desert playgrounds when other parts of the country are cold. At the same time, ski resorts in the mountains of northern Arizona lure winter sports lovers. Dude ranches, historic sites, and magnificent scenery draw other travelers to the state. The outstanding scenic feature is the world-famous Grand Canyon, one of the seven natural wonders of the world. This giant gorge, 277 miles (446 kilometers) long and 1 mile (1.6 kilometers) deep, cuts through the rock of northwestern Arizona. Every year, millions of visitors gaze at its splendor. The Petrified Forest in northeastern Arizona is made up of ancient logs that were buried in mud, sand, or volcanic ash years ago and have turned to stone. Grand Canyon National Park and Petrified Forest National Park are among Arizona's many national parklands.

Arizona's popular annual events include rodeos, county fairs, and Indian ceremonials. These events are held throughout the year. On May 5, Arizona communities celebrate *Cinco de Mayo.* This Mexican holiday honors the victory of a Mexican army over an invading French force at Puebla, Mexico, in 1862.

Places to visit

Following are brief descriptions of some of Arizona's many interesting places to visit.

Apache Trail, a scenic mountain highway, passes Indian ruins in the rugged Tonto National Forest.

Arizona-Sonora Desert Museum, west of Tucson, features exhibits on desert animals and plants.

Canyon de Chelly National Monument, in Chinle, features colorful, steep-walled canyons that house the ancient ruins of Indian villages, including White House and Standing Rock.

Kitt Peak National Observatory, southwest of Tucson on the Tohono O'odham Indian reservation, has telescopes mounted on the 6,875-foot (2,096-meter) peak.

London Bridge, at Lake Havasu City, is a stone bridge first built in London in the early 1800's. The bridge opened at Lake Havasu City in 1971 after its stones were disassembled, shipped to the United States, and reassembled in their original form.

Meteor Crater, in Coconino County, is a large hole that measures 4,180 feet (1,275 meters) wide and 570 feet (175 meters) deep. The crater was created when a huge object from space struck the earth. Fragments of meteorite material have been found nearby. See Meteor (picture).

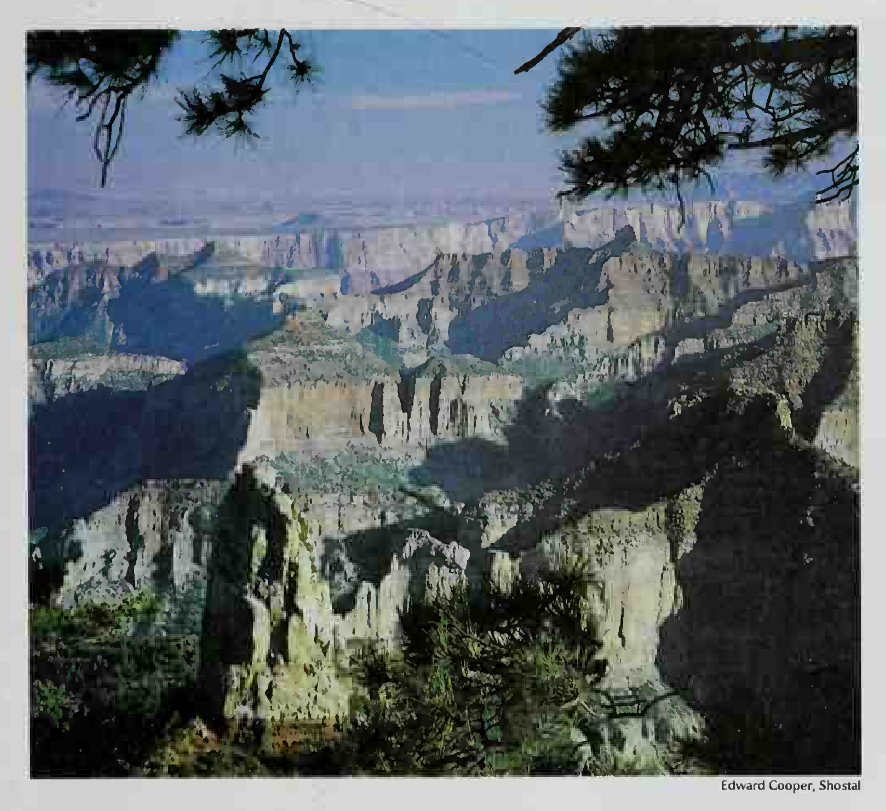
Monument Valley Navajo Tribal Park is on the Navajo reservation in northeastern Arizona. The tribal council has a tourist center there.

Oak Creek Canyon, near Sedona, has red-rock formations that some people consider second in beauty and coloring only to those of the Grand Canyon.

Painted Desert, with colorful rock and sand, extends about 200 miles (320 kilometers) along the Little Colorado River in northern Arizona.

San Xavier del Bac Mission, near Tucson, is the best preserved of Arizona's early missions. It features numerous beautiful and unusual carvings and paintings.

Tombstone, a famous Western boom town, is in Cochise County. Many tourists visit the area, where Wyatt Earp won fame as a gunfighter.



National parklands are among Arizona's chief attractions. Grand Canyon National Park is a famous scenic wonder. The state's other national parks are Petrified Forest, site of the world's greatest concentration of petrified wood, and Saguaro, noted for giant cactuses. Arizona has seven national forests. Coconino, Kaibab, Prescott, Sitgreaves, and Tonto lie completely in Arizona. Apache and Coronado lie partly in New Mexico. Six national forest areas are national wildernesses. Arizona's 13 national monuments are Canyon de Chelly, Casa Grande Ruins, Chiricahua, Hohokam Pima, Montezuma Castle, Navajo, Organ Pipe Cactus, Pipe Spring, Sunset Crater Volcano, Tonto, Tuzigoot, Walnut Canyon, and Wupatki. Other parklands in the state include Coronado National Memorial, Fort Bowie National Historic Site, Hubbell Trading Post National Historic Site, and Tumacácori National Historical Park. Glen Canyon National Recreation Area lies partly in Arizona and partly in Utah. Lake Mead National Recreation Area is partly in Arizona and partly in Nevada.

State parks. Arizona has a number of state parks. For information, write State Parks Director, Arizona State Parks, 1300 W. Washington Street, Suite 415, Phoenix, AZ 85007.

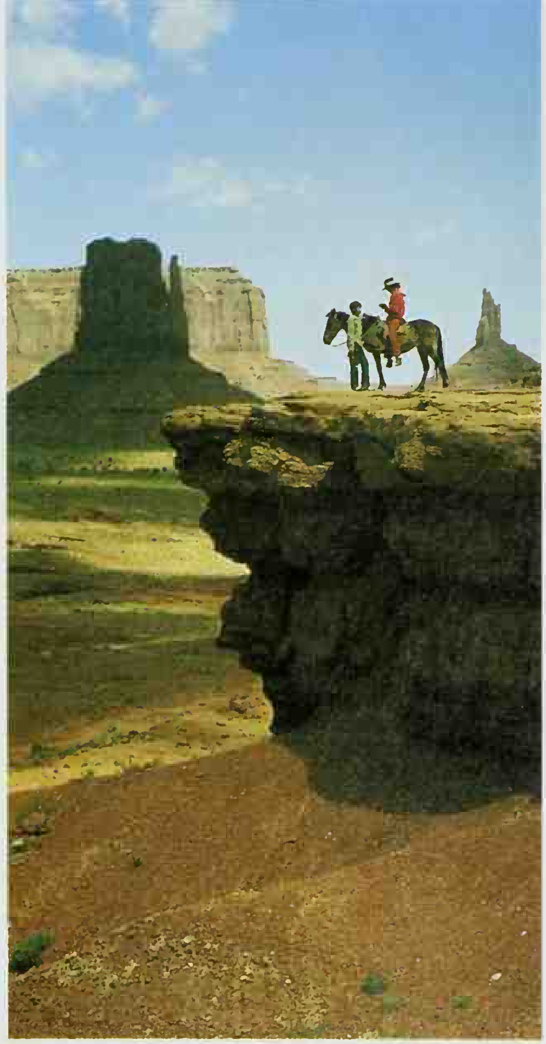
Annual events

January-April

Arizona National Livestock Show in Phoenix (January); La Fiesta de los Vaqueros rodeo in Tucson (third week in February); Easter Sunrise Service at the Shrine of the Ages on the South Rim of the Grand Canyon (Easter Sunday).



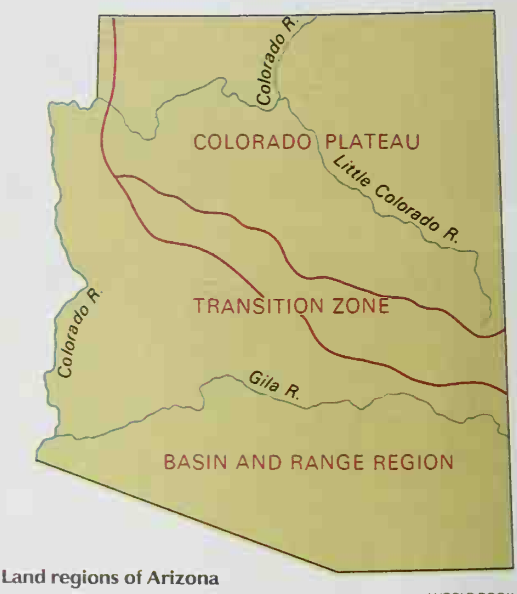
May-August

Festival of Hispanic Arts and Crafts in Flagstaff (May); Wyatt Earp Days in Tombstone (May); Arizona's Own Garlic Festival in Dewey (June); Frontier Days in Prescott (first week in July); Festival in the Pines in Flagstaff (August).

September-December

Navajo Tribal Fair in Window Rock (September); London Bridge Days at Lake Havasu City (mid-October); Annual Thunderbird Invitational Hot-Air Balloon Races in Scottsdale (early November); Fiesta Bowl Sports Festival in Phoenix, Scottsdale, and Tempe (December-January).

Land and climate



David A. Barnes, Stock Market

Monument Valley in Arizona's Colorado Plateau has beautiful rock formations. The Colorado Plateau, in northern Arizona, also includes the Grand Canyon and the Painted Desert.

Land regions. Arizona has three main land regions: (1) the Colorado Plateau, (2) the Transition Zone, and (3) the Basin and Range Region.

The Colorado Plateau, in northern Arizona, covers about two-fifths of the state. The region consists of a series of plateaus with fairly level surfaces. This pattern is broken here and there by a few mountains and canyons. Humphreys Peak, the highest mountain in the state, rises 12,633 feet (3,851 meters) near Flagstaff. The deepest canyon is the famous Grand Canyon on the Colorado River. Tributaries of the Colorado have cut other beautiful canyons into the flatland. These include Canyon de Chelly and Oak Creek Canyon.

Many of the mountains are forested, but the region also has dry deserts with little vegetation. Along the Arizona-Utah border in the northeast, strange and beautiful rock formations rise from the floor of a broad valley. They gave the valley the name Monument Valley. The colorful Painted Desert and the Petrified Forest are two well-known parts of the region. The series of level plateaus that makes up the region ends in the Mogollon

Rim on the south. The Mogollon Rim is a steep rock wall almost 2,000 feet (610 meters) high. It extends from central Arizona to the Mogollon Mountains in southwestern New Mexico. The principal industries of Arizona's Colorado Plateau are livestock raising, lumbering, and tourism.

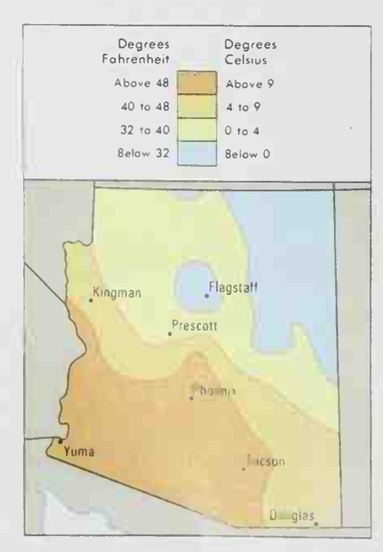
The Transition Zone is a narrow strip of land that lies just south of the Colorado Plateau. This region has a number of mountain ranges. The ranges are close together in an area of rugged peaks and narrow valleys. This rough country in Arizona includes the Mazatzal, Santa Maria, Sierra Ancha, and White mountain ranges.

The Basin and Range Region includes most of the southern part of the state and a narrow strip in the west. Mountain ranges run through the Basin and Range Region from northwest to southeast. The most important mountain ranges are the Chiricahua, Gila, Huachuca, Hualapai, Pinaleño, Santa Catalina, Santa Rita, and Superstition ranges. The mountain valleys are broad and fertile. This part of the Basin and Range Region produces excellent crops when the soil is irrigated. The state's largest cities developed in this area.

In the extreme west and south of the Basin and Range Region, the mountains are low and barren. Broad desert basins lie between the ranges. This area of the state gets little rain, and it has almost no vegetation. Along the western border of Arizona, water from the Colorado River is used to irrigate the dry land. The irrigated land produces excellent crops.

Rivers, waterfalls, and lakes. Arizona's most important river is the Colorado. In Arizona, the river is 688 miles (1,107 kilometers) long. It enters the state from Utah almost in the middle of the northern border. Then it winds west through the Grand Canyon and turns south. The river forms almost the entire western boundary of Arizona.

The Colorado and its tributaries drain most of the state. Before 1935, the muddy Colorado carried about a million tons of rich soil to the Gulf of California every day. Irrigation and power dams on the great river and its branches have helped control the flow, and the river is much clearer today.



Few small streams in Arizona flow all year. Some mountain creeks have a steady flow, but most streams often seem dry. Rushing water fills the riverbeds of the Bill Williams, Little Colorado, San Pedro, and Santa Cruz rivers after a rain. At other times, these rivers appear to be dry. However, water always flows beneath their sandy beds. Many mountain streams tumble down cliffs and canyon walls in waterfalls and cascades. The best-known falls include Beaver, Bridal Veil, Havasu, Mooney, and Navajo. All of these falls are on Havasu Creek in the Supai Canyon area of the Grand Canyon.

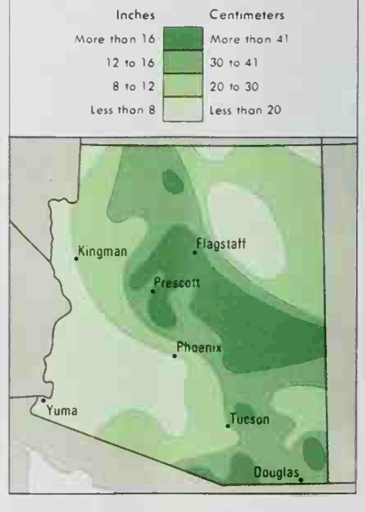
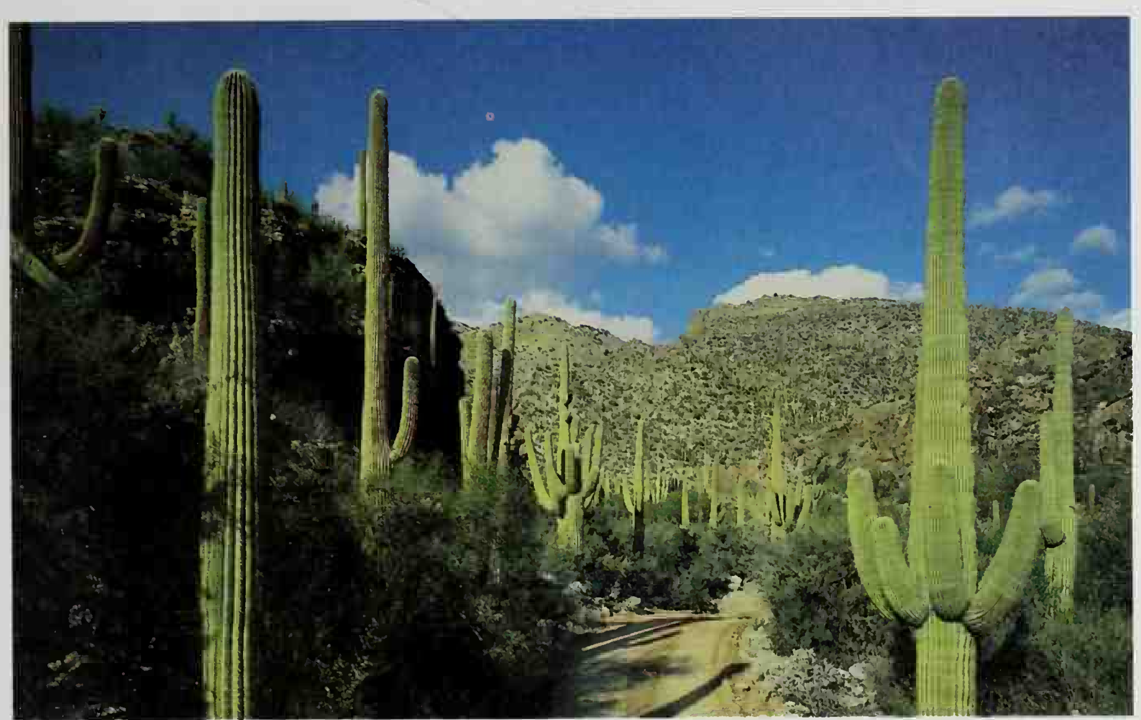
Average January temperatures

In winter, southern Arizona has a mild climate. Mountain areas of central and northern Arizona are much colder.

Average July temperatures



In summer, Arizona's southern deserts have extremely hot, dry weather. Higher elevations are considerably cooler.



Average yearly precipitation

Little rain falls in desert areas. The mountains receive much heavier rainfall. Snow is abundant in some mountain areas.

WORLD BOOK maps

Manley Features from Shostal

Saguaro National Park in southern Arizona's Basin and Range Region is named for its giant saguaro cactuses. Many kinds of cactuses thrive in the broad desert areas of the region.

Several small natural lakes lie in the mountain areas of the state, but all the largest lakes are artificially created. Many artificial lakes have been made by damming streams for irrigation and for water conservation. The largest of these lakes include Theodore Roosevelt Lake and San Carlos Lake. Lake Mead, behind Hoover Dam, lies partly in Nevada. Part of Lake Havasu, formed by Parker Dam, is in California. Lake Powell, which was created by Glen Canyon Dam, lies partly in Arizona and partly in Utah.

Plant and animal life. Forests cover more than a fourth of Arizona's land. The mountain regions of the state have the largest area of ponderosa pine in the United States. Other trees in the state include aspen, blue spruce, cottonwood, Douglas-fir, juniper, piñon, walnut, and white fir.

Arizona is famous for its cactus plants. The sharp-spined cholla cactus is common in the hot desert areas. Creosote bushes and prickly pear cactuses also grow in the desert. The organ-pipe cactus is found in desert areas near sea level. The saguaro, which is common in southern Arizona, grows larger than any other cactus in the United States. The saguaro blossom is the state flower.

Other unusual plants that grow in Arizona include the night-blooming cereus and several varieties of the yucca plant. Arizona wildflowers include the geranium, golden columbine, paintbrush, phlox, pink, poppy, and sand verbena.

Animal life in Arizona includes large numbers of mule deer and white-tailed deer. Other big-game animals include black bears, elk, bighorn sheep, and pronghorns. Several members of the cat family, including bobcats and mountain lions, prowl in the forested areas. Jaguars are occasionally sighted in southern Arizona.

Other Arizona animals include badgers, beavers, foxes, raccoons, skunks, squirrels, and weasels. The state is also home to the *collared peccary* or *javelina,* an animal distantly related to the wild hog.

Arizona has over 40 kinds of lizards, including the poisonous Gila monster. Rattlesnakes live in most parts of the state, and the rare, poisonous coral snake is found in the desert. The state's hotter areas have scorpions and tarantulas.

Arizona's game birds include doves, grouse, quail, wild turkeys, and various waterfowl. Trout swim in the Colorado River and in the mountain streams. Other fishes include bass, bluegills, and crappies.

Climate. Temperatures vary greatly in Arizona. Mountain areas often have winter temperatures below 0 °F (−18 °C). The southern deserts may not have freezing weather for years. The dry air in the deserts makes cold or heat seem more comfortable there than in humid regions.

The state's highest temperature, 128 °F (53 °C), was recorded at Lake Havasu City on June 29, 1994. Hawley Lake, near McNary, had the record low, −40 °F (−40 °C), on Jan. 7, 1971. In Phoenix, temperatures average about 91 °F (33 °C) in July, and about 51 °F (11 °C) in January.

Precipitation varies greatly throughout the state. The deserts of the southwest get only 2 to 5 inches (5 to 13 centimeters) of moisture a year. Arizona's high mountain areas may receive as much as 30 inches (76 centimeters) a year.

Economy

Service industries provide the vast majority of jobs for residents of this rapidly growing state. Arizona's service industries include such activities as education, health care, real estate, and retail trade. Many service industries benefit from spending by tourists and by retired people who live in the state all or part of the year.

Manufacturing in Arizona is based on high-technology products, such as computers, electronic equipment, and aerospace vehicles. Agriculture and mining are also important in Arizona. The state has many cattle ranches and is the nation's leading copper producer.

Natural resources. Arizona's leading natural resources are its warm climate and its mineral deposits.

Water is a scarce resource in Arizona. Expanding urban areas require more water. Farmers must bring water to their land to make crops grow. A system of canals supplies the water. The canals follow ancient canals built by the Hohokam Indians hundreds of years before Europeans came to the area. The water comes from mountain reservoirs fed by winter snow and spring rain. But Arizona uses more water than it can get from its streams and storage reservoirs. The state's underground water supply is being used up faster than nature can replace it.

In 1968, the United States Congress approved funding for the Central Arizona Project, a system of canals, tunnels, and pipelines. The system, completed in 1991, provides for pumping large quantities of water from the Colorado River to the Phoenix and Tucson areas for agricultural and other purposes. Arizona has also put in place a statewide water management and water reclamation program to meet current water needs while replenishing the state's supply of underground water.

Minerals. Arizona's mountains and plains contain large deposits of minerals and other materials, the most valuable of which is copper. Sand and gravel come from all 15 counties in the state. Other mined products in Arizona include coal, gold, petroleum, pumice, silver, stone, and uranium. Molybdenum and vanadium, which are used in hardening steel, are also present. Arizona's less important mined resources include clay, bentonite, feldspar, gypsum, lead, natural gas, quartz, and salt.

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Community, business, & personal services	21	846,300	32
Finance, insurance, & real estate	19	238,700	9
Wholesale & retail trade	17	579,400	22
Manufacturing	15	227,100	9
Government	12	343,300	13
Transportation, communication, & utilities	7	115,500	4
Construction	6	179,700	7
Agriculture	2	68,300	3
Mining	1	15,700	1
Total	100	2,614,000	100

*GSP = gross state product, the total value of goods and services produced in a year.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

Soil. Only about an eighth of Arizona's soil is suitable for farming because of the limited amount of water available for irrigation. Soils of the plateau region in northern and eastern Arizona are thin and gray. The mountain soils also are thin and are brown or gray. The lowlands of southwestern Arizona have red soils. In some parts of this region, the soil lies over another layer of soil called *caliche.* This concretelike soil may be so hard that power tools may be needed to dig holes.

Service industries in Arizona account for the largest portion of the *gross state product*—the total value of goods and services produced in a state in a year. Most of the service industries in the state are concentrated in the Phoenix and Tucson areas.

Community, business, and personal services contribute more to the gross state product and employ more people than any other economic activity in Arizona. This industry group consists of a variety of businesses, including private health care, hotels and resorts, law firms, and repair shops. Arizona's hotels and resorts receive much business from tourists during the winter.

Finance, insurance, and real estate ranks second among Arizona's service industries in terms of contributions to the gross state product. Real estate is the most important part of this industry group. The state's rapidly growing population has created a strong demand for new housing. A large number of office buildings and resorts are being developed. Phoenix is Arizona's major financial center. Several large banks are based in the city.

Wholesale and retail trade ranks third among Arizona's service industries. The wholesale trade of farm products, mined products, and motor vehicles is important in the state. Major types of retail businesses include automobile dealerships, department stores, and food stores. Circle K, a large chain of convenience stores that also provides gasoline service, has its corporate headquarters in Phoenix.

Government ranks next among Arizona's service industries. Government services include the operation of public schools and hospitals, military establishments, and Indian reservations. Arizona State University in Tempe and Phoenix and the University of Arizona in Tucson, two of the nation's largest universities, are among the state's leading employers. Military bases in Arizona include Davis-Monthan Air Force Base, Fort Huachuca Military Reservation, Luke Air Force Base, and the Yuma Proving Ground. The state has several large Indian reservations. The Navajo reservation, the nation's largest reservation, covers most of northeastern Arizona.

Transportation, communication, and utilities ranks fifth among Arizona's service industries. America West Airlines, a major U.S. transportation company, is based in Phoenix. Phoenix is also the home of Pinnacle West, a major electric power company. Telephone companies are the most important part of the communications sector. More information about transportation and communication appears later in this section.

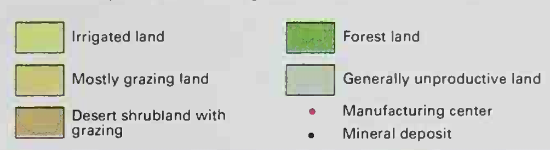
Manufacturing. Products made in Arizona have a *value added by manufacture* of about $28 billion a year. This figure represents the increase in value of raw materials after they become finished products.

Arizona's leading manufactured products, in terms of value added by manufacture, are computer and elec-

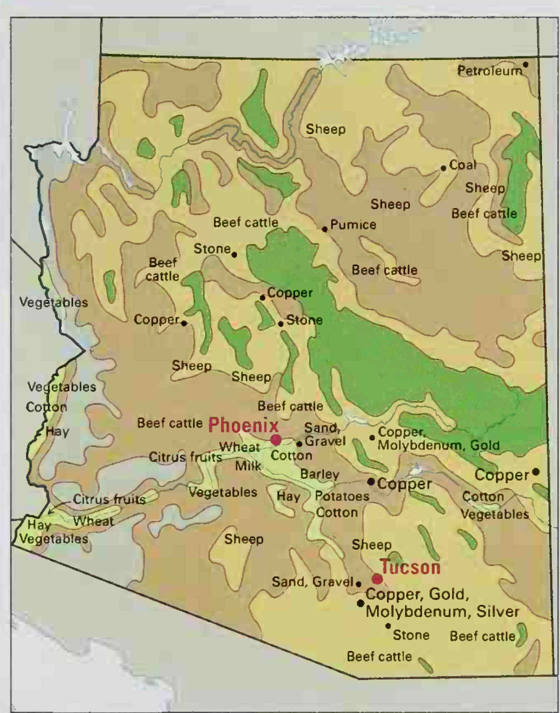
tronic equipment, transportation equipment, and chemicals. Factories in Phoenix or nearby cities produce most of the state's electronic equipment. Plants in Chandler, Mesa, Phoenix, and Tempe make computer microchips and other electronic components. Electronic communication systems are manufactured in Scottsdale.

Both the Phoenix and Tucson areas turn out large amounts of transportation equipment. A factory just outside Phoenix makes space vehicles. Helicopters are produced in Mesa. Turbine engines are produced in Phoenix. Plants in Phoenix and Tempe make aircraft parts. Guided missiles are produced in Tucson.

Other types of manufactured products made in Arizona include fabricated metal products, food products, machinery, and primary metals. Important fabricated metal products include structural metals, including sheet metal and frames for windows and doors. Food products include soft drinks, baked goods, animal feed, and dairy products. Arizona's factories turn out machinery for use in the metalworking, electronics, and agriculture industries. Copper is, by far, the leading type of primary metal produced in the state.



Agriculture. Arizona has about 7,400 ranches and farms. Grazing land covers about three-fourths of the state. Less than 5 percent of Arizona's land is used for growing crops. Yet nearly two-thirds of the state's total farm income comes from crops. All of Arizona's 15 counties have some irrigated land. Maricopa, Pinal, and Yuma counties have the most productive irrigated areas in the state.



Crops account for about 65 percent of Arizona's total farm income. Lettuce is the most valuable crop. Iceberg, leaf, and romaine lettuce are grown by Arizona's farmers. Cotton is the second most valuable crop, and Arizona ranks among the leading cotton-producing states. Cotton production is concentrated in south-central Arizona, between Phoenix and Tucson. Arizona is also among the leading producers of citrus fruits and melons. Other important crops include barley, hay, potatoes, and wheat.

Livestock accounts for about 35 percent of Arizona's farm income. Beef cattle are the single leading source of farm income in the state. The primary region for raising

Economy of Arizona

This map shows the economic uses of land in Arizona and where the state's leading farm and mineral products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

beef cattle lies just south of the central mountains. The northeastern part of the state and the valleys in the mountain region also have many cattle ranches. Northeast Arizona also has many sheep pastures. Most of the state's dairy farms lie southwest of Phoenix.

Mining. Copper provides most of Arizona's mining income. Greenlee, Pima, and Pinal counties in the southern part of the state supply most of the copper. Gila and Yavapai counties also have major copper mines. Large amounts of gold, molybdenum, and silver are recovered as by-products of mining copper ore. Phelps Dodge, a major mining company, is headquartered in Phoenix.

Coal, sand and gravel, and crushed stone are also important mined products in Arizona. Coal is obtained from surface mines in Navajo County. Maricopa and Pima counties produce the most sand and gravel. Pima and Yavapai counties have large stone quarries.

Electric power. Power plants that burn coal supply about 45 percent of the electric power generated in Arizona. Nuclear plants generate about 35 percent of the state's power. Hydroelectric plants produce most of the rest of the remaining power.

Transportation. Arizona has about 56,000 miles (90,000 kilometers) of roads and highways. Interstate 10

An electronics plant in Chandler is one of Arizona's many high-technology industries. The operators above are being trained to inspect semiconductors.

Glen Canyon Dam, on the Colorado River in northern Arizona, was completed in 1964. It helps regulate the river flow, and its huge generators produce hydroelectric power.

Manley Features from Shostal

connects Tucson, Phoenix, and Los Angeles. The part of Arizona north of the Colorado River is isolated from the rest of the state by the Grand Canyon. No roads cross the canyon.

Sky Harbor International Airport in Phoenix is the state's busiest commercial airport. Tucson has the state's second busiest airport. In 1919, Tucson became the first U.S. city to have its own municipal airport.

Several railroads provide freight service, and passenger trains serve several cities in the state. The Southern Pacific (now part of the Union Pacific) became the first railroad to enter the region, reaching Yuma in 1877.

Communication. Arizona's first newspaper, the *Weekly Arizonian,* began publication in Tubac in 1859. Today, about 95 newspapers, including about 20 dailies, are published in the state. Arizona's leading papers include *The Arizona Republic* of Phoenix, *The Arizona Daily Star* of Tucson, and *The Tribune* of Mesa. Arizona's publishers also print about 110 magazines.

The state has about 120 radio stations and 25 television stations. KTAR, then called KFAD, was Arizona's first commercial radio station. It began broadcasting in Phoenix in 1922. The state's first television station, KPHO-TV, began broadcasting from Phoenix in 1949. Today, cable television systems and Internet providers serve many Arizona communities.

Government

Constitution. Arizona is governed under its original Constitution, which was adopted in 1911. The Constitution has been *amended* (changed) about 120 times.

All amendments must be approved by a majority of the voters in an election. Amendments may be proposed by a majority of both houses of the state Legislature, by petition from the voters, or by a constitutional convention. A convention may be called if approved by a majority vote of both houses, and then by a majority of the people voting on the question in an election.

Executive. The governor of Arizona is elected to a four-year term. The governor may serve any number of terms, but no more than two terms in a row.

Arizona has no lieutenant governor. A governor who dies or resigns is succeeded by one of the other four state officials elected by the voters. These are, in order of succession, the secretary of state, attorney general, state treasurer, and superintendent of public instruction. All serve four-year terms. They may serve any number of terms, but no more than two in a row.

Legislature consists of a 30-member Senate and a 60-member House of Representatives. Each of Arizona's 30 legislative districts elects one senator and two representatives to two-year terms. These officials may serve any number of terms, but no more than four in a row. The Legislature meets each year on the second Monday in January. Rules have been adopted to end the sessions no later than the Saturday after the 100th day. But the president of the Senate and the speaker of the House of Representatives may extend a session for no longer than seven days. After that, the session can be extended only by a majority vote of the Legislature. The governor may call a special session, which has no time limit.

Courts. The highest court in Arizona is the state Supreme Court. Its five justices are appointed to six-year terms by the governor from a list of candidates submitted by a Commission on Appellate Court Appointments. At the end of each justice's term, the judge runs unopposed as a nonpartisan candidate and the voters decide if the judge should be retained. The justices elect one of their members as chief justice for a five-year term.

A state Court of Appeals was created in 1965. This court has two divisions, one centered in Phoenix and the other in Tucson. The Phoenix division has 15 judges, and the Tucson division has 6 judges. These judges serve six-year terms and are selected and retained in the same way as are Arizona Supreme Court justices. Superior Courts in each county handle most major criminal and

civil cases. Superior Court judges in Maricopa and Pima counties are appointed by the governor to four-year terms. In other counties, Superior Court judges are elected to four-year terms. After that, voters decide whether they are retained. Justice-of-the-peace courts and municipal courts deal with less important cases.

Local government in Arizona is carried on through 15 counties and over 80 incorporated cities and towns. Counties are governed by a three- or five-member board of supervisors. Supervisors are elected to four-year terms. Counties have either a county-manager or an administrator who conducts the daily business of the county and is guided by the board of supervisors.

Communities with over 1,500 people may vote to incorporate their community as a city or town. Towns in Arizona are governed by councils of five or seven members, depending on the size of the community. The council elects one of its members as mayor. Some Arizona cities also use this same system. However, a city may adopt a *home rule* charter, which allows it to change the form of its government. More than 60 cities, including most of the largest ones, have city managers.

Revenue. Taxes provide about 60 percent of the state government's *general revenue* (income). Four taxes produce almost all the tax money. These are (1) a sales tax, (2) income taxes on corporations and individuals, (3) a tax on motor fuels, and (4) property taxes. Federal grants and U.S. and local government programs provide about a fourth of the general revenue. Most of the rest of the government's revenue comes from taxes on licenses.

Politics. For many years, Democrats controlled Arizona politics, particularly on the local level. Since 1950,

The Arizona House of Representatives meets in Phoenix, the state capital. Arizona's legislature consists of a 60-member House of Representatives and a 30-member Senate. Both senators and representatives are elected by Arizona's voters to serve two-year terms.

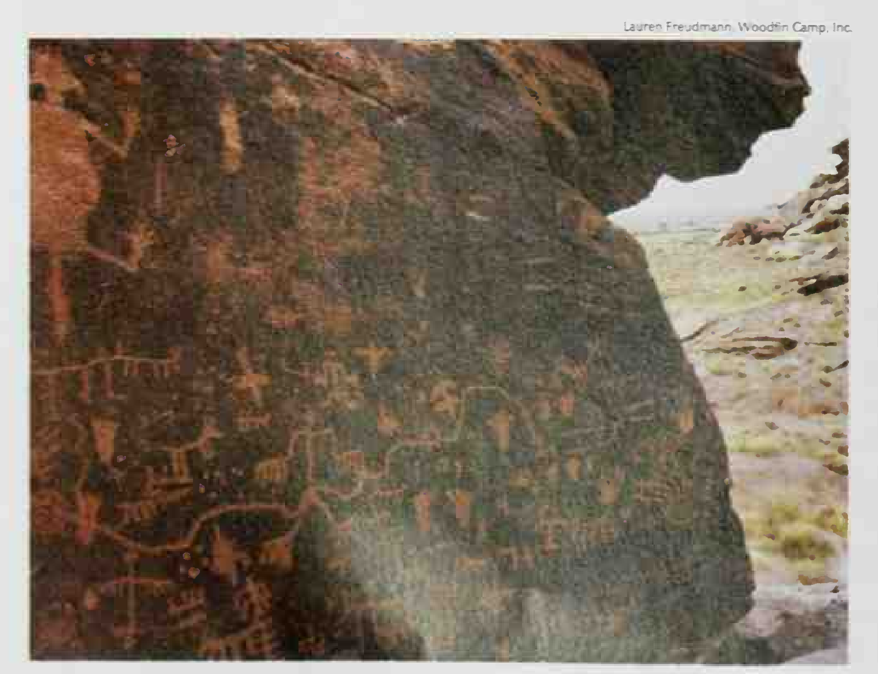
however, Republicans have won the support of many voters in Arizona's rapidly growing cities. The state's largest city, Phoenix, usually produces a Republican majority. Democratic strength is greater in rural areas and small towns.

Maricopa County, in which Phoenix is located, has a majority of the state's voters. As a result, that county is extremely important in elections. Among the Republican leaders who helped make Arizona a two-party state was U.S. Senator Barry M. Goldwater, the Republican candidate for president in 1964.

In presidential elections, Arizona has voted for Republican candidates about two-thirds of the time, including most of the presidential elections since 1952. For Arizona's electoral votes and voting record in presidential elections, see **Electoral College** (table).

History

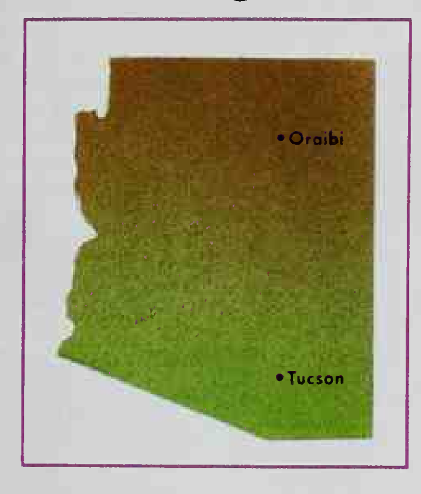
Early days. Indians have lived in Arizona for at least 12,000 years. Over the centuries, many of them built large settlements and developed civilizations known as the Anasazi, also called Ancestral Pueblo; Hohokam; and Mogollon. The Anasazi, who lived in the north, were the ancestors of the present-day Pueblo Indians. The Hohokam, who settled in the Gila and Salt river valleys, constructed the largest irrigation systems in North America before Europeans arrived. Their descendants are the Pima Indians and the Tohono O'odham, also known as the Papago Indians. The Mogollon lived in what are now eastern Arizona and western New Mexico. Apache and Navajo Indians moved into the Arizona area shortly before the Spaniards arrived.



Spanish exploration. During the 1530's, stories reached the Spaniards in Mexico telling about the great wealth of the Seven Cities of Cíbola. Spanish authorities sent a small group headed by Franciscan priest Marcos de Niza to find the cities. Niza, in 1539, became the first European known to enter the Arizona region. He reported seeing one of the seven cities from a distance. In 1540, a much larger expedition led by explorer Francisco Vásquez de Coronado traveled to Zuni pueblos and other Pueblo Indian settlements in what is now northern New Mexico. Lieutenants of Coronado visited Hopi pueblos and the Grand Canyon in what is now northern Arizona. The expedition found neither gold nor silver and returned to Mexico disappointed.

Spanish settlement of Arizona began in 1629, when Franciscan priests established missions among the Hopi. In 1680, however, the Hopi killed their missionaries and threw off Spanish rule. In the late 1600's and early 1700's, Jesuit missionary Eusebio Kino founded a number of missions among the O'odham Indians in what are now northern Mexico and southern Arizona.

Because Spanish and mission Indian settlements had cattle, horses, sheep, and goats, they became targets of raids by Apache Indians. The threat of Apache attacks limited permanent Spanish settlement to the Santa Cruz river valley. There, in 1752, Spanish troops established the state's first white settlement, a military post at Tubac. During 1775 and 1776, the soldiers moved to Tucson. They built a fort there with high, thick adobe walls to protect themselves and the settlers from Apache attacks.



Mexico won its independence from Spain in 1821, and the land that is now Arizona became part of the new country. In 1846, the United States went to war with Mexico. U.S. forces took control of the region. Under the terms of the Treaty of Guadalupe Hidalgo, which ended the war in 1848, the United States took possession of

Ancient rock carvings offer evidence of Arizona's early Indian inhabitants. The carvings shown here, on Newspaper Rock in Petrified Forest National Park, have never been translated.

Historic Arizona

Oraibi is one of the oldest continuously inhabited settlements in the United States. It was built by Hopi Indians during the 1100's.

Father Eusebio Kino, a Jesuit, did missionary work in southern Arizona and northern Sonora, Mexico, from 1687 until his death in 1711. He started many grain and stock farms.

Tucson, originally a walled city, was established by Spaniards in 1776 as a military outpost for defense against hostile Indians.

Geronimo, a leader of the Chiricahua Apache Indians, led attacks on soldiers and settlers in Arizona and New Mexico during the 1870's and 1880's. He finally surrendered to federal troops in 1886.

Hoover Dam, completed in 1936, provides water for generating power and irrigating land. The state's other large dams include Coolidge, Glen Canyon, Parker, and Roosevelt.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Arizona

1539	Marcos de Niza, a Franciscan priest, entered what is now Arizona.
1540	Francisco Coronado led a Spanish expedition into the region.
1776	Tucson was established as a military outpost.
1821	Arizona became part of Mexico.
1848	Following the Mexican War, Mexico ceded to the United States most of what is now Arizona.
1853	The United States and Mexico signed the Gadsden Purchase, which added territory to Arizona.
1863	Congress created the Arizona Territory.
1912	Arizona became the 48th state on February 14.
1936	Hoover Dam was completed.
1948	Arizona Indians received the right to vote.
1974	Construction began on the Central Arizona Project to provide water from the Colorado River to the state's needy areas. The project was completed in 1991.
1975	Raul H. Castro became the first Mexican American governor of Arizona.
1981	Arizona Judge Sandra Day O'Connor became the first woman appointed to the U.S. Supreme Court.
1988	Governor Evan Mecham was removed from office. He was replaced by Secretary of State Rose Mofford, the first woman to serve as Arizona's governor.
1997	Arizona Governor Fife Symington resigned.
1998	Jane Dee Hull, who had replaced Symington, was elected to a full term. She became the first woman to be elected governor of Arizona.

Arizona Historical Society Library

Tombstone, shown above in 1882, sprang up because of a silver-mining boom nearby. Gold and silver discoveries brought many people to the Arizona Territory. Lawlessness was widespread in Tombstone. The famous gunfight at the O.K. Corral took place there in 1881.

New Mexico. At that time, New Mexico included Arizona as far south as the Gila River. Many Easterners opposed the treaty because they feared that slavery would be established in the newly acquired land. But the U.S. Senate approved the treaty.

In 1853, the United States and Mexico signed the Gadsden Purchase. Through this treaty, the United States acquired the region south of the Gila River that forms the present boundary between the United States and Mexico.

Territorial days. The Civil War (1861-1865) brought great political changes to Arizona. In the 1850's, the settlers had asked Congress to create an Arizona Territory, but their requests were ignored. After the Confederacy was formed, many Arizona settlers wanted to join it because they had come from the South. They chose a delegate to the Confederate Congress.

In 1862, the Confederacy sent troops to occupy the New Mexico and Arizona areas. Union forces defeated the Southerners. In 1863, the Confederate government created the Confederate Territory of Arizona. The action had little meaning because of the earlier military defeat.

The Confederate activity led to action by the United States. Congress created the Arizona Territory with boundaries about the same as those of the present state. On Dec. 27, 1863, John N. Goodwin officially took control of the area as territorial governor. Goodwin established his headquarters at Fort Whipple. A log house was built for him not far from the fort. The town of Prescott grew up around this house.

Indian fighting. Arizona's few settlers lived in fear of hostile Indians. The Navajo were defeated in 1864 in a campaign led by the famous scout Kit Carson. But the Apache continued to fight. Small bands of warriors made hundreds of raids on lonely ranches and outposts throughout the Southwest. Under such leaders as Cochise, Geronimo, and Mangas Coloradas, the Apache even attacked forts and towns. The last raiding party under Geronimo finally surrendered on Sept. 4, 1886.

Territorial progress. In spite of almost constant Indian fighting, Arizona made great progress. Gold and silver discoveries brought many miners to the territory. As early as 1867, farmers in the Salt River Valley near present-day Phoenix began irrigating their fields. Ranching became a large-scale business during the 1880's. The rich copper mines of Arizona became highly developed in the 1880's and 1890's. The Southern Pacific Railroad entered Arizona from California on Sept. 30, 1877.

Statehood. Strong movements began about 1890 to make the territory a state. But Congress refused to act. In 1910, Congress permitted Arizona to draw up a constitution and apply for statehood. But again there was a delay. President William Howard Taft vetoed the bill because the proposed state constitution would have permitted the voters to remove judges from office by a process known as *recall* (see **Recall**). This clause was taken out of the Constitution, and statehood was approved. Arizona became the 48th state on Feb. 14, 1912. The people soon changed their Constitution to allow the recall of judges.

Progress as a state. George W. P. Hunt, a Democrat, greatly influenced Arizona's early history. He became the state's first governor and served seven terms. Hunt supported the development of dams and irrigation systems, and he worked for laws favorable to the ranching and mining industries.

Federal projects helped the new state in water development and tourism. The first big dam providing irriga-

tion water was the Theodore Roosevelt Dam, completed in 1911 on the Salt River above Phoenix. More dams were built during the next 25 years. Coolidge Dam on the Gila River, Bartlett Dam on the Verde River, and three more dams on the Salt River added greatly to the state's irrigated area. The biggest dam, Hoover Dam on the Colorado River, was completed in 1936. The U.S. government helped increase tourism by developing scenic and historic spots. The warm, dry climate attracted health seekers and winter visitors.

During World War I (1914-1918), cotton became an important crop. The amount of irrigated land expanded rapidly, and agricultural production increased. Farmers became reliant on water pumped from the ground. Arizona's copper production increased through the 1920's. The Great Depression of the 1930's forced workers in many parts of the nation to seek new jobs. Some of them settled in Arizona. Between 1920 and 1940, the population grew from 334,162 to 499,261.

The mid-1900's. During World War II (1939-1945), the government built many air bases in Arizona because the large number of sunny days provided ideal flying weather. The demand for Arizona's chief products—cattle, copper, and cotton—increased rapidly during the wartime boom. Phoenix doubled in size.

The boom continued into the 1950's. Thousands of veterans who had been stationed in Arizona returned with their families to live there. Air conditioning became widespread and made life pleasant in the desert region. As a result, many people, including large numbers of retired persons, moved to Arizona from the East. The state's population rose by about 50 percent during the 1940's and by about 74 percent in the 1950's.

In 1948, Arizona's Indians won the right to vote. The Arizona Supreme Court struck down parts of the state Constitution that had kept Indians from voting.

Arizona shifted from an agricultural to a manufacturing economy during the 1950's and 1960's. By 1967, the value of industrial production had reached $1 billion, compared with about $600 million for agricultural products. New factories produced a wide variety of electrical and electronic goods, including appliances, computers, and refrigeration equipment. Arizona's warm winters attracted an increasing number of vacationers, and tourism became an even larger industry.

Growth in agriculture, manufacturing, and population during the 1940's and 1950's strained Arizona's water resources. By the 1960's, the state was pumping more water from its underground supply than it was getting from rainfall. In 1963, the Supreme Court of the United States gave Arizona rights to 2,800,000 acre-feet (3.5 billion cubic meters) of water a year from the Colorado River. One acre-foot (1,233 cubic meters) is equal to 1 acre (0.4 hectare) of water 1 foot (30 centimeters) deep and will supply about five city dwellers for one year.

In 1965, Judge Lorna Lockwood was elected chief justice of the Arizona Supreme Court. Her election by her fellow judges made her the first woman in the United States to head a state supreme court.

Arizona's Indians made economic gains during the 1960's. Several tribes started to operate business companies, factories, and industrial and recreational areas on their reservations. Navajo Community College, the first college ever built on an Indian reservation, opened at Many Farms, on the Navajo reservation in northeastern Arizona, in 1969. The college moved to Tsaile in 1973.

The late 1900's. In 1974, construction began on the Central Arizona Project, a system of canals, tunnels, and

Museum of New Mexico

Geronimo and his band of Apache surrendered to U.S. troops at Skeleton Canyon in 1886. Geronimo was captured several times and placed on reservations, but he escaped and returned to fight again and again. Apache fought throughout the Southwest from the late 1600's until 1886.

pipelines designed to ensure the state a sufficient supply of water. The project was completed in 1991. The system covers 336 miles (541 kilometers) and extends from Lake Havasu on the Colorado River to the San Xavier Indian Reservation southwest of Tucson.

In 1975, Raul H. Castro became governor. He was the first Mexican American to be elected to the office.

In 1981, President Ronald Reagan appointed Arizona Judge Sandra Day O'Connor to the Supreme Court of the United States. She became its first woman member.

In the late 1900's, casino gambling became an important source of revenue for many Arizona Indian tribes, funding health, education, and housing programs on reservations. Tribes also used their allotments of Central Arizona Project water to create new agricultural projects or to sell to cities.

In 1988, Governor Evan Mecham was removed from office by the state legislature. He had been charged with illegally lending state money to his automobile dealership and trying to block an investigation into charges that one of his aides had made a death threat against a grand jury witness. The state House of Representatives impeached him. The Senate convicted Mecham on the charges, resulting in his removal from office. Secretary of State Rose Mofford finished Mecham's term, becoming the first woman to serve as Arizona's governor.

In 1997, Governor Fife Symington resigned after being convicted of fraud for filing false financial statements to banks. The actions occurred while he was a real estate developer, and before he was governor. Symington appealed his conviction in 1998. In 1999, the federal appeals court overturned the conviction. Secretary of State Jane Dee Hull, who had replaced Symington, ran in 1998 for a full term as governor. Her election victory made her the first woman to be elected governor of the state.

The early 2000's. The state's economy remained strong through the late 1900's and into the 2000's. But declining copper prices and long labor disputes had led to severe economic problems in several mining areas.

Arizona continued to be one of the nation's fastest-growing states. Its population increased by 35 percent between 1980 and 1990 and by 40 percent between 1990 and 2000. The population growth shifted to cities and away from rural areas.

Arizona, University of, is a state-supported coeducational institution in Tucson, Arizona. It has colleges of agriculture, architecture, arts and sciences, business and public administration, education, engineering and mines, law, medicine, nursing, and pharmacy. It also has a graduate college; a graduate library school; and schools of family and consumer resources, health-related professions, and music. Courses at the University of Arizona lead to bachelor's, master's, and doctor's degrees.

The university's Lunar and Planetary Laboratory, Steward Observatory, and astronomy department operate several observatories. The University Museum of Art includes the Samuel H. Kress Collection of Renaissance paintings and the C. Leonard Pfeiffer Collection of contemporary American art.

The University of Arizona was chartered in 1885. The university opened in 1891.

Critically reviewed by the University of Arizona

Arizona State University is a coeducational state-supported university with campuses in Tempe, Phoenix, and Mesa. The university offers programs in architecture, business, education, engineering, fine arts, law, liberal arts and sciences, nursing, and social work. Arizona State University grants bachelor's, master's, and doctor's degrees. The Center for Meteorite Studies, which is in Tempe, houses one of the world's largest collections of meteorites.

The school was founded in 1885. It became a university in 1958. Critically reviewed by Arizona State University

Ark usually refers to the vessel that sheltered Noah and his family during the *Deluge* (great flood) described in the Bible (Gen. 6). In addition, the word applies to the basket in which Moses's mother hid him. In Jewish synagogues, the ark is the cabinet that holds the scrolls of the *Torah,* the first five books of the Old Testament. *Ark* comes from the Latin word *arca,* meaning *chest, box,* or *coffer.* In Europe, *ark* used to mean a chest or closed basket for storing valuables or other goods. In the United States, *ark* referred to a large flatboat used on western rivers during the expansion of the country.

H. Darrell Lance

See also Ark of the Covenant; Deluge; Noah.

Josh Young, University of Arizona

The University of Arizona campus in Tucson includes Bear Down Gymnasium, *left,* and the main library, *right.*

Ark of the Covenant was a sacred wooden chest described in the Bible as representing God's presence. It was called the Ark of the Covenant because it symbolized the *covenant,* a special agreement that the Israelites made with God at Mount Sinai.

Descriptions of the Ark appear in chapters 25 and 37 of the Book of Exodus. A craftworker named Bezalel built the Ark in the wilderness while the Israelites wandered from Egypt toward the Promised Land (present-day Israel). The Ark was kept in a tent and equipped with poles for carrying. It enclosed the tablets inscribed with the Ten Commandments. See Tabernacle.

The Israelite leader Moses communicated with God before the Ark, and the Israelites carried it into battle to ensure victory. When the Israelites entered the land of Israel, their priests carried the Ark before them over the Jordan River. The Philistines captured the Ark during a battle, but returned it seven months later. King David eventually brought the Ark to Jerusalem in a great procession. His son, King Solomon, installed it permanently in his new Temple in Jerusalem. By the time the Babylonians destroyed the Temple in 587 or 586 B.C., the Ark had disappeared and was no longer mentioned in the Bible. The Ark does appear in later legends. Some people assume the Ark was destroyed by a conquering army. Others claim it is hidden. Lawrence H. Schiffman

Detail (about A.D. 239) from the west wall of the Second Synagogue, Dura Europas, Syria; National Museum of Damascus (Art Resource)

The Ark of the Covenant held the tablets inscribed with the Ten Commandments. The Israelites carried it during their wanderings. The Philistines captured the Ark after the Israelites entered the land of Israel. This fresco shows the Philistines returning the Ark.

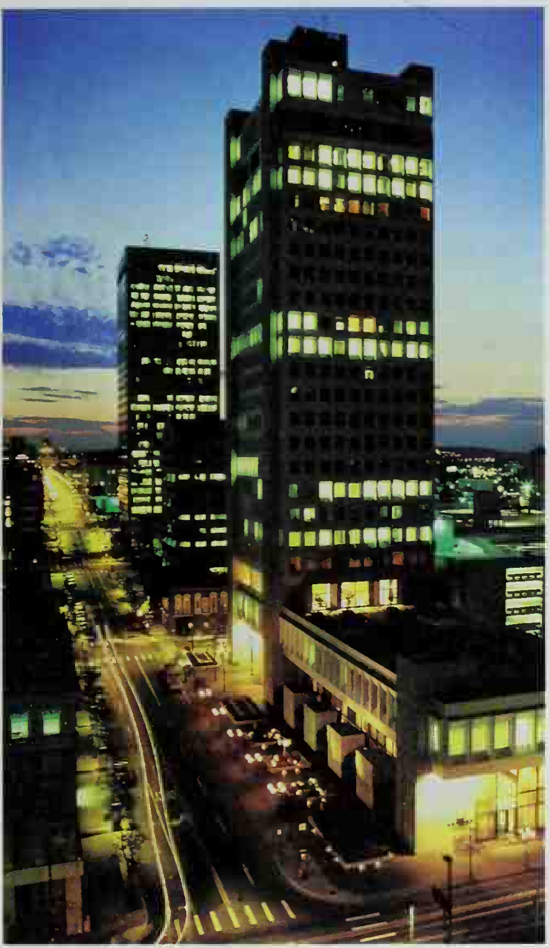
National Park Service

The Buffalo National River flows past massive limestone bluffs in the Ozark Mountains in northern Arkansas. The state's natural beauty and recreational facilities attract large numbers of visitors.

Arkansas *The Natural State*

Arkansas, *AHR kuhn SAW,* one of the Southern States of the United States, is almost evenly divided between the *Highlands* and the *Lowlands.* The Highlands area, in northern and western Arkansas, has scenic mountains, forests, free-flowing streams, and land suitable for raising livestock. The Lowlands area includes a plain along the Mississippi River in eastern Arkansas, sometimes called the Delta, and a plain in southern Arkansas. The Delta has some of the richest farmland in the United States, and the southern plain has extensive pine forests. Arkansas is known as *The Natural State* because of its natural beauty and abundant wildlife.

Little Rock is the capital and largest city of Arkansas. The name *Arkansas* comes from an Indian term for the Quapaw tribe, known as *the downstream people.*



Millions of tourists visit Arkansas every year. Its clear lakes and streams attract many vacationers who enjoy boating and fishing. Arkansas is famous for its spring waters, which many people believe help cure certain ailments. Mammoth Spring is one of the largest springs in the United States. Hot Springs is a famous health center and a national park. Crater of Diamonds State Park, near Murfreesboro, has a diamond mine open to the public. Tourists sometimes find valuable diamonds there and are permitted to keep their finds.

Food processing is the leading manufacturing industry in the state. The production of paper and chemical products is also important. The Fort Smith and the Little Rock areas are the leading manufacturing centers. Service industries employ most of the state's workers. These industries include such activities as education, health care, real estate, retail trade, and transportation. Several large store chains and two leading trucking firms are headquartered in the state.

Farming and mining are also important parts of the economy. Arkansas produces more rice than any other state. It is one of the leading states in raising chickens. Among Arkansas's mineral products, natural gas and petroleum bring in the most income.

Arkansas belonged first to France, then to Spain, and then to France again. The United States acquired the region in 1803. Arkansas was part of the Louisiana Territory until 1812. Then, it belonged to the Missouri Territory until 1819, when the Arkansaw Territory was established. In 1836, Arkansas became the 25th state of the Union.

Dougan, Professor of History at Arkansas State University and author of Arkansas Odyssey: The Saga of Arkansas from Prehistoric Times to Present; *and John C. Hehr, Professor and Associate Dean of the J. William Fulbright College of Arts and Sciences at the University of Arkansas.*

Matt Bradley

Little Rock, the capital and largest city of Arkansas, ranks as the state's main center of transportation and trade. It lies on the south bank of the Arkansas River.

Interesting facts about Arkansas

WORLD BOOK illustrations by Kevin Chadwick

Pivot Rock, near Eureka Springs, balances on a base only one-fifteenth as large as its top.

Pivot Rock

The Basin Park Hotel in Eureka Springs is seven stories tall, but every floor is a "ground" floor. The hotel is built against a hillside, and each story opens onto the hill at a different height.

"The Hanging Judge," Isaac Parker, brought law and order to the frontier from his courtroom in Fort Smith. He served from 1875 until his death in 1896 as judge of the federal court's Western District of Arkansas. Parker was widely known for his harshness. He sentenced 160 men to death, 79 of whom were hanged.

The city of Texarkana is divided by the Arkansas-Texas state line. Texarkana has two city governments—one for the Arkansas side and one for the Texas side. The Texarkana post office building stands in both states. Its address is "Texarkana, Arkansas-Texas."

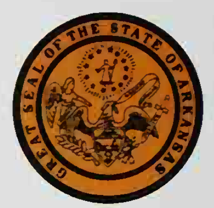
Texarkana post office

The largest federal trout hatchery in the United States is the Norfork National Fish Hatchery in Mountain Home. Each year, this hatchery raises over 2 million trout from eggs until they are about 9 inches (23 centimeters) long. The fish are placed in streams in Arkansas, Missouri, and Oklahoma.

The first jockey to win 100 stakes races worth $100,000 or more was Bill Shoemaker. He won his 100th stakes race at Oaklawn Park in Hot Springs on March 30, 1974.

Matt Bradley

Rice is harvested on many Arkansas farms. The state produces about one-third of the nation's rice. Rice ranks as Arkansas's leading crop, and soybeans rank second.



Arkansas in brief

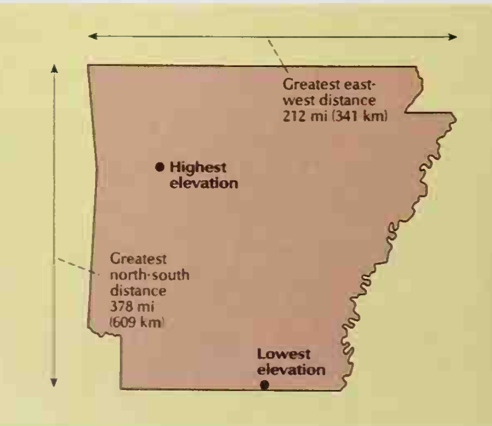
Symbols of Arkansas

On the state flag, adopted in 1924, the diamond-shaped design represents Arkansas as a major diamond-producing state. On the state seal, adopted in 1907, a shield against the breast of an American eagle displays a steamboat, a beehive, a plow, and a sheaf of wheat—all symbols of industrial and agricultural wealth. The Goddess of Liberty stands above the eagle. The Angel of Mercy and the Sword of Justice stand on the sides.

State flag

State seal

Arkansas (brown) ranks 27th in size among all the states and 3rd in size among the Southern States (yellow).



The State Capitol is in Little Rock, the capital of Arkansas since 1821. It is modeled after the U.S. Capitol. Arkansas Post was the capital from 1819 to 1821.

General information

Statehood: June 15, 1836, the 25th state.
State abbreviations: Ark. (traditional); AR (postal).
State motto: *Regnat Populus* (The People Rule).
State anthem: "Arkansas." Words and music by Mrs. Eva Ware Barnett.

Land and climate

Area: 53,183 mi^2 (137,742 km^2), including 1,107 mi^2 (2,867 km^2) of inland water.
Elevation: *Highest*—Magazine Mountain, 2,753 ft (839 m) above sea level. *Lowest*—Ouachita River in Ashley and Union counties, 55 ft (17 m) above sea level.
Record high temperature: 120 °F (49 °C) at Ozark on Aug. 10, 1936.
Record low temperature: −29 °F (−34 °C) in Benton County on Feb. 13, 1905.
Average July temperature: 81 °F (27 °C).
Average January temperature: 40 °F (4 °C).
Average yearly precipitation: 49 in (124 cm).

Important dates

1541 Hernando de Soto [illegible] explored the regio[illegible]

1682 Rene-Robert Cavalier, Sieur de La Salle, claimed the Mississippi Valley for France.

1803 The United States acquired Arkansas as part of the Louisiana Purchase.

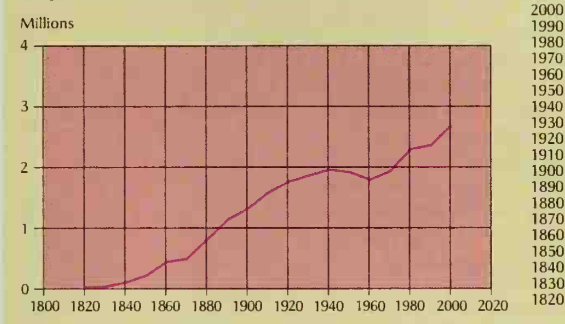
1836 Arkansas became the 25th state on June 15.

People

Population: 2,673,400 (2000 census)

Rank among the states: 33rd

Density: 50 per mi² (19 per km²), U.S. average 78 per mi² (30 per km²)



Distribution*: 53 percent urban, 47 percent rural

The state's official Web site at www.state.ar.us also provides a gateway to much information on Arkansas's economy, government, and history.

1874 The state adopted its present constitution.

1921 Oil was discovered near El Dorado.

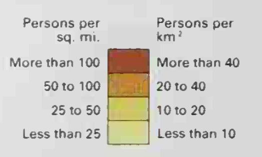
1957 The National Guard helped enforce a court order to integrate Little Rock's Central High School.

1970 The Arkansas River Development program opened the river to navigation from the Mississippi River to Oklahoma.

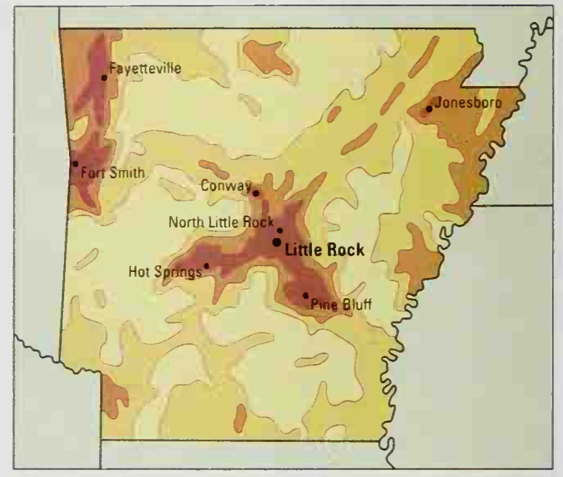
1993-2001 Former Arkansas Governor Bill Clinton was president of the United States.

People

Population. The 2000 United States census reported that Arkansas had 2,673,400 people. The state's population had increased about 14 percent over the 1990 census figure, 2,350,725. According to the 2000 United States census, Arkansas ranks 33rd in population among the 50 states.



About half of the people of Arkansas live in metropolitan areas (see **Metropolitan area**). Four metropolitan areas lie entirely in Arkansas—Fayetteville-Springdale-Rogers, Little Rock-North Little Rock, Jonesboro, and Pine Bluff. The Fort Smith metropolitan area lies mainly in Arkansas and extends into Oklahoma. The Memphis (Tennessee) and Texarkana (Texas)-Texarkana areas lie mainly in Tennessee and Texas, respectively. For the populations of the state's metropolitan areas, see the *Index* to the political map of Arkansas.



Little Rock, the state capital, is the largest city in Arkansas. It has a population of about 183,000. Arkansas has nine other cities with a population of more than 30,000. These cities, in order of population, are Fort Smith, North Little Rock, Fayetteville, Jonesboro, Pine Bluff, Springdale, Conway, Rogers, and Hot Springs.

About 16 percent of the people in Arkansas are African Americans. Other large population groups include people of Irish, German, English, and American Indian descent.

Population density

About half of the people in Arkansas live in one of the state's seven metropolitan areas. Little Rock is the largest city and the state capital.

WORLD BOOK map, based on U.S. Census Bureau data

Arkansas Department of Parks and Tourism

A fisherman on the White River in northern Arkansas displays his catch. The state's rivers and lakes attract many people who enjoy fishing, boating, canoeing, and water skiing.

Matt Bradley

Woodcarvers work in a home craft shop near Mountain View. Woodcarving is a traditional craft among people of the Ozark Plateau region of northern Arkansas.

University of Arkansas at Fayetteville

The University of Arkansas has several campuses throughout the state. The main campus, in Fayetteville, includes Vol Walker Hall, *shown here,* the headquarters for the Department of Architecture.

Schools. When Arkansas became a territory in 1819, Congress set aside land in each county for a general school system. In 1820, the Reverend Cephas Washburn established Dwight Mission, the territory's first school, in Russellville. Washburn and other missionaries taught Cherokee Indian children in Russellville. In 1829, the territorial legislature provided for the construction of schools.

In 1843, seven years after Arkansas became a state, the legislature provided for a public school system. The 1868 Constitution provided for a system of schools for those between the ages of 5 and 21. A law passed in 1909 required all children between 8 and 16 to attend school. This law now affects children from 5 through 16. Voters in 1948 approved a plan to consolidate the state's school districts. As a result, the number of districts was reduced from about 1,600 to a little more than 300.

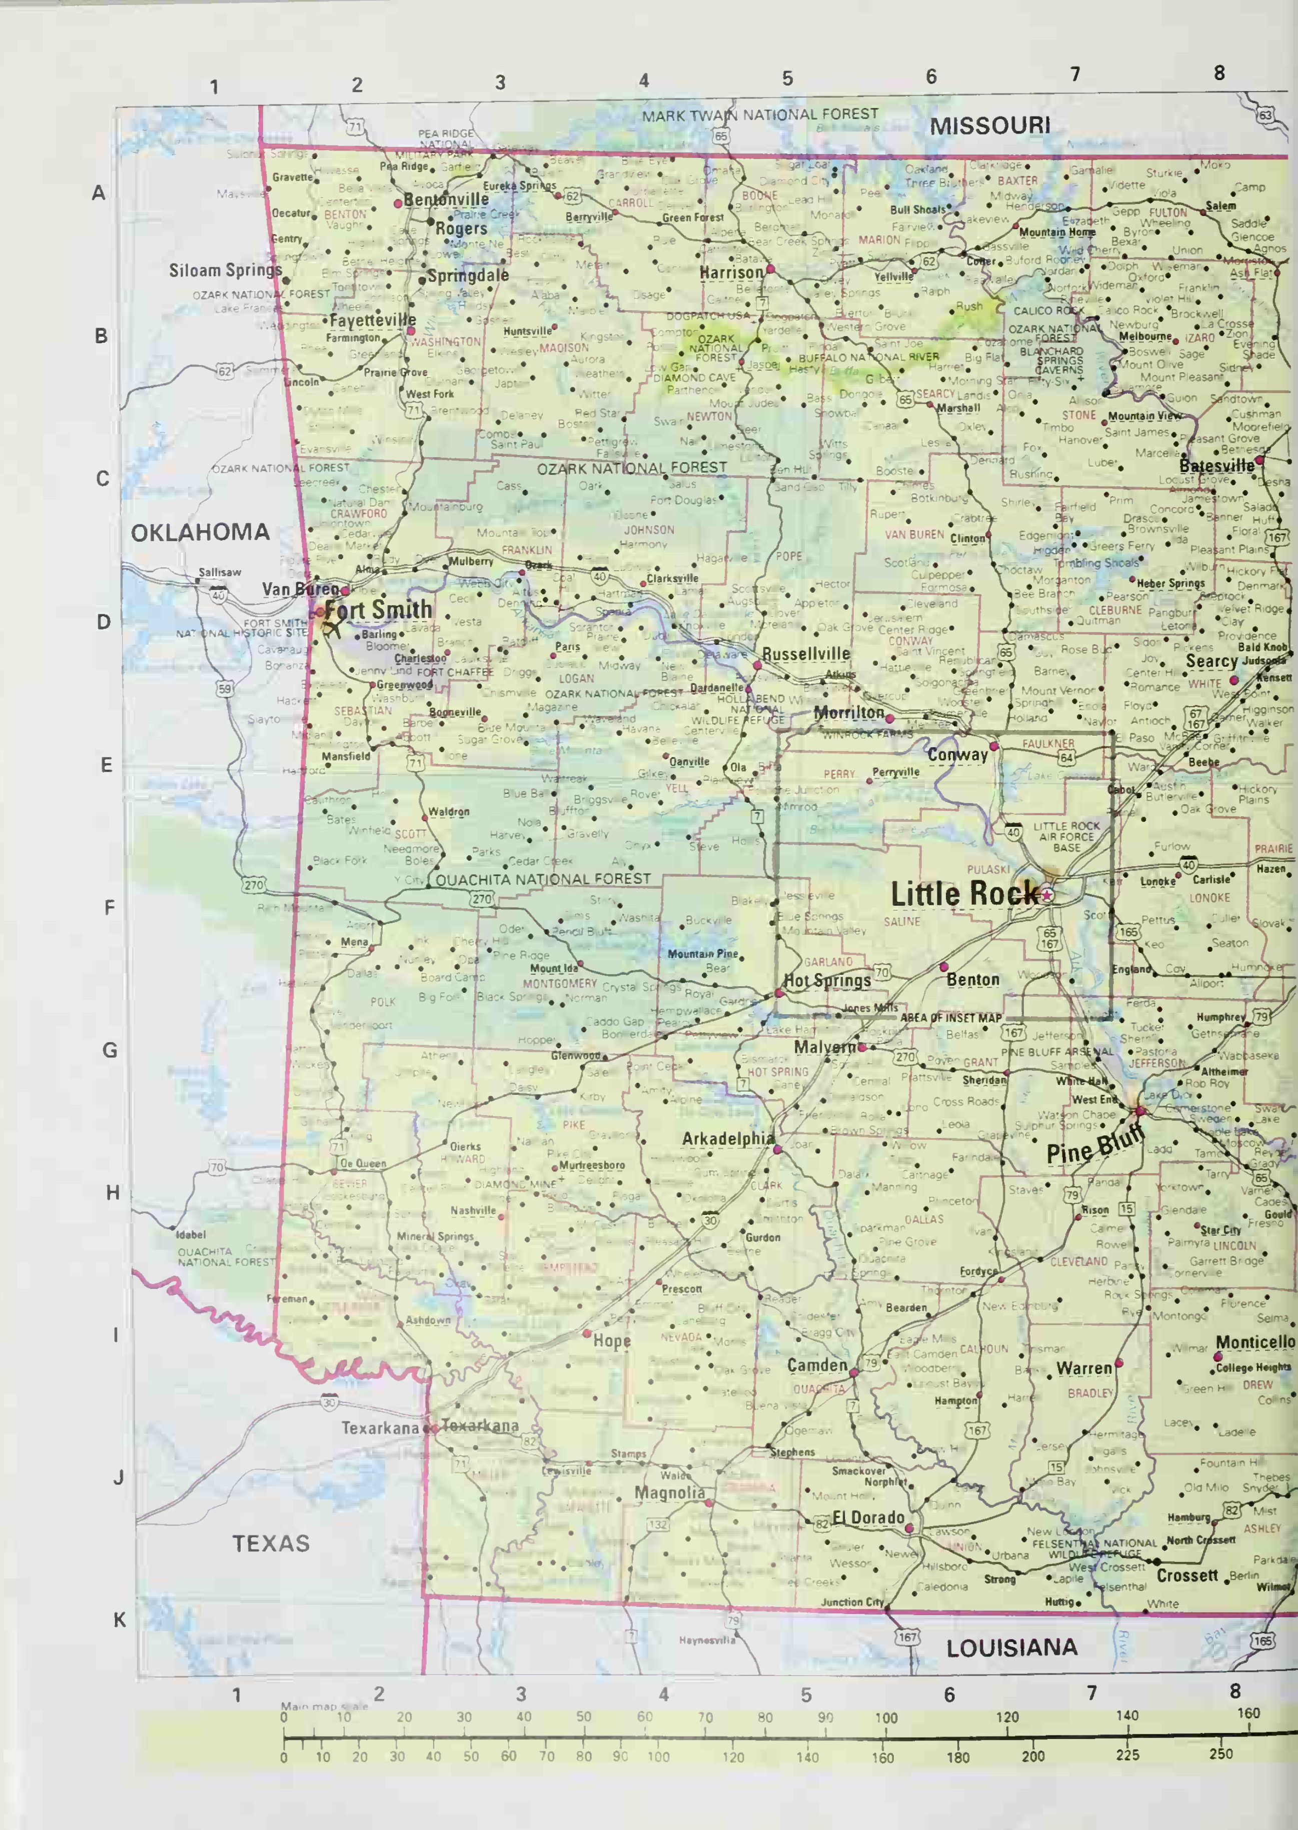
The state department of education administers Arkansas's public school system. The department is governed by the board of education. The board's nine members are appointed by the governor. Their appointments are subject to the approval of the state Senate.

The board of education appoints two directors. One of the directors serves as head of the general education division. The other director serves as head of the vocational technical division. The directors' appointments by the board are subject to the approval of the governor. For information on the number of students and teachers in the state of Arkansas, see **Education** (table).

Libraries. In 1843, William Woodruff founded the state's first subscription library in Little Rock. Members of this library contributed money to buy books, which they could then use without charge. The Helena Public Library, founded in 1888, became the first tax-supported library in the state. Jefferson County established the state's first countywide library service in 1926. In 1935, the Arkansas Library Commission was created by the state legislature. In 1979, the legislature changed the name of the commission to the Arkansas State Library.

Today, Arkansas's public library system includes county libraries and regional libraries. A number of Arkansas cities also operate their own public libraries. The University of Arkansas in Fayetteville has a large collection of materials on Arkansas and the Civil War.

Museums. A number of fine museums are located in Little Rock. They include the Aerospace Education Center, the Arkansas Arts Center, the Historic Arkansas Museum, the Museum of Discovery, the Museum of Science and History, and the Old State House Museum.



Other museums in the state are the Arkansas State University Museum in Jonesboro, Mid-America Science Museum in Hot Springs, Arts and Science Center for Southeast Arkansas in Pine Bluff, Shiloh Museum of Ozark History in Springdale, and University of Arkansas Museum in Fayetteville.

Visitor's guide

Millions of tourists visit Arkansas every year. They enjoy the state's natural beauty, its many recreational facilities, and its historic sites. Nature lovers are drawn to beautiful caverns, limestone cliffs, forests, mountains, and streams. The state's mineral and hot spring waters are considered helpful in treating persons with certain illnesses. Hot Springs has the most famous of these springs. The lakes and streams of Arkansas attract people who like fishing, boating, canoeing, and waterskiing. Hunters track black bears, deer, opossum, and raccoons in the southeastern lowlands and elk in the Ozarks. They stalk game birds and waterfowl in the rice marshes near Stuttgart. The Ouachita and Ozark mountain ranges are popular tourist attractions.

The state's most popular annual events are folk festivals and county fairs. One of the best-known events is the Arkansas State Fair and Livestock Show held in Little Rock in early October.

Fishing on Lake Conway in central Arkansas

Places to visit

Following are brief descriptions of some of Arkansas's many interesting places to visit:

Blanchard Springs Caverns, near Mountain View, have many beautiful formations. Camping, picnicking, and swimming are available nearby.

Crater of Diamonds State Park, near Murfreesboro, has a diamond mine open to the public. Visitors may hunt for diamonds in the mine and can keep what they find. Thousands of diamonds have been found in the Crater of Diamonds, some of great value.

Delta Cultural Center, in downtown Helena, offers exhibits in a Visitors' Center and in a restored 1912 train depot on the culture and heritage of the Arkansas Delta.

Eureka Springs, a Victorian resort town high in the Ozarks, is a favorite spot for tourists. Attractions include a Passion Play, Beaver Lake, a botanical garden, museums, musical entertainment, and a steam-powered train.

MacArthur Park, in Little Rock, honors Douglas MacArthur, commander of Allied forces in the Southwest Pacific during World War II. MacArthur's birthplace, in the park, is now the Museum of Science and History. The Arkansas Arts Center is also located in MacArthur Park.

Ozark Folk Center, in Mountain View, offers craft demonstrations and musical performances by area residents. The complex has a 1,043-seat auditorium, craft shops, a restaurant, a lodge, and a conference center.

National forests and parklands. Arkansas has three national forests: Ouachita in western Arkansas, which the state shares with Oklahoma; Ozark in northern Arkansas; and St. Francis in eastern Arkansas. Next to Ozark National Forest, the Buffalo National River preserves one of the last free-flowing streams in mid-America. Hot Springs National Park, in Hot Springs, includes the famous Hot Springs resort. In addition to its 47 different thermal springs, the park features many hiking trails through the Ouachita Mountains, scenic driving tours, and a variety of recreational activities. Pea Ridge National Military Park in the northwest was the site of a major Civil War battle. Union troops won an important victory there in March 1862. Arkansas Post National Memorial near Gillett marks the first permanent white settlement in Arkansas. Fort Smith National Historic Site in western Arkansas honors one of the first military posts in the American West. Central High School National Historic Site, in Little Rock, is an important civil rights landmark. It was the site of a 1957 confrontation in the struggle to integrate U.S. public schools.

State parks. Arkansas has 51 state parks and museums. For information on the parks, write to Parks Director, Department of Parks and Tourism, One Capitol Mall, Little Rock, AR 72201.

Blanchard Springs Caverns near Mountain View

Land and climate

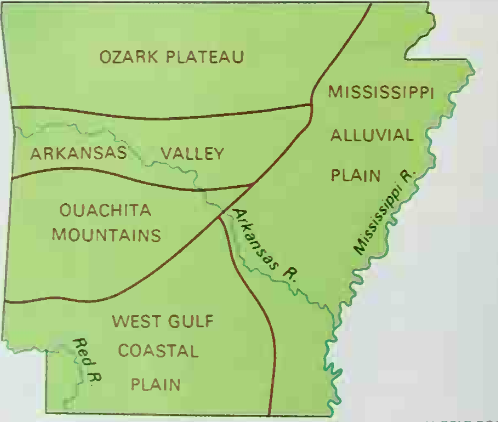
Land regions. Arkansas has five main land regions: (1) the Ozark Plateau, (2) the Ouachita Mountains, (3) the Arkansas Valley, (4) the Mississippi Alluvial Plain, and (5) the West Gulf Coastal Plain. The Ozark Plateau and the Ouachita Mountains make up the portion of Arkansas known as the *Highlands.* The Arkansas Valley divides these two highland regions. The Mississippi Alluvial Plain and the West Gulf Coastal Plain make up the *Lowlands* portion of the state.

The Ozark Plateau is a land region that covers parts of Arkansas, Illinois, Missouri, and Oklahoma. This region is often called the *Ozark Mountains.* In Arkansas, it extends across the northwestern and north-central parts of the state. Rugged hills, deep valleys, and swift streams give the region great beauty. Thick forests and underbrush cover much of the region. Many fruit, livestock, and poultry farms are located in the northeast and northwest sections of the Ozarks. The southern edge of the region has a series of steep, wooded hills called the Boston Mountains. River gorges, 500 to 1,500 feet (150 to 457 meters) deep, wind through these hills.

The Ouachita Mountains region stretches from eastern Oklahoma to central Arkansas. In Arkansas, it consists of a series of parallel ridges and valleys. Blue Mountain rises 2,623 feet (799 meters). Farmers cultivate some of the land. But the Ouachita region is best known for its timber and mineral resources, and for its hot springs. The Ouachita River flows through the central part of the region before curving south to Louisiana. Dams built along the river have created a chain of lakes.

The Arkansas Valley, a broad, rolling valley region, lies between the Ozark Plateau and the Ouachita Mountains. The Arkansas Valley is lower than the highland regions to the north and south, but it has several mountain peaks of its own. Magazine Mountain, the highest point in the state, rises 2,753 feet (839 meters) in the Arkansas Valley. The Arkansas River flows through the center of the region southeast into the Mississippi River. Deposits of coal and natural gas lie beneath the region's fertile fields and pastures.

The Mississippi Alluvial Plain lies along the Mississippi River. This region extends from Missouri south to Louisiana, and it is sometimes called the Delta. It covers the eastern third of Arkansas. Much of the plain is low, level land, covered with rich deposits of soils carried to the region by the Mississippi River and its tributaries. Most of Arkansas's major crops are grown in this region. An excellent system of levees and drainage ditches protects the plain from flooding (see **Levee**). A narrow strip of hills called Crowleys Ridge stretches from north to south through the central part of the Mississippi Alluvial Plain. The ridge is formed of gravel deposits and of wind-blown, yellow mineral particles called *loess.*



The West Gulf Coastal Plain covers sizable parts of Arkansas, Louisiana, and Texas. In Arkansas, it is a large, low region in the southwestern and south-central parts of the state. The coastal plain has pine forests, natural gas and petroleum deposits, and beds of bromine salts. Farmers raise livestock and poultry, and grow fruits and vegetables. The lowest point in the state—55 feet (17 meters) above sea level—is near the Ouachita River at the Arkansas-Louisiana border.

Rivers and lakes. The Mississippi River forms the eastern border of Arkansas. The Arkansas River, the

largest river within the state, flows southeast across Arkansas. The McClellan-Kerr Arkansas River Navigation System was completed in 1970. The system allows boats to travel up the Arkansas River from its mouth at the Mississippi River to Tulsa, Oklahoma. Other important rivers in the state include the Ouachita River in south-central Arkansas, the St. Francis River in the east, the Red River in the southwest, and the White River in northern and eastern Arkansas. The unpolluted, free-flowing Buffalo National River is in the Ozarks.

Lake Chicot, the largest natural lake in the state, is an *oxbow lake,* formed by a river's changing its course (see Oxbow lake). Several smaller Arkansas lakes were also formed in this manner. A number of large lakes have been created by dams built on Arkansas rivers and streams. A chain of artificially created lakes nestles in the Ouachita Mountains. These include Lakes Catherine, Hamilton, and Ouachita. Lakes along the White River in northern Arkansas include Beaver, Bull Shoals, Norfork, and Table Rock. Big Maumelle Lake and Nimrod Lake lie west of Little Rock.

Springs in Arkansas are especially plentiful around the foothills of the Ouachita and Ozark mountains. Every year, thousands of people visit the state's springs in hope that the waters will relieve certain illnesses. Some of the springs contain minerals. Many, however, are known for their purity and their lack of minerals. Eureka Springs in the Ozarks has nearly 65 springs. Mammoth Spring, also in the Ozarks, is one of the largest springs in the United States. About 235 million gallons (890 million liters) of cold water gush from the earth each day. The state's famous Hot Springs consists of 47 different springs that together yield about 1 million gallons (3.8 million liters) of water a day. The temperature of the water remains constant at about 143 °F (62 °C).

Plant and animal life. Forests cover about half of Arkansas. The state's most common trees include ashes, basswoods, buckeyes, elms, hackberries, hawthorns, hickories, hollies, maples, oaks, plums, wild cherries, and willows. Flowering trees include the dogwood, locust, magnolia, red haw, and redbud.

Arkansas has many kinds of wildflowers, including American bellflowers, orchids, passionflowers, water lilies, wild verbenas, and yellow jasmines. Ferns and herbs are plentiful. The fern *Woodsia scopulina,* which grows on Magazine Mountain, is found nowhere else between the Allegheny and Rocky mountains.

Animal life in Arkansas's fields and forests includes black bears, bobcats, deer, foxes, gray and red squirrels, and rabbits. Mountainous regions have minks, muskrats, opossums, raccoons, skunks, weasels, and woodchucks. Arkansas has many varieties of game birds, including pheasants, quail, wild ducks, wild geese, wild turkeys, and woodcocks. Common songbirds include the blue jay, brown-headed nuthatch, brown thrasher, cardinal, goldfinch, mockingbird, painted bunting, phoebe, robin, warbler, and whippoorwill. Reptiles include lizards,

Average July temperatures
The state has warm to hot summers, with most of Arkansas averaging above 80 °F (27 °C). The far north is cooler.

Average yearly precipitation
Arkansas has a rainy climate. The heaviest precipitation generally falls in the southern section of the state.

WORLD BOOK maps

turtles, and many kinds of snakes. The lakes, rivers, and streams are filled with bass, bream, catfish, crappies, drum, perch, pickerel, sturgeon, and trout.

Climate. Arkansas has a warm, moist climate with warm to hot summers and cool winters. The highlands of northern and western Arkansas are cooler than the lower regions to the south and east.

July temperatures average 78 to 80 °F (26 to 27 °C) in northwestern Arkansas and 82 to 84 °F (28 to 29 °C) in the lowlands. Even in summer, the highland regions are cool at night. In January, temperatures average from 36 to 42 °F (2 to 6 °C) in the northwest and from 42 to 48 °F (6 to 9 °C) in the south and east. The lowlands often have warm, sunny days, even in winter. The state's highest recorded temperature, 120 °F (49 °C), was at Ozark on Aug. 10, 1936, and the lowest recorded temperature, −29 °F (−34 °C), was in Benton County on Feb. 13, 1905.

Yearly precipitation averages about 49 inches (124 centimeters). It ranges from about 42 inches (107 centimeters) in the far north-central region to about 54 inches (137 centimeters) in the core of the Ouachita mountain region. Snowfall in Arkansas averages about 6 inches (15 centimeters) a year. The snow occurs mostly in the highlands.

Economy

Service industries of Arkansas, taken together, account for the largest portion of the *gross state product*—the total value of all goods and services produced in a state in a year. However, manufacturing is the single most important economic activity in Arkansas. Food processing is the state's leading manufacturing activity. Wholesale and retail trade form the leading service industry in the state.

Natural resources of Arkansas include fertile soils and rich mineral deposits. The state also has thick forests and abundant water.

Soil. Much of Arkansas has fertile soil. The best farmland is in the Mississippi Alluvial Plain and in the valleys of the Arkansas and Red rivers. The northern part of the Ozark Plateau has good loamy soils. The southern Ozarks and the Ouachita region have silty and sandy soils. Clay loams mixed with gravel are found in southwest Arkansas. The Crowleys Ridge section of eastern Arkansas has wind-deposited loess soils (see Loess).

Minerals. The West Gulf Coastal Plain has petroleum deposits. *Bituminous* (soft) coal and a harder coal called *semianthracite* come from the Arkansas Valley. Natural gas is also found in parts of the valley. Other mined products include bauxite, bromine, clays, gemstones, granite, gypsum, lignite, limestone, marble, quartz, sand and gravel, soapstone, tripoli, and vanadium.

Forests cover more than half of the state. Northwest Arkansas has shortleaf pine and hardwood forests. The southwest has forests of loblolly and shortleaf pines. Most of the eastern forests are hardwood.

Service industries account for the largest portion of the gross state product of Arkansas. Most of the service industries are concentrated in the metropolitan areas.

Wholesale and retail trade form the leading service industry. The wholesale trade of automobiles, farm products, and mined products is important. Major retail businesses in the state include department stores, discount stores, and food stores. Wal-Mart, the nation's largest discount-store chain, is based in Bentonville. Dillard Department Stores is based in Little Rock.

The community, business, and personal services group ranks second among the service industries of Arkansas. Community, business, and personal services include private health care, nursing and rest homes, law firms, motels, and repair shops.

Both (1) government and (2) finance, insurance, and real estate contribute about the same amount to the Arkansas economy. Government services include the operation of public schools and hospitals, and military bases. Little Rock Air Force Base is the largest military installation in Arkansas. Little Rock is the state's chief financial center.

Transportation, communication, and utilities rank fifth among Arkansas service industries. Two leading U.S. trucking companies are headquartered in the state. They are J. B. Hunt, located in Lowell, and ABF Freight System, in Fort Smith. Several railroads and many other trucking companies operate in Arkansas. Telecommunications companies are the most important part of the communications sector. Alltel, a major telecommunications firm, is based in Little Rock. Utilities provide electric, gas, and water service. More information about transportation and communication appears later in this section.

Manufacturing. Goods manufactured in the state have a *value added by manufacture* of about $21 billion yearly. This figure represents the increase in value of raw materials after they become finished products.

Food products are the state's leading kind of manufactured items in terms of value added by manufacture. They include animal feeds, bakery goods, canned vegetables, cottonseed oil, meats, milk, poultry, rice, and soft drinks. Key food processing locations include Fort

Production and workers by economic activities

Smith, Jonesboro, Little Rock, North Little Rock, and Springdale. Tyson Foods, based in Springdale, is the world's largest poultry producer and processor. Other large food-processing plants operate in Batesville, Fayetteville, Hope, Nashville, Pine Bluff, Russellville, Stuttgart, Van Buren, and several other cities.

Paper products rank second among manufactured products in Arkansas. The state's paper products include paperboard boxes and paper. Paper and paperboard mills are located in Ashdown, Crossett, Morrilton, Pine Bluff, and many other towns throughout the state.

Other types of products manufactured in Arkansas include chemicals, electrical equipment, fabricated metal products, machinery, plastics and rubber products, transportation equipment, and wood products. Industrial and agricultural chemicals are the state's most valuable chemical products. Leading kinds of electrical equipment include electric motors, household appliances, measuring devices, and lighting devices. Valves and pipe fittings are the most valuable types of fabricated metal products manufactured in Arkansas. Heating and cooling equipment and machinery for use in the metalworking industry are the major types of machinery. A large tire factory operates near Texarkana. The state's transportation products include motor vehicle parts and aerospace parts. Lumber, plywood, and pulp paper are the leading types of wood products made in the state.

Agriculture. Arkansas has about 50,000 farms. Farmland covers about half of the state's land area.

Livestock products provide about 60 percent of farm income. *Broilers* (chickens from 5 to 12 weeks old) are the leading farm product. Arkansas is one of the leading states in the production of broilers. The chief broiler-raising regions include the northwestern part of the state, the Arkansas Valley in the southwest, and the west-central area of Independence County.

Beef cattle are the second most valuable livestock product, followed by eggs, turkeys, hogs, and milk. Beef cattle are raised in most parts of the state. Dairy farming is centered in the Ozark Plateau and near Little Rock and Fort Smith. Farmers also raise catfish on fish farms.

Crops account for approximately 40 percent of the income from farm products. Rice is the most valuable crop grown in Arkansas. The state is the leading U.S. producer of rice. Rice is grown mainly in the Mississippi Alluvial Plain region in eastern Arkansas. Some farmers flood their rice fields and raise fish in them.

Soybeans are the second most valuable crop. Arkansas ranks among the leading soybean-producing states. Soybeans are grown throughout the state, especially in the east.

Other leading crops in Arkansas include cotton and wheat. These crops are grown in many parts of the state. Hay is an important crop in the northwestern part of the state. Arkansas farmers grow corn, which is used primarily as food for livestock. Grain sorghum and vegetable crops are also important.

Mining. Natural gas is the leading mined product of Arkansas. Petroleum ranks second. Johnson and Sebastian counties in northwest Arkansas produce the most natural gas. The state's largest oil fields lie near the southern border.

Bromine and crushed stone are also major mined products in Arkansas. Bromine is obtained from underground brines in the south-central part of the state. Several areas in Arkansas have stone quarries. The state's other mined products include cement, clays, coal, gypsum, limestone, novaculite, quartz, sand and gravel, soapstone, tripoli, and vanadium.

Electric power. Plants that burn coal generate about 55 percent of the state's electric power. Nuclear plants produce about 30 percent of the power. Hydroelectric plants and plants that burn natural gas produce most of the rest of the state's electric power.

Transportation. The earliest settlements in Arkansas were built along rivers. Flatboats and keelboats provid-

Economy of Arkansas

This map shows the economic uses of land in Arkansas and where the state's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

WORLD BOOK map

ed early transportation to New Orleans, St. Louis, and other market centers. Steamboats began to appear in the 1820's. Paths and trails were built from the river settlements to other parts of the region. Stagecoach lines were established in the state in the 1830's. The main early road in Arkansas ran from Memphis to Little Rock and Van Buren. Railroad building in Arkansas began in the 1850's. The earliest railroads were the Memphis and Little Rock, and the Mississippi, Ouachita & Red River. Water transportation in Arkansas declined in the late 1800's, but railroad construction increased. A state highway commission was created in 1913.

Today, Arkansas has about 94,000 miles (151,000 kilometers) of roads and highways. Interstate 40, which links Little Rock with Fort Smith and Memphis, and Interstate 30, which runs from Little Rock to Texas, are the busiest highways. Several railroads provide freight service, and passenger trains serve Little Rock, Texarkana, and Walnut Ridge. Little Rock has the state's largest airport.

Waterways connect Arkansas with cities in neighboring states. In 1970, a federal navigation project opened the Arkansas River to barge traffic from the Mississippi River to Oklahoma. Fort Smith, Little Rock, and Pine Bluff became river ports.

Communication. The *Arkansas Gazette,* the state's first newspaper, was founded in Arkansas Post in 1819. It was moved to Little Rock in 1821. In 1991, the *Gazette* was sold to the *Arkansas Democrat* of Little Rock, which became known as the *Arkansas Democrat Gazette.* The *Arkansas Democrat Gazette* is the state's leading paper. Other major papers in Arkansas include the (Fort Smith) *Southwest Times Record,* the (Rogers) *Morning News of Northwest Arkansas,* and the *Jonesboro Sun.* Arkansas has about 130 newspapers, including about 25 dailies. The state's publishers also produce about 40 periodicals.

The state's first radio station, WOK, began broadcasting in Pine Bluff in 1920. The first television station, KATV, opened in Little Rock in 1953. Today, Arkansas has about 160 radio stations and 20 television stations. Cable TV systems and Internet providers serve many Arkansas communities. Residents in some rural areas rely on satellite services.

Government

Constitution. The present Constitution of Arkansas was adopted in 1874, after the Reconstruction period ended in the state. Earlier constitutions had been adopted in 1836, 1861, 1864, and 1868.

Amendments (changes) to the Constitution may be proposed in three ways. *Legislative amendments* are introduced by members of the state legislature. They must be approved by a majority of each house of the legislature. *Initiative amendments* are introduced through petitions signed by a specified number of voters. Amendments can also be proposed by *constitutional conventions.* Before a constitutional convention can meet, it must be approved by the voters. Every amendment must be approved in an election by a majority of the voters who cast ballots on the amendment.

Executive. The governor of Arkansas serves a four-year term and may serve no more than two terms.

Other elected state officers are the lieutenant governor, secretary of state, attorney general, treasurer, auditor, and land commissioner. These officials are also elected to four-year terms and may serve no more than two terms. The governor appoints the adjutant general, controller, and the heads and members of various departments and commissions. Many of these appointments must be approved by the state Senate.

Legislature, called the General Assembly, consists of a 35-member Senate and a 100-member House of Representatives. Each of the state's 35 senatorial districts elects one senator. Each of the 100 representative districts elects one representative. Senators are elected to four-year terms and may serve no more than two terms. Representatives are elected to two-year terms and may serve no more than three terms.

Legislative sessions begin on the second Monday in January of odd-numbered years. Legislative sessions last up to 60 calendar days. Sessions may be extended by a two-thirds vote of both houses of the legislature for an unlimited period of time. The governor may call the legislature into special session, which has no time limit.

In 1965, a federal district court ordered the state board of apportionment to *reapportion* (redivide) the legislature to provide equal representation based on population. The governor, secretary of state, and attorney general make up the board of apportionment. The board drew reapportionment plans for the House and Senate. The federal district court and the Supreme Court of the United States approved the plans. The state board of apportionment has reapportioned the Arkansas legislature after every federal census since 1970.

Courts. The highest court in Arkansas is the state Supreme Court. It consists of a chief justice and six associate justices, all elected to eight-year terms. The state is divided into 23 circuit court districts. Voters from these districts elect circuit court judges to six-year terms.

Each county in Arkansas has a county court. County court judges are elected to two-year terms. Municipal court judges are elected to either two- or four-year terms, according to local law. Justices of the peace and common pleas court judges serve two-year terms.

Local government. Each of the state's 75 counties is administered by the county judge. The judge approves county expenditures and presides over the quorum court, a legislative group whose duties include approving the county budget. The county judge and members of the quorum court are elected to two-year terms. Other county officials include the assessor, clerk, medical examiner or coroner, sheriff, surveyor, treasurer, and the collector, who is the sheriff in smaller counties.

Most Arkansas cities have the mayor-council form of government. Some cities use the council-manager form.

Revenue. Taxes are the largest source of the state government's *general revenue* (income). They account for more than half of the state's revenue. They include a general sales tax, income taxes, license fees, and taxes on alcoholic beverages, horse racing, insurance, motor fuels, and tobacco products. Federal grants are the second largest source of revenue. They account for nearly a third of the state government's revenue.

Politics. The Democratic Party controlled Arkansas politics from the late 1800's until the 1960's. From 1874 until 1966, no Republican was elected governor of the state nor elected to a seat in the U.S. House of Representatives. In addition, from the 1870's until 1996, no Republican was elected to the U.S. Senate from Arkansas. However, the Republican Party has gained strength in the state since the 1960's.

In the 1968 presidential election, American Independent Party candidate George C. Wallace carried Arkansas. It was the first time in a hundred years that the state did not support a Democratic presidential candidate. In 1972, Richard M. Nixon became the first Republican presidential candidate since 1868 to win Arkansas's electoral votes. For Arkansas's voting record in presidential elections, see **Electoral College** (table).

The governors of Arkansas

	Party	Term
James Sevier Conway	Democratic	1836-1840
Archibald Yell	Democratic	1840-1844
Thomas S. Drew	Democratic	1844-1849

David H. Pryor	Democratic	1975-1979
Bill Clinton	Democratic	1979-1981
Frank D. White	Republican	1981-1983
Bill Clinton	Democratic	1983-1992
Jim Guy Tucker	Democratic	1992-1996
Mike Huckabee	Republican	1996-

*In 1864 and 1865, Arkansas had two governors—one for the Confederate State of Arkansas, one for the Union State of Arkansas.

History

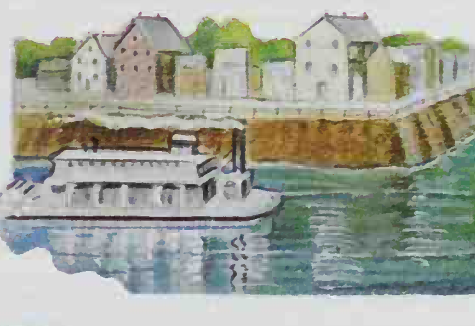
Early days. Indians lived in the Arkansas region about 12,000 years ago. Early European explorers found three principal tribes—the Caddo, Osage, and Quapaw—in the region.

Exploration and settlement. In 1541, Hernando de Soto, a Spanish explorer, led an expedition that reached Arkansas. The Europeans failed to find the gold they were searching for, but historians believe the expedition introduced diseases that killed much of the population. In 1673, Father Jacques Marquette and Louis Jolliet of France traveled down the Mississippi to the mouth of the Arkansas River, where they met Quapaw Indians. In 1682, René-Robert Cavelier, Sieur de La Salle, claimed the Mississippi Valley for France. La Salle made a grant of land to Henri de Tonty, who built a trading station called the Post of Arkansas (also known as Arkansas Post), near the mouth of the Arkansas River in 1686.

In 1717, France gave exclusive trading rights in Louisiana to Scottish banker John Law. To finance his company, Law developed a plan called the "Mississippi Scheme" (see **Mississippi Scheme**). Law's company eventually collapsed in a financial disaster called the "Mississippi Bubble." But the scheme brought many settlers to Louisiana. About 100 Europeans and a few African slaves settled near the Post. Most of the settlers left, but some farmers remained.

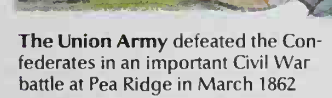
In 1762, during the French and Indian War, France ceded Spain the land west of the Mississippi River. This land included the Louisiana Territory. In 1800, Spain transferred the Louisiana Territory back to France. In 1803, the United States bought the Louisiana Territory from France. See **Louisiana Purchase**.

Territorial years. In 1812, the southern part of the Louisiana Territory was made the state of Louisiana. The northern part, including Arkansas, became the Missouri Territory. In 1817, the U.S. government established Fort Smith in what is now northwestern Arkansas to keep peace among Indian tribes in the region. In 1819, the government created the Arkansaw Territory. It included present-day Arkansas and part of what is now Oklahoma. The town of Fort Smith grew up around the fort. Van Buren developed nearby. The town of Washington (now a state park) became an important stopping point on the route to Texas.



In the early 1800's, northwestern Arkansas became a temporary home to large numbers of Cherokee Indians.

Historic Arkansas



Louis Jolliet and Jacques Marquette explored the Mississippi River in 1673 as far south as the mouth of the Arkansas River. Jolliet, a French-Canadian fur trader, and Marquette, a French missionary, traveled in birchbark canoes.

Fort Smith became an important supply base for goldseekers during the California gold rush of 1849.

The Union Army defeated the Confederates in an important Civil War battle at Pea Ridge in March 1862

Hattie Caraway of Arkansas in 1932 became the first woman elected to the United States Senate.

Douglas MacArthur, a famous U.S. Army general, was born at the "Old Arsenal" in Little Rock in 1880.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Arkansas

1541 Hernando de Soto of Spain led an expedition to the region.

1673 Father Jacques Marquette and Louis Jolliet of France explored the Mississippi River in the region.

1682 René-Robert Cavelier, Sieur de La Salle, claimed the Mississippi Valley for France.

1686 Henri de Tonty, a friend of La Salle, established a trading station at the mouth of the Arkansas River.

1803 The United States acquired Arkansas as part of the Louisiana Purchase.

1819 The Arkansaw Territory was formed from the Missouri Territory.

1836 Arkansas became the 25th state on June 15.

1861 Arkansas seceded from the Union.

1868 Arkansas was readmitted to the Union.

1874 Arkansas adopted its present constitution.

1921 The first oil well was drilled in the El Dorado field.

1957 National Guard units and federal troops helped enforce a court order to integrate Little Rock's Central High School.

1964 Orval E. Faubus became the first Arkansas governor to be elected to a sixth consecutive term.

1970 The Arkansas River Development Program opened the river to navigation from the Mississippi River to Oklahoma.

1993-2001 Former Arkansas Governor Bill Clinton served as the 42nd president of the United States.

But the Cherokee and other eastern tribes were forcibly moved to Indian Territory (present-day Oklahoma) during the 1830's (see Trail of Tears).

Statehood and the Civil War. On June 15, 1836, Arkansas was admitted to the Union as the 25th state. The nation was then engaged in a great debate over the question of slavery. By 1860, Arkansas had a white population of 435,450 and about 110,000 slaves. Many slaves worked on cotton plantations in the Arkansas lowlands.

Abraham Lincoln, who opposed slavery, was elected president in 1860. Several Southern slave states then *seceded* (withdrew) from the Union and formed the Confederacy. Arkansas voters at first rejected secession, but the state joined the Confederacy soon after the Civil War began on April 12, 1861.

Arkansas sent troops to fight in Mississippi at the Battle of Wilson's Creek in August 1861. The Confederates won the battle. The Union Army entered the state and defeated the Confederates at the Battle of Pea Ridge in March 1862. In November 1862, Union soldiers defeated the Confederates at the Battle of Prairie Grove.

On Sept. 10, 1863, the Union Army took Little Rock. The Confederates then moved their capital to Washington in southwestern Arkansas. In 1864, Arkansans loyal to the Union wrote a new state constitution, establishing a Union government in Little Rock and abolishing slavery. But much of the state was not controlled by either the Union or the Confederacy. Lawless *bushwhackers* robbed and murdered many people.

Reconstruction. During the Reconstruction period that followed the war, ex-Confederates dominating the Arkansas legislature refused to rejoin the Union. The U.S. Congress put Arkansas under military control. Federal troops occupied the state from 1867 to 1874.

Arkansas was readmitted to the Union in 1868. In that year, the state adopted a new constitution, giving black men the right to vote but denying it to ex-Confederates. The Republican government tried to speed economic development, establish schools, and protect the civil rights of ex-slaves. Violence broke out between Republicans and Democrats and between whites and blacks.

Arkansas Gazette

Conflict over school integration occurred at Central High School in Little Rock in 1957. President Dwight D. Eisenhower sent United States Army troops to the school to enforce a federal court order to integrate the school.

Antiblack groups such as the Ku Klux Klan spread terror.

In 1872, two Republicans clashed in the contest for governor. Elisha Baxter defeated Joseph Brooks, but Brooks charged fraud and claimed that he had won. On April 15, 1874, Brooks forced Baxter to leave the Statehouse at gunpoint. Rival supporters of the men clashed in what was called the Brooks-Baxter War. On May 15, 1874, President Ulysses S. Grant proclaimed Baxter the governor. Later in 1874, the state adopted a new constitution, which, though much amended, is still in use.

The late 1800's. New railroads crisscrossed Arkansas in the late 1800's. Timber companies moved to the state to harvest the rich forest resources. New levees along the rivers and drainage ditches produced a land boom in the Delta. Bauxite was discovered near Little Rock in 1887, and mines opened.

The early 1900's brought continued development. Improved schools, medical care, and other government services were available at least in the towns. Rice growing was introduced in eastern Arkansas and began to replace cotton. In 1921, oil was found near El Dorado. The state's first large hydroelectric dam was built in 1924.

However, agricultural prices fell after 1920, and many Arkansans lost their farms. The state was also affected by a destructive Mississippi flood in 1927, by a drought in 1930, and by the Great Depression of the 1930's. In 1934, after the price of cotton fell below the cost of production, some rebellious Arkansas farmers organized the short-lived Southern Tenant Farmers Union at Tyronza. But conditions remained poor for tenant farmers and sharecroppers.

In 1932, an Arkansas woman, Hattie Caraway, became the first woman elected to the United States Senate. She won a special election held shortly after the death of her husband, U.S. Senator Thaddeus Caraway.

The mid-1900's. Farming and mining expanded in Arkansas during World War II (1939-1945). Soon after the war, the state began to shift from an agricultural to an industrial economy. Many farmworkers were replaced by the increased use of farm machinery. Manufacturing grew, but not fast enough to provide jobs for all these unskilled workers. Many left Arkansas to find jobs in other states. In spite of these problems, the number of Arkansas manufacturing plants more than doubled during the 1940's and 1950's. A number of plants were attracted to the state by the Arkansas Industrial Development Commission, which was established in 1955.

In 1957, Arkansas became a center of the controversy over school integration. The Supreme Court of the United States had ruled in 1954 that compulsory segregation in public schools is unconstitutional. In 1957, a federal court ordered Central High School in Little Rock to integrate. Governor Orval E. Faubus sent the Arkansas National Guard to block integration. President Dwight D. Eisenhower then put the National Guard under federal control and sent U.S. Army troops to enforce the court order. By 1970, most Arkansas schools and other public facilities were integrated to a degree.

In the early 1960's, Arkansas's manufacturing income passed its farm income for the first time. Faubus was reelected governor in 1964 to a sixth consecutive term. No other Arkansas governor had served more than three terms. In 1967, Winthrop Rockefeller became Arkansas's first Republican governor since Reconstruction days.

The late 1900's. The Arkansas River Development Program was completed in 1970. The development, renamed the McClellan-Kerr Arkansas River Navigation System, opened the river to navigation across the state from the Mississippi River into Oklahoma.

Bill Clinton, a Democrat who had been elected governor of Arkansas five times, was elected president of the United States in 1992 and reelected in 1996.

In May 1996, Governor Jim Guy Tucker of Arkansas was convicted of conspiring to defraud financial institutions and win illegal loans. He resigned from office. He was sentenced to probation and community service.

The early 2000's. Arkansas faces such problems as reducing air and water pollution, providing enough energy for the state, improving its public education, and strengthening its unstable farm economy. State officials have succeeded in some attempts to promote foreign trade and attract new industry. The northwest section has thrived, and retirees have found this region attractive. However, many Delta counties have lost population.

Arkansas has made repeated attempts to bring its schools up to the national average, but problems of funding remain. Private schools and home-schooling have increased in popularity. New junior colleges and new branches of existing colleges have expanded educational opportunities. Michael B. Dougan and John G. Hehr

Arkansas, University of, is a coeducational land-grant school with campuses in Fayetteville, Little Rock, Monticello, and Pine Bluff, Arkansas. It is supported chiefly by state and federal funds.

The main campus is at Fayetteville. It has the J. William Fulbright College of Arts and Sciences and colleges of agriculture and home economics, business administration, education, and engineering. It also has a graduate school, school of law, school of architecture, main agricultural experiment station, biomass research center, bureau of business and economic research, and engineering experiment station. Also at Fayetteville are the University of Arkansas Press, the Fulbright Institute of International Relations, and the Center for Arkansas and Regional Studies.

The campus of the University of Arkansas at Little Rock has colleges of arts, humanities, and social sciences; business administration; education; professional and public affairs; and science and engineering technology. It also has a graduate school, a school of law, and the Center for Research and Public Service. The University of Arkansas for Medical Sciences is also in Little Rock. Education and liberal arts courses are offered in Monticello and Pine Bluff.

The University of Arkansas was founded in 1871 in Fayetteville. The university offers bachelor's, master's, and doctor's degrees.

Arkansas River, *AHR kuhn SAW* or *ahr KAN zuhs,* is a stream of the south-central United States. It is the longest river that flows into the Mississippi-Missouri river system. The total length of the Arkansas is 1,459 miles (2,348 kilometers). The waters from an area of about 160,500 square miles (415,690 square kilometers) drain into it. The river rises on the east slope of the Rocky Mountains, in the central part of Colorado near Leadville. It flows southeast through Kansas, Oklahoma, and Arkansas. The Cimarron, Canadian, and White rivers

WORLD BOOK map

Location of the Arkansas River

flow into the Arkansas, and drain parts of New Mexico, Texas, Oklahoma, Arkansas, and Missouri.

The Arkansas has a rapid current as it flows through mountain valleys and canyons. One of the rocky canyons worn by the Arkansas is the Royal Gorge. Its walls rise more than 1,000 feet (300 meters). Cities that are located on the banks of the river include Pueblo, Colorado; Wichita, Kansas; Tulsa, Oklahoma; Muskogee, Oklahoma; Fort Smith, Arkansas; and Little Rock, Arkansas. The river is named for the Arkansas Indians.

The flow of water on most of the Arkansas River is controlled by 11 dam and reservoir projects. These projects are intended primarily for flood control. They also make it possible to improve navigation and generate water power. John G. Hehr

Arkhangelsk, *ahr KHAHN gehlsk* (pop. 367,200), is one of the largest far-northern cities in the world. It is also called Archangel (pronounced *AHRK AYN juhl).* Arkhangelsk lies about 100 miles (160 kilometers) below the Arctic Circle in Russia, where the Dvina River flows into the White Sea. The city extends about 25 miles (40 kilometers) along the shores of the islands in the river's delta. For the location of Arkhangelsk, see Russia (political map).

Arkhangelsk is a center for the lumber industry and a major port, though the harbor is frozen from November through May, and icebreakers must be used. The city exports lumber, resin, turpentine, and furs. A railroad connects Arkhangelsk with Russian cities in the south.

Arkhangelsk was founded in 1583 as *Novo-Kholmogory.* Its Cathedral of the Archangel Michael was built between 1685 and 1699. The city declined during the 1700's and 1800's, but regained importance after the railroad was built in 1897. During World War II (1939-1945), Arkhangelsk was an important northern port for receiving supplies from the Allies. Zvi Gitelman

Arkwright, Sir Richard (1732-1792), was a British inventor and manufacturer. In 1769, he patented a spinning machine, which was called the *water frame* because water powered it. Sets of rollers turning at different speeds drew cotton from the carding machine, which straightened out the fibers. Spindles then twisted the cotton into thread. The water frame made hard, firm, and rather coarse thread.

Arkwright and two manufacturers started cotton mills that combined the various manufacturing processes of machine carding, drawing, roving, and spinning in one operation. Such organization of manufacturing processes contributed to the development of modern factories.

In 1781, Arkwright's patent was challenged and finally canceled on the grounds of previous invention and deliberately vague and confusing specifications. It is now generally agreed that while Arkwright knew of earlier work on the machine, he added mechanical details that made it work. But his prosperity did not suffer seriously when he lost his patent. His experience and business ability helped him keep his advantage. He was knighted in 1786 and died a wealthy man on Aug. 3, 1792.

Arkwright was born on Dec. 23, 1732, in Preston. He became a barber's apprentice and developed a method of dyeing hair, which he sold to wigmakers. Arkwright then spent the money that he gained from this on his invention. Richard F. Hirsh

Arlington National Cemetery is one of the largest and most famous national cemeteries in the United States. It covers 624 acres (253 hectares) in Arlington, Virginia, across the Potomac River from Washington, D.C. The cemetery surrounds Arlington House, The Robert E. Lee Memorial, which was the home of General Robert E. Lee of the Confederate Army. It occupies land that was once a part of the estate of Lee's wife, Mary Custis Lee. The United States government made Arlington a national cemetery in 1864. The Department of the Army administers it.

Space in the cemetery is available for honorably discharged winners of the Air Force Cross, Distinguished Service Cross, Distinguished Service Medal, Medal of Honor, Navy Cross, Purple Heart, or Silver Star; members of the armed services who die on active duty; certain disabled veterans; members of the armed forces who have served long enough to be officially retired; and honorably discharged veterans who have held a federal elective office or a Cabinet-level position, or who have served on the Supreme Court. Their wives or husbands and their minor children are also eligible. Until 1967, all honorably discharged veterans could be buried in the cemetery.

The Tomb of the Unknowns of World Wars I and II,

Arm is the upper limb of a human being. Properly, the arm is only the part between the shoulder and the elbow. The portion of the arm below the elbow is the *forearm.*

The arm contains one large bone, the *humerus.* Shoulder muscles are attached to its upper portion. Two flexor muscles bend the upper limb at the elbow. These are the *biceps brachii* and the *brachialis.* Two extensor muscles, the *triceps brachii* and the *anconeus,* straighten the upper limb. The forearm contains two bones, the *radius* and the *ulna.* Attached to these are 19 muscles that move the wrist and fingers.

WORLD BOOK illustration by Leonard Morgan

The arm contains three bones—the humerus, the radius, and the ulna. It also contains the biceps and triceps muscles.

Scientists sometimes call the forelimbs of animals arms. Each kind of animal has arms specially suited to its own needs. However, all arms follow the same basic pattern. The wings of birds and bats, the flippers of seals and whales, and the fins of some fish are all variations of the arm. Because of the complex functional capabilities of their hands, human beings can use their arms for many more purposes than can any other animal.

Leslie S. Matthews

Armada. See Spanish Armada.

Armadillo, *AHR muh DIHL oh,* is any of several small American mammals with bony plates in their upper body skin. They usually eat insects, earthworms, spiders, and land snails. Armadillos are found from Argentina northward to the south-central and southeastern parts of the United States. The animal has strong claws, which it uses to dig tunnels and burrows in the ground. It uses its long, narrow tongue to lick up insects. Because the armadillo has only small teeth well back in its mouth, it cannot bite in self-defense.

Francisco Erize, Bruce Coleman Ltd

The nine-banded armadillo has a protective shell of nine narrow bands of bony plates that slide upon one another.

The armadillo's shell is its best protection. The shell is made up of many small plates of bony armor fitted closely together. It is hard and stiff, but is jointed across the animal's back. This jointing allows armadillos of one genus to curl themselves up into a hard tight ball with the shell on the outside and the head and feet tucked in out of harm's way. Few animals are then able to get a grip on the armadillo with their teeth or claws. But the armadillo hides in its shell only as a last resort. It usually hurries into its burrow at the first sign of danger. When an armadillo is too far from its burrow to hide there, it may dig itself rapidly into the ground if it has time.

The nine-banded armadillo is the only species found in the United States. The hinges of its shell consist of nine narrow bands of armor that slide upon one another. This armadillo is about 2 feet (61 centimeters) long, including its tail, and weighs up to 15 pounds (6.8 kilograms). The female gives birth to four babies at a time, always of the same sex.

Other armadillos, found in countries farther south, have three or six bands across the back instead of nine. Armadillos are the only known animal host for the bacterium that causes leprosy in human beings. For this reason, armadillos are important in leprosy research.

Scientific classification. Armadillos make up the family Dasypodidae. The scientific name for the nine-banded armadillo is *Dasypus novemcinctus.* Frank B. Golley

Armageddon, *AHR muh GEHD uhn,* is a Greek word taken from the Hebrew *Har-Megiddo,* which probably means *Mount Megiddo.* In the Bible, the Book of Revelation names Armageddon as the place where the rulers of the world will fight the last great battle between good and evil.

No Mount Megiddo has been identified. However, an ancient city called *Megiddo* was located in the mountains of northern Israel, across the Plain of Esdraelon from Nazareth. Many battles were fought on this plain in Biblical times. Archaeologists from the Oriental Institute in Chicago have found temples, jewelry, art objects, and many other valuable archaeological items at Megiddo.

Joseph M. Hallman

Armaments. See Weapon.

Armani, *ahr MAH nee,* **Giorgio** *JAWR jee oh* (1934-), is a leading Italian fashion designer. He designs for both men and women. Armani's clothes have a soft, fluid silhouette that became his signature and one of the most important fashion trends of the late 1900's. Armani uses beautiful textiles to give special distinction to his clothes.

Armani was born in Piacenza, Italy. He began his career as an assistant buyer for a major Italian department store. He then worked with Italian designer Nino Cerruti in 1961. After free-lancing for a number of manufacturers, Armani introduced his first menswear collection in 1974. The collection created a sensation with a style known as the *unconstructed* jacket—a loose-fitting jacket with no lining or shoulder pads. Armani adapted his style for a line of women's clothes in 1975 when he formed his own company with Italian businessman Sergio Galeotti. To ready-to-wear clothing, Armani's company brought exceptional fabric quality, elegance, and a revolutionary emphasis on comfort and informality in tailoring. Jean L. Druesedow

Armature, *AHR muh chuhr,* is the coil of wire in which electric current is produced in an electric generator. The rotating coil in an electric motor also is called an armature. See **Electric generator; Electric motor.**

In a direct current generator, the armature is wound on an iron core. Electric current is produced in the coil when it is rotated in a magnetic field created by stationary electromagnets. In most alternating current generators, the armature coil remains stationary. Electric current is produced as a result of the changing magnetic field created by a set of rotating electromagnets.

In an electric motor, a current is passed through the armature coil, making it an electromagnet. The attraction and *repulsion* (pushing away) between the magnetized armature and stationary electromagnets in the motor cause the armature to rotate. Douglas M. Lapp

Armed forces. See **Air force; Air Force, U.S.; Army; Army, U.S.; Canada, Armed Forces of; Coast Guard, U.S.; Marine; Marine Corps, U.S.; Navy; Navy, U.S.**

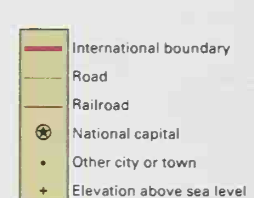
Armed Forces Day honors all branches of the armed forces of the United States. It is celebrated on the third Saturday of May with military exercises on land, at sea, and in the air. Military installations are usually open to the public on Armed Forces Day. President Harry S. Truman proclaimed Armed Forces Day, and it was first celebrated in May 1950. It replaced three separate celebrations for the Air Force, Army, and Navy. James V. Forrestal, the first secretary of defense, helped unite the armed services under the Department of Defense after World War II ended in 1945. Jack Santino

Armed Forces Staff College is part of the United States Department of Defense's National Defense University. The school is in Norfolk, Virginia. It provides military education for selected officers of the Army, Navy, Air Force, and Marine Corps. A few officers from other nations also attend the school.

The college prepares officers to serve on multiservice staffs and on military staffs of the United States and other nations. Its curriculum includes the study of national military strategy; strategic planning; command and control of combat operations under a unified command; and use of land, sea, and air forces in war. The Armed Forces Staff College was founded in 1946 by General Dwight D. Eisenhower and Admiral Chester W. Nimitz.

Critically reviewed by the Armed Forces Staff College

Armenia is a country in southwestern Asia. It is a rugged, mountainous land that lies in the Caucasus Mountain region. Yerevan is the country's capital and largest city.



Present-day Armenia and what is now eastern Turkey make up historic Armenia, the original homeland of the Armenian people. This land was conquered many times in its long history. By 1915, the Turks had driven most Armenians out of western Armenia, which became eastern Turkey.

In 1920, Russian Communists took control of eastern Armenia. This area became part of the Transcaucasian Republic of the Soviet Union in 1922. In 1936, it became a separate Soviet republic called the Armenian Soviet Socialist Republic. Armenia remained under Soviet control until 1991, when the people voted to become an independent nation.

Several million Armenians live outside Armenia. The strong national identity of Armenians worldwide helped keep the Armenian culture alive during the years of Soviet control.

Government. In 1995, the Armenian people voted to adopt a new constitution. The most powerful official in

Armenia

WORLD BOOK maps

Armenian shoppers examine produce at a local market in Yerevan, *shown here.* The country's farmers raise a variety of fruits and vegetables for such markets.

Armenia's national government is the president, who is elected by the people to a five-year term. The president appoints a prime minister. The prime minister heads a cabinet, which helps carry out government functions. Cabinet members are appointed by the president. A one-house legislature called the National Assembly makes Armenia's laws.

Armenia's main units of local government are regions, cities, and *city regions* (regions within cities). Each of these political units has a governing council, whose members are elected by the people. All Armenians 18 years old or older may vote.

Armenia's highest court is called the Court of Cassation. There are also courts of appeal for criminal, military, civil, and economic cases.

About 60,000 people serve in Armenia's armed forces. All young men must serve an 18-month term, starting at the age of 18.

Facts in brief

Capital: Yerevan.

Official language: Armenian.

Official name: Haikakan Hanrapetoutioun (Republic of Armenia).

Area: 11,506 mi² (29,800 km²). *Greatest distances*—north-south, 170 mi (275 km); east-west, 130 mi (210 km).

Elevation: *Highest*—Mount Aragats, 13,419 ft (4,090 m) above sea level. *Lowest*—Aras River at the southeastern border, 1,475 ft (450 m) above sea level.

Population: *Estimated 2002 population*—3,543,000; density, 308 per mi² (119 per km²); distribution, 67 percent urban, 33 percent rural. *1989 census*—3,304,776.

Chief products: *Agriculture*—apricots, barley, cattle, peaches, quinces, sheep, walnuts, wheat, wine grapes. *Manufacturing*—chemicals, electronics, machinery, processed food, synthetic rubber, textiles. *Mining*—copper, gold, lead, zinc.

Flag: Armenia's flag has three horizontal stripes. From top to bottom, the stripes are red, blue, and orange. See Flag (picture: Flags of Asia and the Pacific).

Money: *Basic unit*—dram. One hundred luma equal one dram.

People. About 90 percent of Armenia's people are Armenians. Kurds and Russians make up the country's largest minority ethnic groups.

Most of Armenia's people live in urban areas, in apartment buildings. Many people in smaller cities and villages live in single-family houses. Armenians place great importance on hospitality and on close family ties. Often, more than two generations of a family live together. In the cities, many women hold jobs outside the home, but they still do most of the housework and shopping.

Most people in Armenia speak the Armenian language. Armenian is unlike any other language and has its own alphabet.

Armenia was the first country in the world to make Christianity its official religion. It did so in the early 300's. Today, most Armenians belong to the Armenian Church, an Eastern Orthodox Church.

Armenians enjoy such foods as barbecued shish kebab, bean salads, a thin bread called *lavash,* and *dolma* (cabbage or grape leaves stuffed with rice and meat). Fruit juices, wine and cognac, and *tan* (a mixture of water, yogurt, and salt) are popular beverages.

Chess and backgammon are popular forms of recreation in Armenia. Yerevan has many theaters for motion pictures, concerts, and drama. It also has an opera house and a symphony hall.

Armenians enjoy such sports as basketball, tennis, and soccer. During the summer, many Armenians vacation at Lake Sevan—a popular resort area—or at summer homes in the countryside.

Armenia has a rich artistic tradition. Its people have excelled at such crafts as rug weaving and metalwork. The making of decorative carved stone monuments called *khatchkars* is a purely Armenian art form. Armenian architecture through the ages has produced beautiful stone churches, many with domed roofs. Armenia also has a highly developed tradition of religious music dating to the Middle Ages. Many Armenian craftworkers and artists carry on old traditions today.

Nearly all adults in Armenia can read and write. The government requires children to attend school from the ages of 6 to 16. A student may then attend a technical school or go on to higher education at a university or specialized institute. Armenia has a number of schools of higher education.

Land and climate. Armenia lies on the Armenian Plateau, a rugged highland that extends from the Little Caucasus Mountains southwest into Turkey. The land is broken by mountains and deep gorges. Armenia has an average altitude of 5,000 feet (1,500 meters) above sea level. The highest mountain ranges stand in central Armenia. The country's highest point, Mount Aragats, rises 13,419 feet (4,090 meters). The lowest altitudes are in the northeast and southeast.

Much of the Armenian Plateau was formed millions of years ago by volcanic activity. For this reason, most of Armenia is covered with volcanic stones. *Faults*—fractures in the earth's rocky outer shell—crisscross the plateau, and earthquakes sometimes occur in Armenia.

Armenia has about 100 mountain lakes. Lake Sevan, in the east, is the largest. It covers about 5 percent of Armenia. The country also has many small, fast-flowing rivers and streams. The longest river, the Aras, separates Armenia from Turkey on the west and from Iran on the

Robert Harding Picture Library

Armenia's rugged land includes mountains and gorges. The country lies on the Armenian Plateau and has an average altitude of 5,000 feet (1,500 meters) above sea level.

south. The streams and rivers serve as a source for irrigation and energy. A chain of hydroelectric power stations stands along the Razdan River, between Lake Sevan and Yerevan.

Most of Armenia's vegetation consists of grasses and shrubs. Some forests of beech, hornbeam, juniper, and oak are found in the northeast and southeast.

The country's climate is dry, with long cold winters and short hot summers. January temperatures usually range from 10 to 23 °F (−12 to −5 °C) and can fall below −22 °F (−30 °C). July temperatures average about 50 °F (10 °C) in the mountains and about 77 °F (25 °C) elsewhere.

Armenia receives a yearly rainfall of about 8 to 31 inches (20 to 80 centimeters), rising with elevation. The highest peaks are snow-covered all year.

Economy. Manufacturing and mining account for about two-thirds of the value of Armenia's economic production. The chief industries make chemicals, electronic products, machinery, processed food, synthetic rubber, and textiles. Armenia is a leading distiller of cognac. The country's main industrial centers are Alaverdi, Kapan, Kirovakan, Gyumri, and Yerevan. Copper is Armenia's most important mineral. Armenian mines also produce gold, lead, and zinc.

Service industries account for about a fourth of Armenia's economic production. These industries include education, health care, and government activities.

Agriculture accounts for about 10 percent of the production. Farm products include apricots, barley, peaches, potatoes, quinces, walnuts, wheat, and wine grapes. Crop production benefits from Armenia's many areas of fertile black topsoils called *chernozem* soils. The Aras River Valley is the chief farming region. Herders raise cattle and sheep on mountain slopes.

Armenia has several railways and an extensive road and highway system. But relatively few people own cars. Buses and trolleys are the main forms of transportation in most cities and towns. Yerevan has a subway. An international airport also operates at Yerevan.

About 90 newspapers are published in Armenia. The country's radio and television studios are located in Yerevan.

History. People lived in historic Armenia by 6000 B.C. The earliest societies in the region were probably tribal groups that lived by farming or raising cattle. In the 800's B.C., a coalition of several tribes formed the kingdom of Urartu. The Urartians introduced irrigation and built fortresses, palaces, and temples. In the 600's B.C., ancestors of the Armenians migrated—probably from the west—to the Armenian Plateau. They settled with the native population. In the 500's B.C., Urartu was conquered by the Medes, a people from what is now Iran.

Soon after Urartu fell to the Medes, the Medes were conquered by the Persians. Armenia was under Persian and then Greek rule for hundreds of years. But it maintained a degree of independence.

King Tigran II, who came to power in 95 B.C., built an independent Armenian empire that reached from the Caspian Sea to the Mediterranean Sea. The Romans defeated Tigran in 55 B.C., and Armenia became part of the Roman Empire.

In the early A.D. 300's, Armenia became the first nation to adopt Christianity as its state religion. The Armenian alphabet was developed in the early 400's by an Armenian cleric. In 451, Armenians under Vartan Mamikonian defended their religion against the Persians in the Battle of Avarair.

Arabs conquered Armenia in the 600's. In 884, Armenians created an independent kingdom in the northern part of the region. Seljuk Turks conquered Armenia in the mid-1000's, but Armenians established a new state in Cilicia on the Mediterranean coast. This last Armenian kingdom fell to Mameluke invaders in 1375.

Ottoman rule. By 1514, the Ottoman Empire had gained control of Armenia. The Ottomans ruled western Armenia until their defeat in World War I in 1918. Persians gained control of eastern Armenia in 1639. They ruled it until 1828, when it was annexed by Russia. During the 1800's, the growth of nationalism among Turks, Armenians, and other peoples caused conflicts.

During the late 1800's, Armenians under Ottoman rule suffered increasingly from discrimination, heavy taxation, and armed attacks. From 1894 through 1896, the Ottomans and Kurds, under Sultan Abdülhamit II, carried out a campaign to wipe out Armenians. Hundreds of thousands of Armenians were killed.

Armenia became a battleground between the Ottoman Empire and Russia during World War I (1914-1918). The Ottomans feared that the Armenians would support the Russians. In 1915, the Ottoman government deported Armenians who were living in western Armenia into the deserts of what is now Syria. About 1 million Armenians died from lack of water and starvation or were killed by Ottoman soldiers or Arabs and Kurds. A large number of survivors fled to Russian Armenia, where, in 1918, an Armenian republic was established.

Soviet rule. Conflicts resurfaced between the Armenian republic and the Ottoman Empire. Armenia's leaders reluctantly turned to Communist Russia for protection. In December 1920, eastern Armenia became a Communist republic. The Ottomans kept the rest of Armenia. In early 1922, Armenia joined Azerbaijan and

Georgia to form the Transcaucasian Republic. This republic was one of four that joined to form the Soviet Union in late 1922. In 1936, Armenia, Azerbaijan, and Georgia became separate republics of the Soviet Union.

Joseph Stalin became dictator of the Soviet Union in 1929. He ruled by terror, allowed little expression by nationalist groups, and had many political and cultural leaders killed. After Stalin's death in 1953, the Soviet Union became more tolerant of national differences. Armenia began to develop into a more modern, European-style society while preserving its ethnic culture.

Before the beginning of Soviet rule in the 1920's, most Armenians had lived in rural areas and worked as farmers or herders. Also, because the region lies on ancient trade routes, many Armenians had become merchants or traders. Under Soviet rule, Armenia became industrialized. The Soviet government built many factories and modern apartment buildings in Armenia's cities. Many rural people moved to the cities.

Nagorno-Karabakh, an *autonomous* (self-governing) region in neighboring Azerbaijan, has long been a source of dispute between Armenia and Azerbaijan. Until the late 1980's, a large majority of the people of Nagorno-Karabakh were Armenians. In 1988, large numbers of Armenians demonstrated in Yerevan and other cities, demanding that Nagorno-Karabakh be made part of Armenia. The protests soon led to fighting between Armenians and Azerbaijanis. After the fighting began, about 400,000 Armenians fled to Armenia from Azerbaijan. About 200,000 Azerbaijanis—almost all those who lived in Armenia—fled to Azerbaijan.

On Dec. 7, 1988, a severe earthquake struck Armenia. It killed about 25,000 people and destroyed much property. The destruction caused by the earthquake, along with the large number of refugees from Azerbaijan, led to a severe shortage of housing and jobs in Armenia.

Independence. In 1990, non-Communists won control of Armenia's government. The republic's legislature then declared that Armenia's laws took precedence over those of the Soviet Union. In early 1991, the Armenian legislature scheduled a referendum on independence to be held in September.

In August 1991, conservative Communist officials failed in an attempt to overthrow the Soviet Union's president, Mikhail S. Gorbachev. In the upheaval that followed, several republics declared their independence. In September, the Armenian people voted for independence from the Soviet Union. In October, Levon Ter-Petrosyan was elected president. In December, Armenia joined other former republics in an association called the Commonwealth of Independent States. The Soviet Union was formally dissolved on December 25.

During the Soviet era, the government owned most of Armenia's businesses, factories, and farmland. But in 1991, the government began to introduce elements of a free-enterprise system. By the time the Soviet Union broke up, the government had sold about three-fourths of the farmland to private owners. Through the 1990's, the government converted many other businesses to private ownership, and capitalism took root in Armenia.

Recent developments. In 1994, Armenia and Azerbaijan declared a cease-fire in the fighting over Nagorno-Karabakh. However, sporadic fighting continued, and the conflict over the territory remained unresolved.

In 1996, Levon Ter-Petrosyan was reelected president of Armenia. However, many Armenians protested that the election had been marred by fraud. In February 1998, Ter-Petrosyan resigned, and Armenia's prime minister, Robert Kocharian, became acting president. In March 1998, Kocharian was elected president.

In October 1999, gunmen entered the parliament building and assassinated Prime Minister Vazgen Sarkisyan and several other government officials. The gunmen were arrested, and Kocharian appointed replacements for the slain officials. Nancy Lubin

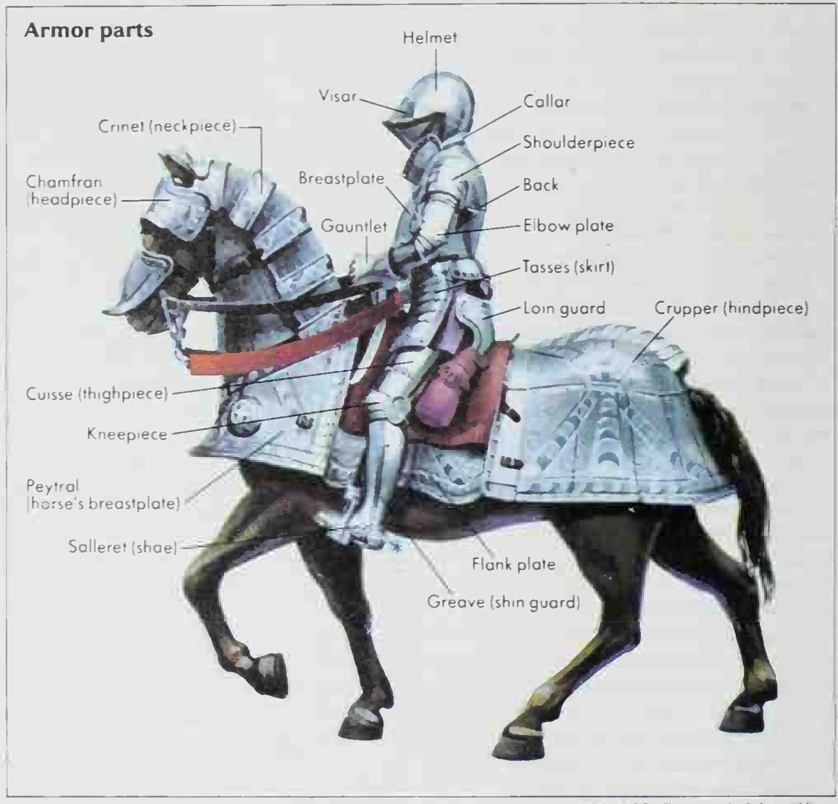
Armey, Dick (1940-), a Republican from Texas, became majority leader of the United States House of Representatives in 1995. In 1993 and 1994, he served as chairman of the House Republican Conference, the Republicans' main policymaking body in the House.

Before Armey became majority leader, he helped wage an aggressive campaign against policies of the Democratic Party. This campaign helped the Republicans win control of both houses of Congress from the Democrats in the elections of 1994. Armey became a strong supporter of free-market capitalism and an opponent of many government social programs.

Richard Keith Armey was born on July 7, 1940, in Cando, North Dakota. He earned a B.A. degree from Jamestown College in 1963 and a Ph.D. in economics from the University of Oklahoma in 1968. He was a professor of economics at North Texas State University from 1972 to 1983. Armey first won election to the House in 1984. Jackie Koszczuk

Arminius, *ahr MIHN ee uhs,* **Jacobus,** *juh KOH buhs* (1560-1609), was a Dutch theologian. He tried to liberalize severe Calvinist views on predestination, which stated that God unconditionally chooses some people to be saved and others to be damned (see **Predestination**). Arminius denied absolute predestination. He taught that predestination was based on God's knowing in advance who would believe in Jesus. But people can still resist the Holy Spirit's call to grace and even lose salvation. Thus, complete assurance of final salvation is impossible. Arminius's doctrines were called *Arminianism.*



Arminius's followers published a *Remonstrance* in 1610 that summarized his views. Orthodox Calvinists claimed that Arminianism would weaken Dutch national unity by dividing Calvinism, the national religion. A council called the Reformed Synod of Dort (1618-1619) condemned Arminianism. The doctrines still spread to England and the English colonies in America. Arminianism influenced other Protestant denominations, especially Methodism. Arminius was born on Oct. 10, 1560, in Oudewater, South Holland. Ralph W. Quere

Armor is a covering used primarily for protection in battle. Through the centuries, such materials as animal skins, bronze, and steel have been used to make armor. Until the invention of firearms, increasingly effective armor was designed to match advances in weapons. However, the use of individual armor declined when it became so heavy in order to be bulletproof that it could not be worn. Today, armor is used mainly on ships, tanks, and other military vehicles.

WORLD BOOK illustrations by Robert Addison

People have used armor to protect themselves in battle since prehistoric times. The armor worn through the centuries, *left,* was made from such materials as animal skins, bronze, and steel. In the 1400's—during the late Middle Ages—metal armor covered a soldier's entire body, as well as his horse, *above.*

In early times, primitive people wore layers of animal hides to soften blows from clubs and axes. The Assyrians and people of other early civilizations carried shields and wore helmets and body armor made chiefly of leather strengthened with bronze. The Greeks and later the Romans wore helmets, *cuirasses* (short body armor), and *greaves* (leg armor), and they carried large shields. Greek and Roman armor was constructed mainly of bronze or steel, and it served as protection against arrows, spears, and swords.

During the Middle Ages, the use of armor reached its peak. During the 1200's, *chain mail* (tiny rings of metal linked together) served as the major form of protection. Suits of chain mail covered a knight's body from head to foot and provided protection against arrows, lances, and swords. The crusaders and many other knights also wore metal helmets that covered the face.

By the 1300's, foot soldiers fought with such weapons as crossbows, longbows, maces, and axes. Arrows fired from a longbow or crossbow could pierce chain mail, and blows from an axe or a mace would crush it. As a result, *armorers* (armor makers) began to produce *plate armor* consisting of large pieces of steel. By the 1400's, suits of plate armor were designed to cover the entire body. Helmets, *gauntlets* (gloves), and shoes—all of steel—completed the outfit. Horses wore armor as well. Plate armor was highly effective, but it was extremely heavy and hot to wear. A suit of armor was also expensive, costing as much as a small farm.

Armorers were highly skilled craftsmen. Their job was to preserve lives, particularly those of leaders. After armor became a safe defense, armorers concentrated on decorating armor for tournaments and parades. *Gothic armor* produced in northern Italy and southern Germany became especially well known for its gracefulness and elegance. German *Maximilian armor* of the early 1500's was *fluted* (grooved) to give it extra strength and a glancing surface. By the mid-1500's, armor was etched or engraved with designs or scenes, and was often gilded or silvered. Later examples imitated current fashions in dress, or were exaggerated and grotesque.

Guns changed the ways of waging war and therefore the protection needed. Armor, made ever thicker and heavier to be bulletproof, became too heavy to wear. By the mid-1600's, only helmets and breastplates continued to be used.

Later developments. By the 1900's, the only armor soldiers wore was a helmet. Engineers began to work on group protection, armoring trains, ships, and other vehicles. During World War I (1914-1918), the British developed the tank. The tank became one of the most important weapons in World War II (1939-1945) and later

Police officers use armor in situations that involve armed suspects. These police officers, equipped with riot shields and bulletproof vests and helmets, are performing a training exercise.

conflicts. During the Korean War (1950-1953) and the Vietnam War (1957-1975), soldiers wore bulletproof body armor made of light, strong synthetic material.

Today, besides its use in warfare, armor is also worn by some people in their jobs. For example, police officers sometimes wear bulletproof vests and helmets and carry riot shields. Helmets are part of hockey and football players' uniforms. Karin N. Mango

Armour, Philip Danforth (1832-1901), an American businessman, was the principal founder of Armour and Company, one of the world's largest meat-packing firms. Armour pioneered the use of all parts of the slaughtered animal for commercial purposes. He later expanded his firm's operations to include household products and food processing. He also gained control of private railroad-car lines and banks. In 1892, he donated money to establish the Armour Institute of Technology in Chicago, which later merged with Lewis Institute to form the Illinois Institute of Technology. Armour was born in Stockbridge, New York. William R. Childs

Arms control is the limiting, regulating, reducing, or eliminating of a nation's armed forces and weapons. Most arms-control agreements are treaties approved by many nations.

Arms-control proposals have ranged from general and complete disarmament to forms of limited arms control. General and complete disarmament would allow nations to keep only those weapons and forces necessary to provide police services and support international peacekeeping units. No such plan has ever been adopted. Limited arms-control measures call for restrictions on the testing, production, distribution, or possession of certain types of weapons. The restrictions may ban the weapons entirely or only forbid their presence in certain areas. Nations may also limit or ban the distribution of equipment or scientific information that can be used to produce certain kinds of weapons. Some limited arms-control agreements have been approved.

Working out an arms-control agreement is a difficult process, especially if relations between the negotiating countries are unstable. Countries negotiating an agreement may be critical and suspicious of each other and therefore may tend to disagree over proposals. In addition, it is often hard to compare the military strength of powerful nations because of differences in the types and numbers of weapons. The combined strength of allied nations also makes comparisons difficult.

The current arms-control debate

The argument for arms control. Today, many nations have the ability to make "weapons of mass destruction," including chemical, biological, and nuclear weapons. The existence of such weapons has helped encourage support for arms control. People who favor arms control use the following arguments:

The overwhelming power of modern weapons exceeds any reasonable purpose. Today, one submarine can carry missiles and nuclear warheads that contain more destructive power than all the weapons used during World War II (1939-1945). The use of all existing nuclear warheads in an attack would almost certainly destroy the countries attacked. Similarly, the use of chemical or biological weapons against troops or civilian populations would cause large numbers of deaths.

The threat to use such weapons against a country might itself cause a war. A threatened country might question its ability to survive an attack. As a result, it might attack first if it feared that it was about to be attacked. Arms control is intended to reduce such fears.

Arms control reduces the need for countries to acquire nuclear weapons or increase their supply of other weapons. Arms control thus eases world tension and limits other conditions that might lead to nuclear war.

The argument against arms control. Some nations want to build or acquire sophisticated weapons because they regard them as a symbol of technological achievement, prestige, and modernness. Also, many people feel more secure if their country is militarily strong. Opponents of arms control use the following arguments:

Armed forces and weapons by themselves do not cause international disputes or tension. They merely reflect political, economic, and other kinds of disputes. These disputes must be settled before nations can agree on arms control. Nations that first try to agree on arms control raise false hopes that may cause people to oppose spending the money necessary for defense.

Arms-control agreements between an open, free society and a secret, totalitarian society are risky. The totalitarian nation often will not permit adequate inspection to assure that it is keeping its part of the agreement.

Arms control may damage a nation's military defense. Agreements may call for the destruction of some needed weapons and may also prevent the replacement or improvement of other necessary weapons systems.

History of arms control

Until the 1900's, there were only a few limited arms-control agreements. One was the Rush-Bagot Agreement of 1817 between the United States and the United Kingdom. This agreement limited each nation's armed forces along the Great Lakes. The peace treaty signed after World War I (1914-1918) disarmed Germany and limited the size of its army. In 1922, the Washington Conference led to an arms-control agreement among France,

Italy, Japan, the United Kingdom, and the United States. These nations agreed to destroy some of their battleships and ban construction of others for 10 years. At the London Naval Conference in 1930, Japan, the United Kingdom, and the United States consented to limit the size and guns of their cruisers, destroyers, and submarines. This agreement lasted only until 1936.

Agreements at the end of World War II (1939-1945) provided for the disarmament of Germany and Japan. After the war, the United Nations (UN) tried to obtain an agreement limiting arms for all nations.

In 1952, a 12-nation Disarmament Commission set up by the UN General Assembly began to meet. In 1959, it took in all UN members. In 1961, a treaty to keep Antarctica free of military weapons took effect. In 1963, the Limited Test Ban Treaty was ratified by the United States, the Soviet Union, and the United Kingdom. It prohibited testing of nuclear weapons in the atmosphere, in outer space, or underwater. A treaty often called the Outer Space Treaty, which took effect in 1967, limited military activity in outer space. That same year, 21 Latin American states signed the Treaty of Tlatelolco, which banned nuclear weapons in Latin America. Today, most Latin American countries participate in the treaty. In 1968, the UN approved the Treaty on the Non-Proliferation of Nuclear Weapons, which prohibited countries from giving nuclear weapons to other nations. It took effect in 1970.

Several more UN arms-control treaties won approval during the early 1970's. The Seabed Arms Control Treaty, which took effect in 1972, prohibited countries from putting nuclear weapons on the ocean floor more than 12 nautical miles (23 kilometers) from their coastlines. The Biological Weapons Convention, a UN treaty signed in 1972, banned the production and stockpiling of biological weapons. It went into effect in 1975.

Meetings between the Soviet Union and the United States to discuss the possibility of limiting *strategic* (long-range offensive) nuclear weapons led to two agreements in 1972. The first agreement limited each nation's defensive missile strength. The other agreement restricted U.S. and Soviet production of certain kinds of offensive nuclear weapons. Both agreements went into force in 1972. See Strategic Arms Limitation Talks.

Beginning in the late 1980's, improved relations between the United States and the Soviet Union led to a number of arms-control agreements. A U.S.-Soviet treaty that went into effect in 1988 eliminated all of the two countries' ground-launched nuclear missiles with ranges of 500 to 5,500 kilometers (310 to 3,420 miles). It also provided for the first inspection procedures on national territory to support verification.

In 1990, the United States, the Soviet Union, and 20 other nations signed a treaty to destroy large numbers of their tanks and other nonnuclear weapons in Europe. This agreement, called the Treaty on Conventional Armed Forces in Europe, went into effect in 1992.

In July 1991, U.S. President George H. W. Bush and Soviet President Mikhail Gorbachev signed the Strategic Arms Reduction Treaty, or START. This treaty, now known as START I, was designed to reduce U.S. and Soviet long-range nuclear missiles and bombers by about a third. Later in 1991, the United States and the Soviet Union stated that they would destroy many of their short-range nuclear weapons.

The collapse of the Soviet Union in late 1991 raised questions about who would be responsible for ratifying and carrying out agreements entered into by the Soviet Union. But in 1992, officials of Belarus, Kazakhstan, Russia, and Ukraine—the four former Soviet states that possessed nuclear weapons—signed an agreement upholding START I. The agreement also committed Belarus, Kazakhstan, and Ukraine to eliminating their nuclear weapons. The United States and the four former Soviet states ratified the agreement. It went into effect in 1994.

In 1993, Bush and Russian President Boris Yeltsin signed START II, a treaty to supplement START I. START II called for cutting the number of U.S. and former Soviet long-range nuclear weapons to less than half the number proposed by START I. However, START II never went into effect, due to disputes over later amendments to the agreement. In 2001, U.S. President George W. Bush and Russian President Vladimir Putin agreed to pursue further reductions in their countries' nuclear forces. The following year, they signed a treaty to reduce the U.S. and Russian nuclear forces by about two-thirds over 10 years.

In 1993, over 120 nations signed a UN-sponsored treaty banning the making, use, transfer, and stockpiling of chemical weapons. The treaty took effect in 1997.

In 1996, the UN approved the Comprehensive Nuclear Test Ban Treaty, which was designed to end the testing of nuclear weapons. To go into effect, the pact must be ratified by all countries that have *nuclear reactors* (devices for producing nuclear energy). Three of these countries—India, Pakistan, and North Korea—have not signed the treaty, and many other countries have not ratified it. However, the countries that have approved the pact are expected to abide by it even if India, Pakistan, North Korea, and other countries do not ratify it.

Since 1997, over 130 countries have signed a treaty banning the use of land mines that are designed to kill or injure soldiers. The treaty went into effect in 1999. However, some countries consider land mines to be important defensive weapons and refuse to sign the treaty.

Armstrong, Edwin Howard (1890-1954), an American electrical engineer and inventor, made important contributions to electronics and radio communication. In 1933, he introduced the *frequency modulation* (FM) broadcasting system that is still in use today. This system provided better sound reproduction and less static interference than the older *amplitude modulation* (AM) system (see Frequency modulation). Earlier, in 1918, Armstrong developed the superheterodyne radio receiver, which became widely used. In 1921, he developed the superregenerative receiver that came into use

in mobile radio and other systems. Armstrong was born on Dec. 18, 1890, in New York City. James E. Brittain

Armstrong, Lance (1971-), an American cyclist, gained international fame in 1999 when he won the Tour de France, the world's most prestigious bicycle race. He won the race again in 2000, 2001, and 2002. Greg LeMond is the only other American cyclist to win the event. Armstrong raced as a member of the United States Postal Service team. His victories capped a courageous comeback in a fight against cancer.

Armstrong was born on Sept. 18, 1971, in Plano, Texas. He began his professional cycling career in 1992 as a member of the Motorola team. In 1993, Armstrong won the World Cycling Championships, held in Oslo, Norway. He captured the Tour DuPont, the best-known bicycle race in the United States, in 1995 and 1996.

In 1996, Armstrong learned that he had testicular cancer and that the disease had spread to his abdomen, lungs, and brain. After 18 months of medical treatment that included chemotherapy and surgery, he returned to competitive cycling in 1998. Armstrong wrote a memoir called *It's Not About the Bike* (2000). Dave Nightingale

Armstrong, Louis (1901-1971), was one of the most famous and influential performers in the history of jazz. Armstrong gained recognition as the world's greatest jazz cornet and trumpet player in the 1920's and early 1930's. He also became famous as a singer with his distinctive gravelly voice.

Armstrong was born on Aug. 4, 1901, in New Orleans. He learned to play the cornet while serving a sentence for delinquency in the Home for Colored Waifs. In 1922, Armstrong left New Orleans to join King Oliver's Creole Jazz Band in Chicago. His first recorded solo appears on the band's recording of "Chimes Blues" (1923). Armstrong was coached by Lil Hardin, the band's classically trained pianist. Armstrong and Hardin were married in 1924. In that year, with Hardin's encouragement, Armstrong left Oliver to join the Fletcher Henderson band in New York City.

In 1925, Armstrong returned to Chicago. There, during the next three years, he made a series of small band recordings that rank among the masterpieces of jazz. Many of these recordings were issued under the names Hot Five and Hot Seven. They showed Armstrong's brilliant tone and tremendous range.

In the Hot Five recording of "Heebie Jeebies" (1926), Armstrong first employed *scat singing,* a form of rhythmic wordless singing. Many singers adopted the style. During this period, Armstrong switched from the cornet to the trumpet.

Starting in 1929, Armstrong appeared in musical shows, often as featured soloist with a big band. By the mid-1930's, he had become less of a jazz artist and more of a popular entertainer, on the advice of his managers. However, he retained his brilliance as a trumpeter. In 1947, Armstrong formed the first in a series of small bands called the All-Stars. As he grew older and his health declined, he played less and sang more. A new generation of fans in the 1950's and 1960's knew Armstrong mainly as an outgoing singer and entertainer. He made several hit vocal recordings, including "Hello, Dolly!" (1963) and "What a Wonderful World" (1967). Armstrong wrote an autobiography, *Satchmo: My Life in New Orleans* (1954). A selection of his writings was published as *Louis Armstrong: In His Own Words* (1999). Eddie Cook

Armstrong, Neil Alden (1930-), a United States astronaut, was the first person to set foot on the moon. On July 20, 1969, Armstrong and Buzz Aldrin landed the Apollo 11 lunar module *Eagle* on the moon. Armstrong left the module and explored the surface of the moon. Upon taking his first step onto the moon, Armstrong said: "That's one small step for a man, one giant leap for mankind." But the word *a* was lost in radio transmission.

Armstrong was born on his grandparents' farm in Auglaize County, Ohio, on Aug. 5, 1930. His family settled in Wapakoneta, Ohio, when Neil was 13 years old. A love of airplanes grew when he went for his first plane ride in a Ford Tri-Motor, a "Tin Goose," at the age of 6. From then on, he was fascinated by aviation.

In 1947, Armstrong entered Purdue University. He began studies in aeronautical engineering. But in 1949, the United States Navy called him to active duty. Armstrong became a Navy pilot and was sent to Korea in 1950, near the start of the Korean War. In Korea, he flew 78 combat missions in Navy Panther jets. In 1952, Armstrong returned to Purdue. He earned a bachelor's degree in aeronautical engineering there in 1955.

Armstrong was a civilian test pilot assigned to test the X-15 rocket airplane before becoming an astronaut in 1962. He made his first space flight in 1966 on Gemini 8 with David R. Scott. The two men performed the first successful docking of two vehicles in space—the Gemini 8 and an uninhabited Agena rocket.

Armstrong resigned from the United States astronaut program in 1970. Also in 1970, he earned a master's degree in aerospace engineering at the University of Southern California. From 1971 to 1979, Armstrong was a professor of aerospace engineering at the University of Cincinnati. In 1986, he was named vice chairman of a presidential commission investigating the breakup of the space shuttle Challenger. From 1982 to 1992, he was chairman of the board of Computing Technologies for Aviation, a company that develops software for flight scheduling. James R. Hansen

Tanks and soldiers from the British Army travel across the desert in Saudi Arabia during the Persian Gulf War in 1991. The armies of 29 countries fought in this war.

Army

Army is the branch of a nation's armed forces that is trained to fight on land. An army consists of ground troops, their weapons and equipment, and military bases. It includes infantry, armored vehicles, and artillery, plus support troops who handle transportation, medical care, and other responsibilities.

Almost every nation has an army. Armies vary greatly in size and strength, depending on several factors. The economy of a nation plays a major role because wealthy nations can afford to buy expensive weapons and pay large numbers of soldiers. Nearly all developed nations maintain armies with large numbers of tanks, armored personnel carriers, helicopters, and even ships. Less developed nations that cannot afford advanced weapons often depend on specially trained light infantry, small ground attack aircraft, and armored cars.

Potential threats also shape a nation's army. For example, Switzerland, which has few potential enemies, does not have a standing army of professional soldiers. It instead maintains a large national militia of men who can be called into service at any time. Nations with extensive foreign commitments, such as France, the United Kingdom, and the United States, need a large standing army to meet their needs outside the country.

Countries also differ in how they raise and maintain their army. Some nations use a military draft, in which certain individuals are selected for duty. Others have universal military service, which requires all qualified men and women in a certain age range to serve. Still other nations have a completely volunteer army. Today, almost all armies include women.

Most nations divide their army into a *regular army* and an *army reserve.* The regular army consists of professional soldiers. They continually receive training and are always on active duty and ready for combat. No nation, however, can afford to support a regular army large enough to meet any crisis. Even nations that rely on large regular forces generally maintain an extensive army reserve. Such a reserve, also called a *national guard* or *militia,* trains citizens for immediate active duty in an emergency. Except during training, reservists remain on inactive duty, living as civilians but prepared to respond to a call to duty.

For thousands of years, warfare consisted almost entirely of battles between armies. Often, a single land battle would decide the fate of nations and empires. Beginning in the 1600's, the importance of navies rose to equal that of land forces. In the early 1900's, military aircraft first appeared and changed warfare forever. Armies still formed the largest part of the military power of most nations. But nations began to use their armies in combination with air and naval units in *joint operations,* which involve more than one branch of the armed forces. The rise of military alliances beginning in the 1700's led to the growth of *combined* or *coalition* warfare, which involves the military forces of several nations.

Every army has a specific set of ideas, plans, and training practices that determines how it fights. For example, a nation in a mountainous or jungle region will have

Robert R. Mackey, the contributor of this article, is Professor of Military History at the United States Military Academy at West Point and a major in the United States Army.

substantially different plans and practices than an industrialized nation with an advanced highway system.

The organization of armies

How a country organizes its army depends on the nation's customs, its history, and the tasks it expects the army to accomplish. But there is a general similarity in the organization of armies throughout the world.

The largest units of some armies are called *army groups* and may have several hundred thousand soldiers. Army groups usually consist of several organizations themselves known as *armies.* Each army is made up of several *corps* (pronounced *kawrz* or *kohrz*). A corps (pronounced *kawr* or *kohr*) normally has from 50,000 to 100,000 soldiers. A corps consists of two or more *divisions* and any necessary support troops.

The division is the basic fighting unit of many armies. Divisions include such combat troops as infantry, armored forces, and artillery; and engineers, who are sometimes considered as combat troops. Divisions also have support troops who handle transportation, medical care, and other responsibilities. Divisions usually are identified according to their equipment, training, and function. Types of divisions include infantry, mechanized, armored, and airborne divisions.

The size of a division varies from about 10,000 to 18,000 soldiers. Most divisions have three or more *brigades* of roughly equal size, and each brigade has three to five *battalions.* The battalion, a combat unit of 500 to 800 soldiers, is further divided into groups of 100 to 200 soldiers. Infantry and armored units of this size are called *companies.* Artillery groups are known as *batteries,* and groups of *cavalry* (highly mobile forces used for scouting and surprise attacks) are called *troops.*

The role of armies

In war, a nation uses its army to conquer enemy territory and to defend itself from attack. In peacetime, an army can help prevent war. It also aids civilians in certain emergencies.

Attack. A nation may seek to take over territory held by an enemy by conducting offensive operations. The attacker's tanks and other armored vehicles invade the enemy's territory, with planes and artillery supporting the advance. Other planes drop airborne troops behind enemy lines, and helicopters carry in specially trained soldiers, sometimes called *special forces* or *commandos,* to seize certain key positions. Later, mechanized infantry sweeps in and occupies the conquered territory.

Defense. An army is trained for both offensive and defensive combat operations. But some units may be assigned to fight only in case of an enemy attack. In the past, fortifications along borders formed the main line of defense for many countries. But modern armies do not rely nearly as much on fortifications, which can often be bypassed with airborne assaults or by the combined action of land, sea, and air forces.

Prevention of war. A powerful nation may sometimes station troops in politically troubled regions or in areas threatened by attack. Such a show of military strength may help prevent war. In 1991, for example, French and Belgian troops went to Zaire—now Congo (Kinshasa)—to restore order after Zairian soldiers rioted.

The development of *tactical nuclear weapons* in the 1950's gave armies an important defensive strategy. These weapons are designed to be used in areas where a conventional war is being fought. An army that massed its men and equipment was vulnerable to a nuclear attack. The fear of such an attack could prevent a nation from invading an enemy. This idea, known as *deterrence,* was used by the Soviet Union and Western nations from the end of World War II in 1945 to the late 1980's, a period of hostility known as the Cold War.

Internal security and civilian aid. Armies may be used by a nation for roles other than combat. In some countries, armies serve as an internal police force. In others, regular or reserve forces may serve in a multitude of roles that include disaster relief, humanitarian

Embassy of Pakistan

Soldiers from Pakistan's army aim a mortar before firing. Mortars, which fire shells in a high arc, can reach targets that are protected by hills or other obstacles.

Thierry Campion, Gamma/Liaison

Armies wear protective clothing to prevent injury from chemical, biological, or radiological weapons. These soldiers from the French Army are outfitted for a chemical attack.

Rick Rosen, SABA

A country may use its army to maintain order within its own borders during periods of internal unrest. This Israeli soldier is checking the identification of civilians in Jerusalem.

aid to foreign nations, and peacekeeping functions. They may respond to major disasters, such as forest fires or hurricanes, to provide emergency medical aid and food and water distribution, or to prevent looting.

The world's major armies

An army's ranking among the armies of the world is based on its overall fighting strength. In general, fighting strength depends on the number of troops on active duty. However, an army's size does not necessarily reflect its actual strength. Well-trained soldiers and modern weapons are also important. A small army with tactical nuclear weapons may have greater striking power than a large army with outdated weapons.

The world's major armies include those of China, India, North Korea, Russia, the United States, France, and the United Kingdom. All of these armies except India's and North Korea's have tactical nuclear weapons. However, both India and North Korea have the capability to produce such weapons.

The Chinese Army has about 1 $\frac{1}{2}$ million troops on active duty. Many of the forces are assigned to defensive positions near the Russian border in northeastern China. The Chinese Army has about 1 million people in its reserve and armed militia. China uses a military draft.

The Indian Army has about 1,100,000 men on active duty, about 300,000 in the reserve, and about 40,000 in the Territorial Army. Only a few hundred women serve in the Indian Army, many as doctors and nurses. All members of India's Army are volunteers.

The North Korean Army has about 950,000 troops on active duty and about 600,000 in the reserve. Men from the ages of 20 to 25 are drafted to serve for five to eight years. After service, they serve part-time in local militias until the age of 40 and then in the Red Guard until the age of 60. Women may join the army on a volunteer basis.

The Russian army, officially called the Ground Forces of the Russian Federation, has about 320,000 troops on active duty. Many troops are posted along Russia's border with China. Russia began organizing its army in 1992, following the breakup of the Soviet Union in 1991. The Russian army has small forces in the former Soviet republics of Georgia, Moldova, and Tajikistan. The army has both volunteers and draftees. After 18 months of active duty, Russian soldiers serve in the reserve until the age of 50.

The United States Army has about 480,000 troops on active duty and about 560,000 in the reserve and National Guard. Army troops are stationed in the United States, Western Europe, Japan, South Korea, and parts of Latin America. All members of the United States Army are volunteers. See **Army, United States; National Guard.**

The French Army has about 150,000 members on active duty and 240,000 in the reserve. French troops are stationed in Western Europe, several African countries, and in France's overseas territories. The French Army has both volunteers and draftees.

The British Army has about 115,000 troops on active duty, about 175,000 people in the reserve, and about 40,000 members of the territorial defense force. British troops are stationed in Germany, Northern Ireland, and many other parts of the world. All members of the British Army are volunteers.

Other major armies include those of Egypt, Iran, Iraq, Myanmar, Pakistan, South Korea, Turkey, and Vietnam. Each of these armies has 300,000 or more troops on active duty. The armies have purchased weapons and equipment from the world's major powers. None has tactical nuclear weapons, though Pakistan has the capability to produce them.

History

Ancient armies developed as civilizations grew in the valleys of the Tigris and Euphrates rivers in Asia, and in the Nile Valley of Africa. As early as 3200 B.C., the Babylonians had built a regular army of spear throwers and archers. About 2500 B.C., the Sumerians used the first war chariots. Small wild asses and, later, horses drew these chariots. By the 700's B.C., the Assyrians had organized armies that were equipped with spears and battering rams.

In the 600's B.C., the ancient Greeks introduced the *phalanx,* which was probably the first important tactical formation in history. In this formation, soldiers with spears and heavy armor stood from 4 to 50 rows deep in a solid rectangle. The phalanx was primarily a defensive formation. It could withstand the shock of a cavalry charge, but it could neither move rapidly nor attack across rough ground.

The mightiest conqueror of the period was Cyrus the Great of Persia. During the mid-500's B.C., Cyrus extended the Persian Empire to include most of southwestern Asia. In the 300's B.C., Alexander the Great of Macedonia, the next world conqueror, organized the first known military supply system.

The ancient Romans developed the next great tactical formation. During the early 300's B.C., they devised the *legion.* This rectangular formation had greater flexibility than the phalanx. It consisted of three lines of small phalanxes called *maniples* or, later, *cohorts.* The Romans conquered Carthage in 146 B.C. and built a great empire overseas. They were also skilled military engineers. The armies of the Roman general Julius Caesar built roads,

bridges, and forts in much of Europe. See **Legion**.

China's civilization grew up in isolation from the empires of Europe and western Asia. The Chinese had knowledge of gunpowder long before the A.D. 1300's, when Europeans began to use it in guns. But gunpowder did not become an important weapon of war for the Chinese because they did not use it in artillery, except possibly in rockets.

Armies in the Middle Ages. After the Roman Empire collapsed in the A.D. 400's, Europe had no large regular armies for several centuries. All able-bodied free men in the tribes that overran the empire were warriors. The tradition of a militia developed at this time (see **Militia**).

During the Middle Ages, the basis of Western Europe's society was a military relationship. A king ruled this society and was, in turn, supported by nobles. These nobles, who were trained as knights, ruled their own estates through a form of government called *feudalism*. Under this system, the nobles had political, economic, judicial, and military power. The lower classes, known as *serfs* or *peasants*, labored on the estates. The knights used the wealth provided by the serfs' labor to arm and equip themselves and their loyal soldiers, who were called *men-at-arms*. A knight's equipment included broadswords, lances, and armor, and it was expensive. The entire agricultural output of a knight's holdings for several years could only pay for a single warrior's armor, horses, and weapons. Due to this expense, the armies of the Middle Ages were small.

The cost of medieval armies led some rulers to turn to *mercenaries* (hired soldiers) to fight for their nations. Some mercenaries specialized in siege weaponry, such as the stone-throwing weapons called *catapults*, while others used crossbows or long spears known as *pikes*. Among the best-known mercenaries of the late Middle Ages were the Swiss pikemen. They would form large phalanxes to prevent heavily armored, mounted knights from overrunning them. The Swiss mercenaries, along with hired soldiers from England, Germany, and Italy, formed groups called *companies*. The company still forms the basic unit of most armies.

During the 1300's, the Ottoman Empire, which ruled what are now Turkey, the Middle East, Greece, and most of southeastern Europe, established the first full-time professional national army since the Roman Empire. These soldiers, known as Janissaries, were mostly slave soldiers taken from the Balkan provinces. They were much feared on the battlefield because they were loyal only to the sultan, who ruled the Ottoman Empire, and to their fellow Janissaries.

Western European nations copied the Ottoman example of a permanent army. By 1500, most major European nations had a permanent army, usually called the Royal Army or King's Army. Some nations, such as the independent states in Germany, developed the first permanent *quartermaster* organizations to find quarters and food for their armies.

Gunpowder had a dramatic impact on the organization and tactics of armies, and it played a major role in ending feudalism. Castles built by nobles could not stand up to bombardment by cannons. Rulers who could afford gunpowder-based artillery became much more powerful. The nobles lost their military function because armies of commoners with muskets could shoot them off their horses.

The rise of modern armies. By the late 1600's, infantry armed with bayonets mounted on muskets could defend themselves against cavalry charges. They did not have to rely on troops armed with pikes. Three rows of soldiers stood in ranks, shoulder to shoulder, in a formation called *the line*. A line of infantry could fire many shots at the same time at close range.

The obligation of all men to serve in wartime had disappeared almost everywhere by the early 1600's. But Sweden kept this custom throughout the Middle Ages, and King Gustavus Adolphus used a military draft to recruit troops for the Thirty Years' War (1618-1648). He gave his army greater mobility by equipping it with lighter weapons and increased firepower. His force is sometimes called the first modern army. See **Gustavus Adolphus; Thirty Years' War**.

During the 1700's, most governments continued to build their armies by recruiting volunteers, especially among the poor and unemployed. Armies became pro-

Napoleon on the Battlefield at Eylau (1808), an oil painting on canvas by Antoine-Jean Gros; Louvre, Paris (SCALA/Art Resource)

Napoleon I was one of history's greatest military leaders. This painting depicts Napoleon commanding French cavalry and infantry troops in 1807 during the Battle of Eylau near what is now the Russian city of Kaliningrad.

fessional groups of well-trained foot soldiers supported by artillery and cavalry. Most countries followed certain rules in warfare. Campaigns took place only in good weather. The troops went into quarters in winter and did not fight again until spring. They tried to gain a favorable position before they attacked the enemy. Commanders who were caught in a poor position often withdrew instead of fighting to the finish.

In the mid-1700's, Frederick the Great of Prussia introduced greater mobility to warfare. When his enemies outnumbered him, he struck quickly and unexpectedly. Frederick was forced to fight wars on several fronts at the same time. He moved rapidly to attack a single army before it could unite with others and attack his forces.

The French government adopted a military draft system in 1793. Napoleon I drafted huge armies for his conquests. He divided his armies into divisions that marched separately but joined to fight. Napoleon often massed all his heavy guns together into a *grande batterie* (big battery). He poured a tremendous amount of fire into one point in the enemy's lines, then sent forward his heavy formations of cavalry and infantry at that point. To defeat him, Napoleon's enemies had to adopt draft systems and develop national armies.

The growth in the size of armies made necessary an organization to control troops from a distance. Only a military genius such as Napoleon could personally direct so many military units in the field. From 1840 on, railroads began to spread across Europe. The Prussians realized that they could move armies much more quickly by rail, and that this made possible more accurate long-range planning. Gerhard von Scharnhorst of the Prussian Army developed the modern general staff that planned military operations.

During the 1800's, the Industrial Revolution, a period of rapid industrialization and technological advances, dramatically changed the size and strength of armies. Mass production enabled armies to equip more soldiers than ever before. Technology improved weapons and helped provide such supplies as canned food and rifles. As technology changed, so did the way armies were organized and how they fought.

Armies in the two world wars. When World War I began in 1914, the machine gun and artillery became the dominant weapons on the battlefield. The use of these weapons made free movement impossible on the Western Front, where the United Kingdom and France battled Germany. Both sides adopted trench warfare. Infantry dug in to hold their positions when they could not advance against the enemy. Railroads carried millions of soldiers to the fighting fronts. Motor trucks hauled supplies from railroads to the front lines. See **World War I.**

Field commanders tried to end trench warfare and regain tactical mobility. They shelled and bombed enemy lines, and followed with mass bayonet attacks. Sometimes they used poison gas against enemy lines. But most assaults—even those that used poison gas—failed to break through enemy lines during more than three years of intense fighting. The trenches of the Western Front repelled almost all attacks. Army commanders found a solution, but they used it improperly and too late. The United Kingdom built an armored tracked vehicle with a gasoline engine and created the first military tank. Tanks soon replaced horse cavalry. During World War I, airplanes were used for the first time in support of ground fighting. See **Tank; Air force** (World War I).

In World War II (1939-1945), tanks and airplanes restored mobility to warfare. In the war, the Allies, who included Canada, the Soviet Union, the United Kingdom, and the United States, fought the Axis powers, who included Germany and Japan. The Germans developed a type of warfare called *blitzkrieg* (lightning war). Tanks and bombers blasted great holes in enemy defenses. Then infantry poured through the gaps and carried the war deep into enemy territory. See **World War II** (The invasion of Poland).

World War II also saw the first use of armies in large-scale airborne operations. The Germans launched the first successful paratroop invasion in May 1941, when they seized the island of Crete. The largest airborne operation took place in September 1944, when three divisions of Allied paratroops dropped behind the German lines in an unsuccessful attempt to capture bridges across the Rhine River. The largest combined land, sea, and air attack in history occurred on June 6, 1944, when Allied armies landed in Normandy, in northern France.

During World War II, armies brought the military art of *logistics* (supply and services) to a high point of development. They organized huge commands that provided food, clothing, fuel, ammunition, weapons, supplies, and transportation for combat troops. The Allied victory in World War II resulted partly from superiority in logistics and in civilian industrial production. See **Logistics.**

Armies in the nuclear age. World War II ended shortly after United States warplanes dropped atomic bombs on two Japanese cities, Hiroshima and Nagasaki. Development of the atomic bomb marked the beginning of the nuclear age.

The earliest nuclear warheads could be delivered only by bomber planes flying at high altitudes. Such a delivery could not be used on the battlefield and could be considered only for *strategic targets*—that is, facilities that supported the war effort, such as weapons factories and transportation systems. By the 1950's, armies had developed nuclear cannons and missiles. These weapons changed the thinking of many experts about the tactical use of nuclear weapons. They could launch nuclear warheads at a large body of troops, a supply dump, or any other target within the weapons' range.

Since World War II, the fear of starting a nuclear war has helped prevent major armies from using nuclear weapons. As a result, only conventional weapons have been used in wars fought during the nuclear age. The first major conflict was the Korean War, which began in 1950. Large armies did most of the fighting in this war. See **Korean War.**

Armies have continued to use conventional tactics and weapons in war. For example, the U.S. Army relied heavily on conventional warfare tactics during its involvement in the Vietnam War, from 1965 to 1973. At the time, these tactics were considered the most effective way to fight Communist guerrillas in the jungles of Vietnam. However, Vietnamese guerrillas avoided major battles in the open, where heavy U.S. firepower could be decisive. They relied on surprise and mobility instead (see **Vietnam War**). Arab and Israeli forces fought wars with conventional weapons in 1956, 1967, and 1973. The tactics used by both sides resembled those of World

War II, in which aircraft and tanks spearheaded attacks and were followed into battle by infantry.

Since the mid-1970's, armies of developed nations have tended to fight brief, intense wars that usually decide a conflict quickly. Advances in computer technology and other electronics have had a massive impact on armies. Today, many armies have access to instant satellite photographs, real-time images of battlefields, and worldwide communications with political and military leaders. Armies have begun to concentrate on *strategic mobility,* the ability to quickly move troops, supplies, and equipment anywhere on short notice. This can be done using fast troop transport ships and large, troop-carrying jet airplanes. For example, during Operation Desert Storm in 1990, the United States deployed nearly 200,000 troops and their equipment to Saudi Arabia in only two months. Technology will continue to advance as time passes, and armies will likely change with each new development. Robert R. Mackey

Army, Department of the, is one of the three military departments within the Department of Defense of the United States government. It serves as headquarters of the U.S. Army, and is located in Washington, D.C. It organizes, trains, and equips land forces to support the national and international policies of the United States.

The *secretary of the Army* heads the department, under the supervision of the secretary of defense, and ranks equally with the secretaries of the Air Force and the Navy. This official's principal civilian aides include an undersecretary and five assistant secretaries.

The *chief of staff of the United States Army* serves as the main military adviser of the secretary and supervises all members and organizations of the Army. The chief of staff is assisted by the vice chief of staff and the Army General Staff. This staff includes the director of the Army staff and deputy chiefs of staff for intelligence, logistics, military operations and plans, and personnel.

Congress established the Department of War in 1789 as an executive agency. In 1903, Congress approved the adoption of a general staff system for the Army. Congress set up the National Military Establishment (NME) with a secretary of defense in 1947. At that time, the Department of War was renamed the Department of the Army and made part of the NME. In 1949, Congress replaced the NME with the Department of Defense. The Department of the Army came under the authority of the Department of Defense.

Grant Compton for *Business Week*

The United States Army is the oldest branch of the nation's armed services. The soldiers pictured above wear uniforms representing major wars fought by the Army. Those in back represent, *right to left,* the Revolutionary War, the War of 1812, the Civil War (Union Army), the Spanish-American War, World War I, World War II, and the Korean War. The soldier in front represents the Vietnam War. Army personnel also played an important role in the Persian Gulf War. The insigne worn on officers' caps, *right,* is patterned after the United States coat of arms.

United States Army

Army, United States, is the branch of the armed services responsible for military land operations. The Army must be prepared to use swift, forceful action to overcome any enemy that might threaten the United States or its interests in other parts of the world. It also helps train the military forces of many friendly countries and supplies them with equipment.

The Army is often called upon to help in disasters such as epidemics, floods, forest fires, and storms. It coordinates the disaster-relief activities of the armed services. It locates and marks civil defense shelters. In addition, the Army constructs and operates a large number of public works, including flood control projects. It also improves inland waterways and harbors.

The Army is the oldest branch of the nation's armed services. It dates back to June 14, 1775, when the Continental Congress created the Continental Army. Army history includes the deeds of such military leaders as George Washington, Ulysses S. Grant, John J. Pershing, George C. Marshall, and Douglas MacArthur, as well as the heroism of countless soldiers. It is also a story of changes brought about by science, inventions, and discoveries. Its weapons have grown from muzzle-loading muskets to atomic bursts delivered by guns and missiles. Army transport has changed from horses and wagons to trucks and aircraft. The radio, telegraph, and television revolutionized communications. The use of aircraft and airborne troops added new strength on the battlefield.

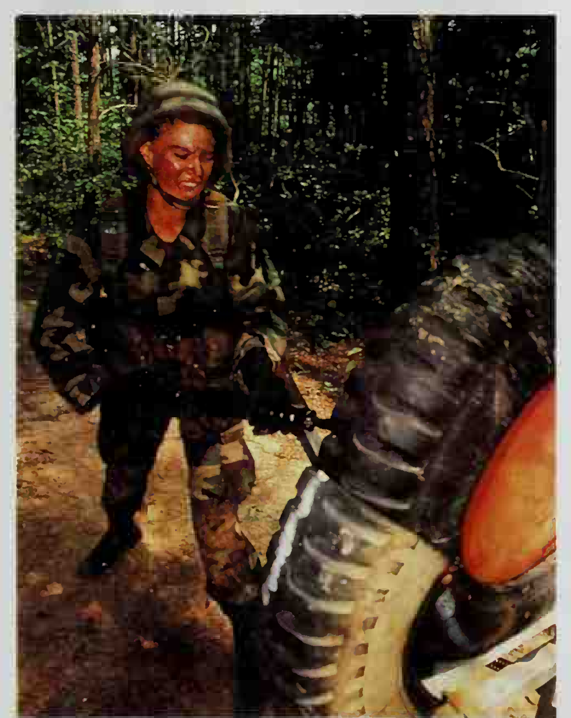
The U.S. Army operates under the Department of the Army. Army strength may vary according to the nation's worldwide and domestic needs. Today, the Army has about 480,000 men and women on active duty throughout the world. About 560,000 people serve in the U.S. Army Reserve and National Guard. About 220,000 U.S. citizens serve as civilian employees in the U.S. Army.

The official Army flag colors are blue, white, and red, with yellow fringes. The flag carries 172 streamers. Each streamer represents a battle or campaign fought by the Army. In all wars that have involved the United States, about 500,000 soldiers have died in battle. About 1,200,000 soldiers have been wounded in battle.

Life in the Army

Training a soldier. After entering the Army, trainees undergo basic training at various Army training centers. There, trainees learn a number of fundamental military skills, such as marksmanship, drill and ceremony, first aid, and land navigation. Trainees also undergo intensive physical training and are taught to act as part of a disciplined team.

After basic training, most soldiers attend a school to learn the techniques of the *military occupational specialty* (line of work) that they agreed to perform when they enlisted. These schools are located on military posts throughout the country. In school, soldiers may learn to repair a truck, rifle, or missile. They may learn to program a computer or to be a military police officer. Some schools require only a few weeks of training. Other schools give technical training that requires several months.



Enlisted women receive basic training at Fort Jackson, S.C. Then they attend specialized Army schools or receive on-the-job training at various Army posts.

Soldiers may become eligible for other schools throughout their term of service. *Noncommissioned officers* (corporals and sergeants) who are making a ca-

reer of Army service receive continued training through a special educational system.

Training an officer. To become a United States Army officer, men and women may follow one of several paths: (1) the United States Military Academy at West Point, (2) Reserve Officers Training Corps (ROTC) at many universities and colleges, (3) officer candidate schools conducted by the United States Army and by state national guards, and (4) direct commissions to civilians with special skills in such professions as law and medicine.

All Army officers receive basic and advanced training in their assigned branches. They then attend the Combined Arms and Services Staff School at Fort Leavenworth, Kansas. There they learn to be *staff officers,* able to administer the day-to-day operations of the Army. The United States Army Command and General Staff College, also at Fort Leavenworth, teaches officers how to use the various units of the Army as a team. The Army War College at Carlisle Barracks, Pennsylvania, prepares officers for senior command and staff positions.

Warrant officers rank higher than noncommissioned officers and lower than commissioned officers. They work in such specialized fields as data processing, electronics, and law enforcement. Most warrant officers are former enlisted men and women who became experts in their specialty and applied for a warrant from the secretary of the Army.

A typical day for soldiers depends on their assignments. Soldiers assigned to a unit develop the skills that they learned in basic and advanced training. They train with their unit and function as team members. They also share in tasks of maintaining the military community, such as housekeeping details and guard duty. They may participate in a sports program and use educational facilities provided by the Army. The squad leader, a noncommissioned officer, guides soldiers in their normal routine. The food service manager supervises the cooking. The supply sergeant cares for and issues clothing and equipment. The unit commander is responsible for formulating and supervising unit training.

The normal daily routine begins early on weekdays and ends by 5 p.m. Soldiers' evenings and weekends are their own, except when they are on field training exercises. During these exercises, or "practice wars," soldiers sometimes cannot eat a normal meal because of maneuver requirements. Then they receive packets of highly concentrated food that provides the nourishment they need in easy-to-carry form.

Careers in the Army offer security, honor, and opportunities for travel to many parts of the world. But soldiers must make sacrifices, because they must go wherever the Army assigns them. The Army has more than 600 jobs that require special skill or experience. A man or woman who enlists has a choice of careers, and can often use skill or training gained in civilian life. Professional men and women, such as doctors and lawyers, may receive direct commissions. Soldiers who have leadership abilities usually become noncommissioned officers. Soldiers who demonstrate high technical ability may become warrant officers. Army training often prepares a person for a civilian job later.

Applicants for enlistment must be at least 17 years of age and not older than 35. In addition, applicants must be able to pass the Army's physical examination and written examinations. Enlistments range from two to six years.

Enlisted personnel receive pay increases with each promotion, and extra pay according to *longevity* (length of service) and for some overseas duty. The Army pays extra amounts for *quarters* (housing) and *subsistence* (food). Soldiers earn 30 days' *leave* (vacation) every year. They also are entitled to free medical care. In certain areas overseas, soldiers receive *station allowances* to cover the increased cost of living. The Army also grants extra pay to various specialists and to soldiers who serve in combat or perform hazardous duty, such as demolition work. Army personnel may retire with half pay after 20 years' service, or with higher pay after 21 to 30 years.

More than 90 percent of the Army's occupational specialties are open to women. Women may serve in all units and positions except those whose mission is to engage in direct combat. These units and positions include infantry, armor, cannon artillery, short-range air defense, combat engineering, and combat aviation. Women soldiers now make up 11 percent of the Regular Army, 20 percent of the Army Reserve, and 7 percent of the Army National Guard.

Weapons and equipment of the Army

Combat units of the Army consist of soldiers trained and equipped to fight enemy forces. Infantry, artillery, armored units, Army aviation, and various specialized units are called the *combat arms* because they do the direct fighting. Other units, called the *combat support* and *combat service support,* aid the combat arms.

Infantry is the Army's largest arm. Infantrymen must seize, occupy, and defend land areas. They bear the heaviest share of close combat. Infantrymen throw grenades and fire rifles, machine guns, mortars, pistols, flame throwers, and various types of rockets and missiles. They enter battle on foot or by helicopter, parachute, or infantry fighting vehicle.

Artillery provides the firepower necessary for a heavy and successful attack by infantry or armored units. It protects troops holding defensive positions, and can neutralize enemy fire. Artillery units include *field artillery, support artillery,* and *air defense artillery.*

Artillery travels by heavy trucks, helicopters, or other means. Its weapons include the Army's heaviest howitzers and guns. The highly mobile howitzers can fire to a maximum range of about 68,200 feet (20,800 meters). Certain rocket-fired weapons have an even greater range. Some artillery weapons can fire both nuclear and conventional shells. See **Artillery**.

Armor in the Army usually means tanks and other armored vehicles. The Army uses M-60 Main Battle tanks and M-1 Main Battle tanks. The M-60 tank has a 105-mm gun. The M-1 tank has either a 105-mm gun or a 120-mm gun. The M-551 Armored Reconnaissance Airborne Assault Vehicle (Sheridan) is a light, air-transportable, missile-firing vehicle. The Army's armored units can move swiftly and advance deep into enemy territory. They also have strong firepower. See Tank.

Army aviation bolsters the Army's battlefield mobility. Army aircraft can spot enemy targets for artillery units. They provide rapid transportation to and from the

front lines. They lay communication wires and take aerial photographs. In addition, Army aircraft transport troops and supplies, and rush wounded soldiers to hospitals that are located in the rear areas.

Army aviators fly airplanes and helicopters. Airplanes are used for surveillance, observation, and command transport. Helicopters are classified as scout, utility, lift, or attack types. Attack helicopters are more mobile than airplanes and can rapidly attack targets throughout an area of operations.

The Army classifies its aircraft by letters and numbers. Thus, the UH-1H is a utility aircraft (U), a helicopter (H), first model (1), and eighth series (H). Other symbols used to indicate the type or purpose of the aircraft include: *V,* short take-off and landing; *C,* cargo transport; *O,* observation; *T,* training; and *X,* research. The Army traditionally names its aircraft after Indian tribes.

Special units. The Army has several kinds of specialized units. These include Special Forces and Rangers.

Special Forces, popularly known as *Green Berets,* are trained in various specialized operations. An important peacetime activity is helping other governments train forces that can oppose guerrillas and other rebel groups. Special forces are also trained to take part in raiding operations, antiterrorist actions, and *reconnaissance* (information gathering).

Special Forces personnel are organized into groups. Each group has responsibility for a specific region of the world. The group's members learn about the languages, customs, and cultures of the region. This training enables them to operate deep behind enemy lines.

Rangers are specialized units that can move quickly to any area of the world and that are prepared to strike by land, sea, or air. Ranger units are trained to make surprise raids behind enemy lines and to participate in other similarly daring operations. The Army has three Ranger Battalions.

Missiles. The Army's arsenal includes both free rockets and guided missiles. *Rockets* provide fire support for troops on the battlefield. Some rockets can be equipped with nuclear warheads. *Guided missiles* may be fired from ground to ground in support of troops. These missiles also can be fired from ground to air to destroy enemy aircraft. Surface-to-surface missiles include the Pershing II, which has a range of 1,100 miles (1,800 kilometers). The Army's air defense guided missiles, such as the Patriot, the Hawk, and the Chaparral, can track down and destroy enemy aircraft. See **Guided missile; Rocket.**

Communications and observation. Various types of electronic equipment are used to send and receive messages. Electronic "eyes and ears" enable the Army to survey the battlefield day and night in all kinds of weather. The Army uses portable radar sets to detect troop movements in darkness. Remote-controlled drone aircraft carry cameras, infrared devices, and radar to spot enemy positions. Electronic computers prepare weather reports, using information radioed from balloon-borne instruments.

Transportation by various types of vehicles gives the Army mobility. These include passenger and cargo vehicles, helicopters, rail equipment, watercraft, amphibious vehicles, and air cushion vehicles.

Engineers of the Army build bridges, repair roads, and construct landing strips, mine fields, and fortifications. These units must often work under direct enemy fire. Their equipment includes bulldozers, mine-clearing vehicles, and a scissors-type bridge, which is pushed into place by a tank or other tracked vehicle and extended to cross a stream or ravine. To cross rivers, the engineers also use floating bridges, inflatable assault boats, and aluminum rafts.

Equipment can be delivered to Army engineers by aircraft, or it can be dropped by parachute. Air-dropped equipment includes cranes, tractors, air compressors, and dump trucks.

Logistic units package and move supplies by air, bulk containers, and pipelines. To save time and space,

U.S. Army

The U.S. Army Special Forces is an elite unit trained to carry out daring operations. Members of the Special Forces are popularly known as *Green Berets,* though their berets may be other colors. In this picture, a Special Forces staff sergeant, *left,* provides mortar training to troops.

U.S. Army

Video screens and computers are used at an Army training center to study the action of a military exercise.

U.S. Army

An Army *Chinook* helicopter can transport jeeps, trucks, artillery, and supplies to remote military outposts.

food for combat troops is *dehydrated* (dried) and prepackaged in airtight containers, then pasteurized by irradiation to kill organisms that might cause spoilage. Soldiers can add hot water to these foods to make them edible. Special clothing developed by the Army includes protective armored vests, rubber-coated fabric clothing for handlers of missile fuels, and cold-weather clothing and boots for arctic wear. Soldiers also have special uniforms for use in desert and jungle regions.

Chemical equipment provides defense against *chemical agents* (gas), *biological agents* (germs), and the effects of radiation. Other chemical equipment includes smoke-generating devices to conceal troop movements and flame throwers to attack fortifications. Special chemical instruments detect contamination. The Army uses such equipment as protective gas masks, airtight clothing, and first-aid kits to counteract the effects of chemical, biological, or radiological warfare.

Organization of the Army

In peacetime, the U.S. Army is made up of men and women who have volunteered for service in the Regular Army, the Army Reserve, and the National Guard. Regular Army personnel are professional soldiers and are always on active duty. The Army Reserve and National Guard train citizens for immediate active duty in an emergency. Except during training, however, most members of these reserve forces remain on inactive duty. The *Active Army* consists of the Regular Army, as well as any personnel in the National Guard and the Army Reserve on active duty. In time of war or emergency, Congress may draft civilians, and the President may call to active duty members of the Army Reserve and the National Guard.

The United States Army operates under the Department of the Army, which is a part of the Department of Defense. The Army consists of a headquarters and several commands.

Photri

M-2 Bradley infantry fighting vehicles, such as the one shown here, transport soldiers onto battlefields.

Army levels of command

Unit and approximate strength	Rank of leader	Organizational elements of each unit
Theater operations *	General	Headquarters, two or more corps, support troops.
Corps *	Lieutenant general	Headquarters, two or more divisions, support troops.
Division Airborne 13,250 Air Assault 15,700 Armored 17,300 Infantry (Mech.) 17,900 Light infantry 11,500	Major general	All divisions: headquarters and headquarters company, military police company, aviation brigade, engineer brigade (except in light divisions), division artillery, two or more brigade headquarters, cavalry element, signal battalion, and support command. May have up to 15 combat battalions (air assault, airborne infantry, armor infantry, light infantry, and mechanized infantry).
Brigade 3,000-4,000	Colonel	Headquarters, varying numbers of battalions and support troops.
Battalion 300-1,000	Lieutenant colonel	Headquarters, two or more companies or detachments.
Company and battery 60-190	Captain	Headquarters, two or more platoons.
Platoon 16-44	Lieutenant	Three or four squads.
Squad 10	Staff sergeant	Smallest unit.

*Strength varies to meet situation.

Army headquarters are in Washington, D.C. The secretary of the Army, a civilian appointed by the president, heads the Army organization. The chief of staff of the U.S. Army serves as the principal military adviser to the secretary. The Army chief of staff also represents the Army on the Joint Chiefs of Staff.

The Army headquarters include the Army Secretariat and the Army Staff. The secretariat consists of agencies that report directly to the secretary of the Army. The Army Staff consists of agencies that report to the secretary of the Army through the chief of staff. The secretariat and the Army Staff provide professional advice and administrative and technical assistance to the Office of the Secretary of the Army. See **Army, Department of the; Joint Chiefs of Staff.**

The Forces Command, with headquarters at Fort McPherson, Georgia, is responsible for the combat readiness of the Army's active and reserve forces in the United States, Puerto Rico, and the U.S. Virgin Islands. The command directs these forces and supervises their combat training. In addition, it commands the Third U.S. Army, which has responsibilities in Southwest Asia and parts of Africa.

Forces Command executes its responsibilities for the Army National Guard and the Army Reserve, and for the land defense of the continental United States, through two armies. These armies are called the *CONUS Armies,* because they are headquartered in the *con*tinental *U*nited *S*tates. The two armies and their headquarters are the First U.S. Army, Fort Gillem, Georgia; and the Fifth U.S. Army, Fort Sam Houston, Texas. The Second, Fourth, and Sixth U.S. armies were formerly in the continental United States but are now inactive.

The U.S. Army, Europe, has headquarters in Heidelberg, Germany. The command directs the Army's largest permanently based overseas training unit, the Seventh U.S. Army, in Germany. It also directs the Army's largest overseas combat units. The U.S. Army, Europe, commands the U.S. Army Southern European Task Force in Italy. It is part of the U.S. European Command, which coordinates the activities of all American armed forces in Europe.

The U.S. Army, Pacific, commands units and personnel in Hawaii, Alaska, Japan, and the Pacific. It has headquarters at Fort Shafter, Hawaii. It is part of the U.S. Pacific Command, which coordinates the activities of United States armed forces stationed in Hawaii and the eastern Pacific.

The U.S. Army, South, has headquarters at Fort Clayton, Panama. It directs Army forces and personnel in Central America and South America.

The Eighth U.S. Army, Korea, commands and directs forces in South Korea. Headquarters are in Seoul.

The U.S. Army Special Operations Command oversees the operation of Special Forces, Rangers, and other units. Its headquarters are at Fort Bragg, North Carolina.

The U.S. Army Space and Missile Defense Command has headquarters in Arlington, Virginia. It ensures that in a war, the Army will have ready access to space-based military and information-gathering equipment. The command also has the responsibility for defending the United States, and U.S. and allied forces, against missile attack.

The U.S. Army Training and Doctrine Command, with headquarters at Fort Monroe, Virginia, controls all Army individual schooling and training. It sets the Army's standards and requirements. The command also manages the Army ROTC program. In addition, it develops plans for organizing Army forces and assists in the development of combat equipment.

The U.S. Army Materiel Command, with headquarters in Alexandria, Virginia, is responsible for the development, procurement, delivery, supply, and maintenance of equipment, supplies, and weapons for the Army.

The U.S. Army Intelligence and Security Command collects intelligence and performs operations that are related to national security. Headquarters are at Fort Belvoir, Virginia.

The U.S. Army Corps of Engineers is headquartered in Washington, D.C. It is responsible for military engineering and for many civil engineering projects. See **Engineers, Corps of.**

The U.S. Army Medical Command, with headquarters at Fort Sam Houston, Texas, supervises U.S. Army hospitals, and the Army's medical and dental activities around the world. It includes a veterinary command that provides animal care and food inspection services for the entire Department of Defense.

The Military Traffic Management Command handles commercial transportation for military cargo and personnel in the United States. It also operates ocean terminals to move military cargo worldwide. The command is headquartered in Falls Church, Virginia, near Washington, D.C.

The U.S. Army Criminal Investigation Command has its headquarters in Falls Church, Va. It provides criminal investigative services for the Army.

The U.S. Army Military District of Washington provides support for Army headquarters and for official government activities that are in the Washington, D.C., area.

History

The Continental Army, which grew into the United States Army, had its beginning even before the Revolutionary War. All 13 English colonies had militia that fought in the French and Indian wars. Each colony except Pennsylvania had a standing militia which able-bodied men between the ages of 16 and 60 were required to join. In addition, every colony had a volunteer militia. These forces, along with troops who were recruited by the British as *regulars,* fought in the French and Indian War (1754-1763).

On June 14, 1775, the Continental Congress voted to raise 10 companies of riflemen for service in the Revolutionary War and to take charge of colonial militias that were then besieging the British in Boston. The next day, the Congress appointed George Washington "general and commander in chief" of the Continental Army.

In 1776, the Continental Congress established a Board of War and Ordnance to administer the Army. It abolished the board in 1781, and assigned its duties to a secretary at war, who directed the Army and Navy. The United States Congress set up a Department of War in 1789.

The Army probably never had more than 30,000 men at any time. But by the late 1780's, the regular forces had been cut to about 800 men. In 1802, Congress set up the U.S. Military Academy at West Point, N.Y., the nation's first military school.

The War of 1812 (1812-1815). The United States had an army of nearly 12,000 men when it went to war against Britain in 1812. This force reached a peak strength of 38,000 men. Artillery units made important contributions to American victories. Military leaders who won fame in the war included Jacob Brown, Andrew Jackson, and Winfield Scott.

At various times after the war, Congress authorized an army of from 6,000 to 12,000 men. The government used this army to fight two wars against the Seminole Indians and the Black Hawk War against the Sauk and Fox Indians. The Army also forced the Cherokee to move to lands west of the Mississippi River.

The Mexican War (1846-1848) was chiefly a ground war. About two-thirds of the soldiers were members of militia and volunteer units. The Army had to rely mainly on regular army soldiers and 12-month volunteers because of the continual turnover of short-term militiamen. About 104,000 men served during the war, which saw a number of Army "firsts." For the first time, the Army fought far beyond the frontiers of the United States. It used steam vessels as troop transports. American soldiers fought in unaccustomed climate and terrain, and in combat in the streets of Monterrey. Also for the first time, the Army administered a military government over a conquered area.

The Civil War (1861-1865). The United States adopted its first military draft law during the Civil War. Both the North and the South called for volunteers, but not enough men enlisted. On March 3, 1863, Congress passed the Enrollment Act. This law required all men in the North between the ages of 20 and 45 to register for military service.

The Union Army had about 16,000 men under arms in 1860 and reached a peak strength of about 1 million in 1865. Ulysses S. Grant, the Union commander, later became the first person to hold the rank of General of the Army. During the war, the Union Army made wide use of railroads, telegraph, photography, observation balloons, and rifled artillery.

Within 10 years after the Civil War, the Army had been reduced to about 25,000 men. Its soldiers were toughened by years of Indian fighting. However, few had experience handling problems of war mobilization and large-scale command.

The Spanish-American War (1898). The Regular Army had only 28,000 men when war broke out with Spain. The National Guard numbered about 100,000. Congress authorized a twofold increase in the size of the Army, and an initial enlistment of 125,000 volunteers. As the war progressed, inadequacies in Army organization and preparedness became apparent. The problems of supply, health, and sanitation in the tropics were as dangerous as the Spanish troops in Cuba and the Philippines. More soldiers died from disease than were killed in battle.

After the war, the Army helped establish American

Important dates in Army history

1775 The Continental Congress created the Continental Army to fight in the Revolutionary War.

1789 Congress established the Department of War to direct military affairs.

1802 The U.S. Military Academy, first military school in the United States, opened at West Point.

1847 During the Mexican War, the U.S. Army administered a military government over an occupied area for the first time.

1863 Congress passed the first draft law in the United States, the Enrollment Act.

1903 The Army adopted the general staff system and set up the Office of the Chief of Staff, United States Army.

1914 The Panama Canal, a project of the Army engineers, was completed, linking the Atlantic and Pacific oceans.

1917 (April 6) The United States declared war on Germany.

1944 Army troops and other Allied forces stormed Normandy, France, in the greatest amphibious attack in history.

1945 Atomic bombs, developed by U.S. Army and by civilian scientists, were dropped on Hiroshima and Nagasaki in Japan.

1958 The Army fired the Explorer 1 earth satellite into orbit with its Jupiter-C missile.

1965 The Army's first airmobile division was activated at Fort Benning, Ga., and shipped to Vietnam.

1973 All U.S. combat troops withdrew from Vietnam after a cease-fire agreement was signed.

1974 The Army achieved all-volunteer status at full authorized strength.

1976 Women were admitted to the U.S. Military Academy.

1991 The Army led a land attack on Iraqi forces in the Persian Gulf War, resulting in Iraq's defeat within several days.

authority in the Philippines. It also fought in the Boxer Rebellion in China (see **Boxer Rebellion**).

The early 1900's were a period of reorganization for the Army. Through the efforts of Secretary of War Elihu Root, Congress approved the adoption of the general staff system and the appointment of a chief of staff to replace the commanding general of the Army. On Aug. 15, 1903, Lieutenant General Samuel B. M. Young became the first chief of staff.

On Aug. 1, 1907, the Army set up an aeronautical division within its signal corps. This force of one officer and two enlisted men slowly grew until it became an independent military service 40 years later (see **Air Force, United States**).

World War I (1914-1918). The United States had a Regular Army of only 128,000 men when it declared war on Germany on April 6, 1917. But the National Guard had developed into a military organization far superior to the state militias of earlier wars. However, with the need for a larger army, Congress passed a Selective Service Act that made all able-bodied men between the ages of 21 and 30 (later, 18 and 45) subject to military service. The government sent nearly 2 million soldiers overseas in the American Expeditionary Forces. By the summer of 1918, American manpower and arms had helped turn the tide of battle in favor of the Allies. General John J. Pershing commanded the American doughboys who fought in France. The Meuse-Argonne offensive marked the Army's greatest battle up to that time. But, with the signing of the armistice in 1918, the Army again faced a cutback in strength. Within two years, it had been reduced to about 204,000 men, and it was reduced to even fewer in the following postwar years.

After World War I, U.S. Army troops came to the aid of anti-Communist forces in the Russian civil war. However, they accomplished little and soon were brought home.

World War II (1939-1945) witnessed the mobilization of the largest American army ever to take the field. The Army expanded from about 190,000 men in 1939 to almost 8,270,000 in 1945. The Selective Service Act of 1940 required all male citizens age 21 through 35 to register for a year of military service. Later amendments to the law extended the age limits to 18 and 44 and increased the length of service to the duration of the war. The first drafted men entered the Army on Nov. 18, 1940. The Army multiplied its units by means of the cadre system. A certain number of key men were removed from a unit as it became ready for service. This nucleus of men, or *cadre,* formed the basis of new units.

General George C. Marshall became Army chief of staff on Sept. 1, 1939, the day that Germany attacked Poland. Japan's attack at Pearl Harbor on Dec. 7, 1941, plunged the United States into war.

The Army underwent several reorganizations during World War II to cope with the complexities of fighting on many battlefronts. Lieutenant General Lesley J. McNair became commander of U.S. Army Ground Forces. General Henry H. Arnold commanded the Army Air Forces.

The Army took part in the greatest amphibious attack in history when the Allies landed in Normandy, France, in 1944. It organized airborne divisions that added a new dimension to warfare (see **Airborne troops**). Its engineers cooperated with civilian scientists to develop the atomic bomb (see **Nuclear weapon**).

In May 1942, the Army established the Women's Army Auxiliary Corps (WAAC). In 1943, the WAAC became a part of the United States Army, and the name was changed to Women's Army Corps (WAC). Women in the Army became known as *Wacs.* More than 17,000 Wacs served overseas during the war. In 1945, the last year of the war, the WAC reached a peak strength of about 100,000 enlisted women and officers. The WAC was dissolved in 1978.

At the end of the war, the Army faced the huge problem of *demobilization* (releasing millions of soldiers from active duty). By 1948, it had about 554,000 soldiers. The government discontinued the draft in 1947, but resumed it in 1948.

The Korean War (1950-1953). In response to a United Nations (UN) request, President Harry S. Truman in June 1950 ordered U.S. Army troops on occupation duty in Japan to aid South Korea. General of the Army Douglas MacArthur headed the UN Command in Korea. Generals Matthew B. Ridgway and Mark W. Clark later succeeded MacArthur.

During the war, the Army gained considerable experience in training and outfitting troops of many nationalities. The Army, which had 593,000 soldiers before war broke out, had 1,596,000 by June 1952. But its strength was less than 1 million by June 1957.

The atomic age Army. In 1953, the first atomic artillery shell was fired in a test at Frenchman Flat, Nev.

In the early 1960's, the Army completed several reorganizations. For example, it completed a plan called Reorganization Objectives, Army Division (ROAD) to increase the flexibility of its fighting forces in limited wars. In 1962, the reorganization added a *mechanized* division to the three existing types: infantry, airborne, and armored.

In 1965, the Army added an *airmobile* division. This division was to use helicopters and airplanes to support its ground units in combat.

The Vietnam War (1957-1975). United States involvement in the struggle to prevent Communist forces from taking control of South Vietnam began in the mid-1950's. At first, the Army contributed only advisers to South Vietnamese government forces. But by 1965, the U.S. commitment to South Vietnam had grown, and large Army units went into action. The airmobile division proved very effective in a war that required the ability to strike with surprise. The helicopter was a major weapon. It was used as an armed attack troop and cargo carrier, as well as an ambulance.

United States Army strength in Vietnam reached a peak of about 363,000 in April 1969. In the early 1970's, the South Vietnamese assumed increasing responsibility for their own defense. By December 1972, about 14,000 U.S. Army troops remained. An agreement for a cease-fire in Vietnam was signed in Paris on Jan. 27, 1973. All U.S. ground troops left Vietnam shortly after the agreement was signed. But the war did not end until 1975.

Reorganizations. In 1973, the U.S. government ended the military draft, and the armed services began recruiting all-volunteer forces. The same year, the Army began a reorganization designed to cut personnel and

Combat troops train regularly to maintain their readiness to fight. Members of the 82nd Airborne Division practiced desert maneuvers in 1990, *shown here.* The division fought in the Persian Gulf War in 1991.

operating costs and improve readiness and efficiency. It included the establishment of the Forces Command and the Training and Doctrine Command.

In the mid-1980's, the Army worked to reduce the amount of equipment and number of soldiers of its heavy divisions while keeping their combat abilities intact. Light infantry forces were redesigned so they could move rapidly anywhere in the world. Army corps were provided with more artillery, aviation, and air defense capabilities.

The Persian Gulf War. In August 1990, Iraq invaded neighboring Kuwait. The United States, to prevent further aggression in the area by Iraq, began sending troops to Saudi Arabia. Troops from Britain, Egypt, and other nations soon joined those of the United States. By November, over one-third the total forces of the U.S. Army, including about 149,000 soldiers of the Army Reserve and National Guard, had been mobilized for war.

War began on Jan. 16, 1991, U.S. time, which was January 17 in Iraq. At first, the allied forces bombed military targets in Iraq and Kuwait. On February 23 U.S. time (February 24 in the war area), allied land forces began moving into Kuwait and Iraq. The allies quickly defeated the Iraqi forces there, suffering few casualties. Two days later, the Iraqi troops began withdrawing from Kuwait.

Army worm is a caterpillar especially harmful to corn and other grains, and garden crops east of the Rocky Mountains in the United States and Canada. It is the *larva* (young) of a night-flying moth (see **Larva**). Sometimes large numbers of these caterpillars march like an army across fields. They stick together in dense patches and sometimes form processions 12 or 14 feet (3.7 or 4.3 meters) long and 2 or 3 inches (5 or 8 centimeters) wide. They apparently band together to search for new feeding grounds.

The army worm is hairless and fleshy. It is about 1 $\frac{1}{2}$ inches (3.8 centimeters) long, and has green and yellow stripes. When full grown, it burrows into the soil and transforms into a *pupa* (see **Pupa**). The pupa changes into a pale brown moth that emerges in the spring. The female moth deposits strings of eggs on the lower leaves of grasses. The caterpillars hatch from these eggs. They usually feed at night and hide during the day. There are two or three broods per year.

Farmers fight army worms with poisoned bran mash and with such insecticide sprays as carbaryl and methomyl. Dust *furrows* (narrow grooves) may be dug as barriers against them. The natural enemies of the army worm include parasitic flies and wasps, and the fiery ground beetle. Charles V. Covell, Jr.

Scientific classification. The army worm is in the family Noctuidae. It is *Pseudaletia unipuncta.*

See also **Moth.**

Arnica, *AHR nuh kuh,* is the name of about 45 kinds of plants of the Northern Hemisphere that yield a juice used to drive away the blood that collects in bruises.

WORLD BOOK illustration by Christabel King

The mountain arnica bears heads of golden-yellow flowers from its stem. The plant grows in northern and central Europe.

The *common,* or *mountain, arnica* is the source of commercial arnica. It has a twisted root that lives from year to year. Its stem is about 2 feet (61 centimeters) high and bears heads of golden-yellow flowers. Every part of the plant contains *arnicin,* which is used to make the medicine. Mountain arnica is native to the mountain meadows and moors of northern and central Europe.

W. Dennis Clark

Scientific classification. The mountain arnica is in the composite family, Asteraceae or Compositae. It is *Arnica montana.*

See also **Composite family.**

Arno River rises in the Etruscan section of the Apennine Mountains in northwestern Italy. It flows west for about 150 miles (241 kilometers) and empties into the Ligurian Sea (see **Italy** [terrain map]). Only about 20 miles (32 kilometers) of the Arno can be used for navigation. Florence and Pisa lie along the river. The fertile Arno Valley has vineyards and olive groves, and is noted for its scenic beauty. See also **Florence; Pisa.** Hugh D. Clout

Arnold, Benedict (1741-1801), was an American general of the Revolutionary War period. Once trusted and admired, he became the most famous traitor in United States history.

Arnold was born on Jan. 14, 1741, in Norwich, Connecticut. He learned the *apothecary* (pharmacy) trade and, in 1762, opened a book and drug store in New Haven, Connecticut. Arnold also carried on trade with the West Indies. By 1774, he was one of the wealthiest citizens in New Haven. In 1767, Arnold married Margaret Mansfield, who was the daughter of the sheriff of New Haven County. She died in 1775.

A courageous soldier. In 1774, Arnold became a captain in the Connecticut militia. Soon after the Revolutionary War began in 1775, he was commissioned as a colonel in the patriot forces. Arnold and Ethan Allen led 83 men in the attack and capture of Fort Ticonderoga, in New York, on May 10, 1775.

Later that same year, Arnold led 1,100 soldiers into Canada. He and General Richard Montgomery worked together in an unsuccessful assault on Quebec. Arnold's leg was severely wounded in the assault, and his courage won him a promotion to brigadier general. In October 1776, he distinguished himself during the Battle of Valcour Island, a naval battle on Lake Champlain.

A disappointed officer. Arnold had several disappointments. He was passed over for promotion in February 1777, when Congress appointed five new major generals. Arnold, who had more seniority than any of the men promoted, was talked out of leaving the army by General George Washington. In May 1777, Congress promoted Arnold to major general as a reward for his bravery in helping drive a British raiding party out of Connecticut.

Later that year, Arnold served under General Horatio Gates against the British general John Burgoyne. In October 1777, in the Second Battle of Free-

Engraving by H. B. Hall
Historical Pictures Service

Benedict Arnold

man's Farm, Arnold showed courage against Burgoyne and was again badly wounded. This battle, won by the patriots, is also known as the Battle of Bemis Heights. Burgoyne's defeat led to his surrender at Saratoga days later. Gates received credit for the victory. Congress voted Arnold the country's thanks and had Washington restore Arnold's seniority over the other generals.

In 1778, Arnold took command of Philadelphia. There he married Margaret Shippen, a young woman from a prominent family. Arnold was not a good administrator, and he drew criticism for living extravagantly. The executive council of Pennsylvania accused him of being too gentle with Americans who opposed independence from Britain. The council also accused him of using military personnel to do personal favors. A court-martial cleared Arnold, but it ordered General Washington to reprimand him.

Turns traitor. Arnold brooded over what he considered his country's ingratitude and injustice, and he began corresponding with the enemy. Arnold was in command of West Point in 1780, and he worked out a plan to surrender that important military base to the British commander Sir Henry Clinton.

The capture of British Major John André, who was carrying papers sent by Arnold to Clinton, exposed Arnold's treachery (see **André, John**). Arnold escaped to New York City and became a brigadier general in the British Army. He demanded 20,000 pounds from the British for the losses he incurred in joining them. But he received only 6,315 pounds. As a British officer, he led expeditions that burned Richmond, Virginia, and New London, Connecticut.

Scorned in England. Arnold was received warmly by King George III when he went to England in 1782, but others there scorned him. In 1797, the British government granted him 13,400 acres (5,423 hectares) in Canada, but the land was of little use to him. He spent most of his remaining years as a merchant in the West Indies trade. In his last days, Arnold was burdened with debt, became discouraged, and was generally distrusted. He died on June 14, 1801. James Kirby Martin

Wade, Mary D. *Benedict Arnold.* Watts, 1995. Younger readers.

Arnold, Eddy (1918-), an American singer, was a leading performer in country music from the mid-1940's through the 1960's. He was a pioneer in gaining a mass audience for country music. His best-known songs include "Cattle Call" (1944), "I Really Don't Want to Know" (1954), "You Don't Know Me" (1956), "Tennessee Stud" (1959), and "Make the World Go Away" (1965).

Arnold, known as "the Tennessee Plowboy," was born near Henderson, Tennessee, on May 15, 1918. His mother taught him to play the guitar. In 1936, Arnold became a radio performer. His increasing popularity as a singer on the radio gained him a recording contract with RCA Victor in 1943. Arnold hosted several country music shows on television from 1952 to 1956. Lee Rector

Arnold, Henry Harley (1886-1950), developed the small United States Army Air Corps into a large, powerful U.S. Air Force. Arnold commanded the Army Air Forces during World War II. He was the only person to serve as both General of the Army and General of the Air Force.

Arnold was born on June 25, 1886, in Gladwyne, Pennsylvania. He was nicknamed "Hap." He graduated from the United States Military Academy (West Point) in 1907, and took flying lessons from the Wright brothers. During World War I (1914-1918), he organized the air defense of the Canal Zone. After the war, he transferred to the newly formed Air Service. He made many experimental flights, including the first mass flight of B-10 bombers. He helped start air mail flights, air refueling, and air forest fire patrols.

U.S. Air Force
Henry H. Arnold

Before and during World War II (1939-1945), Arnold fought for expansion of U.S. air power. He became chief of the Army Air Corps in 1938 and U.S. deputy chief of staff for air in 1940. Arnold was made chief of the new Army Air Forces in 1941 and commanding general in 1942.

As a member of the Joint Chiefs of Staff, Arnold successfully asked for daylight precision bombing against Germany. Previous bombing raids had been staged at night because they were thought to be safer. Daylight bombing increased accuracy because the targets could be seen. Arnold retired in 1946 and died on Jan. 15, 1950.

Maurice Matloff

Arnold, Matthew (1822-1888), was one of the intellectual leaders of Victorian England. He ranks with Lord Tennyson, Robert Browning, and Gerard Manley Hopkins among the greatest Victorian poets. Arnold was also the most important English literary critic of his time. He was a major social critic, and wrote important works on religion and education.

Arnold's poetry expresses his experience during an age when traditional religious beliefs and certainties were being questioned without new beliefs to take their place. As he wrote in *Stanzas from the Grande Chartreuse* (1855), he felt himself to be

> Wandering between two worlds, one dead,
> The other powerless to be born ...

Arnold's most famous poem, "Dover Beach," describes the "melancholy, long, withdrawing roar" of the "Sea of Faith." His poetry resembles the poetry of our own time in its yearning for peace and its portrayal of personal loneliness. Faced with these difficulties, Arnold often counseled resignation and endurance.

Arnold's prose includes the literary criticism in *Essays in Criticism* (1865, second series 1888) and the social criticism of *Culture and Anarchy* (1869). Arnold judged both literature and Victorian society according to the standard of "the best that is known and thought in the world." He found recent writers of his time such as Percy Bysshe Shelley, William Wordsworth, or Robert Burns inadequate when measured against Homer, Dante, or William Shakespeare. Arnold condemned what he felt was the

tendency toward *anarchy* (lawlessness) in Victorian culture. Arnold found his society resisting the new ideas that come from a "free play of the mind," which he highly valued. He hoped that maintaining high standards of judgment would aid the return of better literature and a better society.

Arnold was born on Dec. 24, 1822, in Laleham. His father was Thomas Arnold, headmaster of Rugby, the famous English secondary school. Arnold attended Rugby and Oxford University.

In 1851, Arnold became an inspector of schools for the British government, a post at which he worked hard for the next 35 years. Most of his poems were published between 1849 and 1855. His prose appeared after 1855. Arnold served as professor of poetry at Oxford from 1857 to 1867. He died on April 15, 1888. K. K. Collins

Arp, *ahrp,* **Jean,** *zhahn* (1887-1966), was a French sculptor. He was also called Hans Arp. He worked with many materials, including wood, bronze, and polished stone. Arp became famous for his reliefs, free-standing sculptures, and collages (see **Collage**). While Arp's works may at first seem abstract, many of them suggest plants, animals, and human anatomy. These organic forms capture the life, vitality, and sense of growth found in nature, rather than specific physical appearances.

Arp avoided preconceived plans when creating his works. He let the sculpture "create itself" in such works as *Shepherd of the Clouds* (1953).

Arp was born on Sept. 16, 1887, in Strasbourg. He was also a painter, poet, and graphic artist. He exhibited with the German Expressionist artists just before World War I (1914-1918). In 1916, he helped found Dadaism. He was later associated with the Surrealists (see **Dadaism; Surrealism**). He died on June 7, 1966. Joseph F. Lamb

Árpád. See **Hungary** (History).

Arpino, *ahr PEEN oh,* **Gerald** (1928-), is an important American ballet *choreographer* (dance creator). Arpino's career has been closely identified with the American choreographer Robert Joffrey. Arpino and Joffrey cofounded the Joffrey Ballet (now the Joffrey Ballet of Chicago) in 1956. Arpino was a principal dancer with the company until 1964 and then served as its chief choreographer. He became the company's artistic director after Joffrey died in 1988.

Gennaro Peter Arpino was born on Jan. 14, 1928, in the New York City borough of Staten Island. He made his debut as a choreographer in 1961 with *Ropes and Sea Shadows.* His other works include *Viva Vivaldi!* (1965), *Trinity* (1970), *Kettentanz* (1971), *Celebration* (1980), *Light Rain* (1981), *Billboards* (1993), and *Partita for RC* (2000). Dan Zeff

Arquebus. See **Harquebus.**

Arrest is the act of taking a person into the custody of the law and depriving the person of liberty. The term comes from the French word *arrêter,* which means *to stop.* Any police officer may make arrests. Agents of the Federal Bureau of Investigation also have the power to make some types of arrests. Private citizens have the right to make an arrest if a serious crime is committed in their presence. People may be arrested after they are accused of murder, theft, or other criminal offenses. For some crimes, and under certain conditions, a police officer must obtain a court order called a *warrant* before making an arrest. But an officer does not need a warrant to arrest a person in the act of committing a crime. Ordinarily police may arrest anyone whom they reasonably believe to be guilty of a serious crime.

Usually only those people accused of such serious crimes as murder are forced to stay in jail until they are brought to trial. Other people may go free until trial if they can provide a sum of money called *bail.* This money is a pledge to appear for trial. In 1991, the Supreme Court of the United States ruled that a person arrested without a warrant has the right to be heard before a judge within 48 hours after the arrest. George T. Felkenes

Arrhythmia, *uh RIHTH mee uh,* is an abnormal heart rhythm. Arrhythmias often are extra heartbeats that cause no serious problems. However, sometimes the heart rhythm can become dangerously slow or fast.

Abnormally slow heart rhythms often are a sign of *heart block,* in which the electrical impulses started by the heart's natural "pacemaker" fail to be conducted to the *ventricles,* the heart's main pumping chambers. The heart rate becomes very slow, which may cause loss of consciousness, heart failure, or death. A doctor can correct the condition by implanting an electronic *pacemaker* in the body. This device transmits an electric impulse to the heart, stimulating it to beat in a normal rhythm.

Abnormally fast heart rhythms are the chief cause of disabling symptoms or death from heart disease. Such arrhythmias can occur unexpectedly in the months or years after a heart attack. Many can be controlled with medication. In serious emergencies, they can be treated by applying a strong electric shock, but the shock must be administered within minutes to prevent severe heart damage or death. In some cases, doctors implant a device called a *defibrillator* to detect and treat abnormally fast heart rhythms. The defibrillator monitors the heart and automatically delivers electric shocks before the arrhythmia causes permanent damage. Toby R. Engel

Arrow. See **Archery.**

Arrow, Kenneth Joseph (1921-), an American economist, shared the 1972 Nobel Prize in economics with Sir John Hicks of the United Kingdom. They won the award for their contributions to general equilibrium theory and to welfare economics. General equilibrium theory examines the relationship between the processes of production, distribution, and consumption in the total economy. Welfare economics is a branch of economics concerned with how an economic system might achieve the greatest possible welfare for its people.

Arrow is best known for his impossibility theorem, an idea that revolutionized welfare economics. The theorem proves mathematically that a perfect form of government can never be possible. Arrow also has done pioneering research on the theory of business risks.

Arrow was born in New York City on Aug. 23, 1921. He taught economics at Stanford University from 1949 to 1968 and at Harvard University from 1968 to 1979. Arrow returned to Stanford in 1979. His books include *Essays in the Theory of Risk Bearing* (1971) and *The Limits of Organization* (1974). Barry W. Poulson

Arrowhead is the striking end of an arrow. It is usually a separate piece attached to the front of the arrow shaft. Prehistoric people fashioned arrowheads of stone or

American Indian arrowheads were fashioned in many shapes and sizes and from a variety of materials. The Indians sharpened such minerals as jasper, quartz, and flint into deadly points.

bone for use in hunting and warfare. No one knows just when or where people first used the bow and arrow.

The American Indians made few stone arrowheads before A.D. 500. Earlier Indians commonly used stone-headed spears instead. The Indians made arrowheads of argillite, chalcedony, jasper, obsidian, quartz, quartzite, slate, and flint. The maker first split off pieces from a large stone, using a heavy rock as a hammer. Then, the maker selected a piece of suitable size and thickness. Grasping it between the palm and fingertips of one hand, the maker pressed the stone's upperside near one edge with an antler, bone, or ivory tool. This process, called *pressure flaking,* removed a small chip from the underside of the arrowhead. The maker repeated this process until the stone took the desired shape.

Indian arrowheads differ in size, shape, thickness, and surface finish. They vary in length from more than 2 inches (5 centimeters) to less than $\frac{1}{2}$ inch (13 millimeters). Some arrowheads are roughly triangular, and others are oval or leaf-shaped. Archaeologists can recognize the various types of arrowheads made by Indians of different time periods or geographic regions. Indians stopped making stone arrowheads after traders furnished them with iron. T. Patrick Culbert

Arrowroot is a plant cultivated in many tropical countries. People use the *rhizomes* (underground stems) of the arrowroot plant to make a light starch that is used in puddings, pie fillings, and other dessert mixtures. The starch obtained from the plant is also called *arrowroot.* See also Starch.

Scientific classification. The arrowroot plant belongs to the arrowroot family, Marantaceae. Its scientific name is *Maranta arundinacea.* Michael J. Tanabe

Arroyo. See Desert (Desert land and climate).

Arsenic, *AHR suh nihk* or *AHRS nihk,* is a semimetallic chemical element. It is a deadly poison, and prolonged low-dose exposure to arsenic causes cancer in human beings. Many rat poisons, insecticides, and weedkillers contain arsenic. It is also used to manufacture lead gun shot and certain types of electrical equipment, and to increase the strength of certain alloys.

There are three chief *allotropes* (solid forms) of arsenic: (1) gray arsenic, (2) yellow arsenic, and (3) black arsenic. Gray arsenic is the ordinary, stable form of the element. It has a shiny appearance and is a moderately good conductor of heat and electricity. But gray arsenic is brittle and breaks easily. When heated to 1135 °F (613 °C), gray arsenic *sublimes*—that is, it passes directly into a vapor without melting (see **Sublimation**).

Arsenic occasionally occurs in its pure form in nature. But it is most commonly found in chemical combination with sulfur or oxygen, or with such metals as cobalt, copper, iron, nickel, silver, and tin. The principal arsenic-containing mineral is arsenopyrite. The most widely used arsenic compound is *white arsenic,* also called *arsenic trioxide.* It is usually produced as a by-product of the *smelting* (melting) of copper or lead.

Compounds of arsenic have been used since ancient times for many purposes, including medicines and poisons. The German scholar Albertus Magnus is often credited with first isolating the element about 1250. Ar-

senic has the chemical symbol As. Its atomic number is 33, and its atomic weight is 74.9216. Marianna A. Busch

See also Arsenical; Insecticide.

Arsenical, *ahr SEHN uh kuhl,* is one of a group of drugs that contain arsenic and have been used as a medicine. *Carbarsone* is an arsenical used in treating amebic dysentery. Arsenic is a deadly poison. Arsenicals are being replaced by other drugs.

Christopher A. Rodowskas, Jr.

See also Arsenic.

Arson, *AHR suhn,* is the crime of willfully and maliciously damaging or destroying a building or other property by fire or explosion. In most states of the United States, arson includes burning one's own property to collect insurance payments on it. In some cases, arson is committed for revenge against a building owner or occupant. Other fires are set to destroy evidence of another crime, such as murder or burglary. Still other arson cases result from vandalism or *pyromania,* an uncontrollable urge to set fires (see Pyromania). Arson is difficult to prove in most cases because fire can destroy almost all evidence of the crime. Also, most cities lack enough trained arson investigators.

The police and fire departments of most major cities have formed arson squads and are training their members to investigate cases of suspected arson. Insurance companies have become increasingly unwilling to pay for losses resulting from fire unless a thorough investigation has been made. Many fire departments have called for the adoption of stronger laws against arson.

Charles F. Wellford

Art, Commercial. See Commercial art.

Art and the arts. In a broad sense, art is skill in making or doing. We can say that someone knows and practices the art of basket-weaving, of tuning a piano, or even of hitting a home run. In this sense, there are many arts—as many as there are kinds of deliberate, specialized activities for human beings to engage in.

The word *art* is used in many other ways. Some people speak of *the useful arts* as the ones that produce beautiful objects for everyday use, and *the decorative arts* as those that produce beautiful objects for their own sakes. Schools offer *liberal arts* courses in such topics as history and philosophy, and *applied arts* courses in such subjects as architecture and mechanical drawing. Teachers use the term *language arts* to mean the related skills of reading, writing, speaking, and spelling. Many people speak of *the graphic arts* as those involved in printing and bookmaking.

The word *art* is often used in a more specialized way to mean *fine arts,* such as painting pictures, writing novels, or composing music. Things created as the result of such activity are supposed to be different from, and more valuable than, things that require mere craftsmanship or technical skill. Some traditional fine arts are poetry, fiction, opera, painting, sculpture, drama, and ballet. Today architecture, motion pictures, photographs, pottery, weaving, and some forms of modern dancing are also considered art in this special sense.

The reasons for art

Human beings are makers of many things, and they make them for many purposes. Some creations serve obvious practical needs. For example, people have always made tools for cutting, digging, killing, and eating. But in all cultures, people also seem to have two less obvious purposes for some of the objects they make. First, they want to make things in forms that give pleasure when seen or heard. Second, people want to make objects that will remind them, and also teach other people, about their most important discoveries regarding fundamental realities. We call these reasons for making and valuing art *formal* and *cognitive* interests.

Formal interest. People have always had an interest in order. Most of us enjoy experiencing patterns that display balance and contrast. Prehistoric people carved the handles of their hunting knives in regular, pleasing patterns. In the 1800's, American cowboys liked to have guns and saddles decorated with patterns. We experience the same delight in form or design when we buy clothes or automobiles for their appearance rather than their warmth or efficiency. Perceiving works of art has long been considered a little like understanding mathematics because both involve patterns or forms.

Cognitive interest refers to meaning. Certain events and ideas take on the highest importance in our religious, social, moral, political, and personal lives. People have always used formal symbols or performances to make such events meaningful or to signify such ideas so they can be transmitted from person to person and from generation to generation. Prehistoric people used dances and paintings to communicate the idea of success in planting, harvesting, and hunting. The ancient Greeks gave their ideas about such ideal human qualities as wisdom and courage visual form in their beautiful statues of gods and goddesses. Today, we still give occasions like graduations or weddings importance through music and song. We also try to understand the meaning of important personal events, such as falling in love, and important public events, such as wars, by composing music, writing novels and poetry, painting pictures, or making films about them.

The work of art

The aesthetic experience. Works of art result when the formal interest and the cognitive interest come together in the creative process through which artists make art. In general, art presents us with forms we enjoy perceiving and invites us to recall or learn something important. But we do not feel these interests separately when we appreciate art. Art gives us a special kind of experience that unites pleasure in perceiving orderly forms and in learning. Scholars call this the *aesthetic experience.*

The Greek epic poem the *Odyssey* appeals to us in a way that joins the two interests. It is a story about basic human problems and a study of the resourcefulness and adaptability of human nature. It is also a well-formed story, with episodes following each other in a way that builds toward the climax. The poem's words form images in our minds and tell us about the feelings that go with the story. As we read or listen to the *Odyssey,* our experiencing of the formal features enriches our understanding of the meaning. In the same way, Vincent van Gogh's painting *Sunflowers* is more than a formal composition of shapes and colors. It has a bright vividness that stays in our experience as a symbol of how nature

Creating and enjoying art rank among humanity's most important activities. Some people like to express themselves through art as a form of recreation, *above left.* Others become professional artists, *lower left.* Art masterpieces can be studied, *right,* for pleasure and to learn how artists throughout history have felt about such subjects as love, religion, and social justice.

bursts with life. For other examples of the way formal and cognitive interests come together, see **Painting** (What do painters paint?).

Works of art differ widely in how they combine formal features with meaning. Toward one end of the scale, where the cognitive interest is strongest, are such works as the tragedies of Shakespeare. These works explore fundamental human situations and move us profoundly. They reward us with the discovery of more subtle and complex meaning as we read them or see them performed again and again. Similarly, we enjoy experiencing the religious paintings of the Italian Renaissance, the great novels of Charles Dickens, and Johann Sebastian Bach's Mass in B minor. These works of art do more than convey religious and moral beliefs and attitudes. They convey these meanings through delightful design and pleasurable patterns of perception.

Toward the other end of the scale is art that evokes strong formal interest but weak cognitive interest. This is true of the paintings of the modern American painter Frank Stella. It is also true of Bach's Preludes and Fugues and Joseph Haydn's chamber music, where the melody and counterpoint emphasize musical form. The formal patterns of classical music, as well as ballet and even the freer forms of modern dance, produce pleasure by satisfying our interest in experiencing orderly shapes and sequences. Most such works are not vehicles for philosophical themes. Yet, even here, some critics give interpretations of highly formal art that show how such works are meaningful. They point out that Stella's paintings contrast with El Greco's to show how curved shapes can define a painting's perceived surface as depicting stillness or motion (see the illustrations with this article). The formal patterns of music have qualities like joy, sadness, and vitality, which reflect features found in human life.

Beauty. Some people identify the formal interest with our desire to make and enjoy beautiful things. But others prefer to use the word *beauty* in a fuller sense. They say that the sheer satisfaction we feel when we perceive

complex but balanced design, and the profound satisfaction we experience in understanding complex but clear meaning, both contribute to beauty.

Even in the fuller sense, whether a thing is beautiful does not depend on its being useful. Many paintings, poems, and musical compositions have no use apart from their value as works of art. Of course, we could use van Gogh's *Sunflowers* as a sign for a florist's shop, or we could use a piece of sculpture to hold a door open, but their real function is to be art. Such objects as chairs, dishes, and vases have useful functions. Yet some of these works are considered art and displayed in museums because they illustrate something of aesthetic importance in their design.

Grouping the arts

Generally speaking, works of art have certain things in common. Each presents something to our sense-perception, such as the music we hear, or to our imaginative contemplation, like the story we read. Each one is set off from other things in some way. For example, a statue stands on a pedestal, and a play takes place on a stage. This way of setting the work off helps us grasp it as a whole. The work is always more or less complicated. For instance, the play has several characters, the painting consists of several shapes or colors, and the music contains a variety of sounds. The work is always organized to some degree into a unified whole.

At the same time, works of art differ in important ways. Some, such as operas and novels, can tell a story. Others, like chamber music, do not. Some, such as music and poetry, take time to unfold. Still others, like painting, are presented all at once. But this difference should not be stressed too much, because it takes time to see a painting fully, just as it does to listen to a symphony. Some kinds of art, such as sculpture, come to us just as they left the hands of their creators. Other kinds are performed or interpreted. The orchestra plays music or the actors perform the play.

But perhaps the most fundamental way of classifying works of art is in terms of the kinds of elements that make them up. Arts that use words differ from those that do not, because words introduce a special sort of reference into the arts.

Herman Miller Inc. (WORLD BOOK photo)

The useful arts bring beauty and imaginative design to many everyday objects. The chairs shown above are considered works of art as well as practical pieces of furniture.

Verbal art is literature, which can be divided into poetry, fiction, and the essay. Literary critics have suggested a number of ways by which to distinguish literary works from other kinds of writing, such as science or history. See **Literature**.

Nonverbal arts include two main types: (1) musical composition and (2) visual design. Works that consist of patterns of sound, pitch, or rhythm are *musical compositions*. Even a simple melody, or a drum solo with no melody, can be considered music. Works that consist of patterns of line, shape, and color are *visual designs*.

The arts can be divided even further. For example, we can divide visual designs according to the kinds of materials that are used and the way the designs are produced. In this way, we can distinguish photographs and prints from paintings. In a group of prints, we can separate etchings from lithographs. Pictures may be painted with oils or water colors.
